In fact, since x may be supposed as small as we please, it is always possible to render the sum of all the terms of the given equation which have x for a factor as small as we please; that is, the sum of all the terms following the first may be rendered as small as we please. Hence the first term differs from zero only by a quantity which may be less than any assignable quantity; but the first term A being constant, its difference from zero cannot be any finite quantity assumed at pleasure, for this would suppose it to be variable. It follows, therefore, that A can be nothing else than zero; that is, we must have $A = 0$, whence there remains

$$Bx + Cx^2 + Dx^3 + \&c. = 0.$$

Divide this last equation by x, and there results

$$B + Cx + Dx^2 + \&c. = 0;$$

and, for the same reasons as before, it is manifest that we must have $B = 0$. Proceeding in the same manner, we find successively $C = 0$, $D = 0$, &c.

The principle here explained is extremely fertile in applications, and in fact gives the means of resolving by ordinary algebra all the questions which are considered as belonging to the infinitesimal analysis. The respective procedures of both methods, when properly simplified, are absolutely the same; all the difference consists in the manner of viewing the subject.

I'NDEX. In Bibliography, an alphabetical table, containing the principal subjects of a work, or words employed in it, with references to the part of the work in which they are to be found. Many independent works, containing catalogues of various kinds, have been also entitled index.

I'NDEX. (Lat. indico, *I point out*.) A term often applied to the fore finger.

I'NDEX. In Music, the same as *Direct*, which see.

I'NDEX EXPURGATO'RIUS. A catalogue of works, which the church of Rome prohibits the faithful from reading, or condemns as heretical. It is annually published at Rome.

I'NDEX OF A QUANTITY, in Arithmetic and Algebra, is used in the same sense with *exponent*. Thus, in the expression $(a + b)^3$, 3 is the index, and denotes that the quantity $a + b$ is to be raised to the third power, or cube. The index of a logarithm, or its *characteristic*, is the figure prefixed to the logarithm for the purpose of indicating the unit's place in the corresponding number. *See* LOGARITHM.

I'NDEX OF REFRACTION, in Optics, expresses the constant ratio which exists between the sines of the angles of incidence and refraction. Thus, with respect to a ray of light falling obliquely on the surface of water, the sine of the angle of incidence is found by experiment to be to the sine of the angle of refraction in the constant ratio of 1·336 to 1. Hence 1·336 is the index of refraction in water. *See* REFRACTION.

INDIAN ARCHITECTURE. *See* ARCHITECTURE.

INDIAN INK. A species of ink used in Europe for the lines and shadows of drawings. It is principally manufactured in China, and there used for writing. From the experiments of Dr. Lewis, it appears to be a compound of fine lampblack and animal glue. *See* INK.

I'NDIANITE. A mineral which occurs in granular masses, associated with garnet, felspar, and hornblende. It is hard enough to scratch glass, and of a white or gray colour.

INDI'CATIVE MOOD. (Lat. indico, *I point out.*) That form of a verb which expresses a simple or unconditional judgment. *See* GRAMMAR.

I'NDICATOR. (Lat. indico.) A genus of birds belonging to the cuckoo tribe (*Cuculidæ*), characterized by a straight finch-like bill, with compressed sides and a triangular base, the culmen and gonys being equally inclined towards the tip, and the gonys angulated; wings lengthened, pointed; tail moderate, rounded; feet short; middle toe much longer than the tarsus.

The species of *Indicator* are remarkable for their habit of indicating the nests of bees, and of guiding men to them by their motions and cries; whence both their scientific name and common appellation of honey guides.

INDICA'TOR. A muscle of the lower part of the fore-arm which extends the fore finger.

INDICA'VIT. (Lat. *he has shown.*) In Law, a species of the writ of prohibition. It lies for a patron of a church, whose incumbent is sued in the spiritual court by another clergyman for tithes amounting to a fourth part of the profits of the advowson; and depends on stats. West. 2. c. 5., 13 Ed. I. st. 4.

INDI'CTION. (Lat. indictio, *establishment*, *order*, or *denunciation.*) In Chronology, a cycle or period of fifteen years, the origin of which is involved in obscurity. Unlike other cycles, the indiction has no reference to any astronomical phenomena; but is supposed to relate to certain judicial acts, probably the publication of tariffs of the taxes, which took place at stated intervals under the Greek emperors. The Cæsarean indiction fell on the 8th of the calends of October (24th of September); the indiction of Constantinople (beginning A. D. 312) on the the 1st of September); the pontifical indiction on the calends of January. It is a date commonly employed in very ancient charters. The commencement of this computation is generally referred to the 1st of January of the year 313 of the common era; hence, by counting backwards, it will be found that the first year of our era corresponded to the fourth of one of the cycles of indiction. The year of indiction, corresponding to any other year of our era is found therefore by this rule:— Add 3 to the date, divide the sum by 15, and the remainder is the year of the indiction. The remainder 0 indicates the 15th of the cycle. Thus the year 1800 was the third of the indiction. See as to the historical commencement of the era of indictions, *Gibbon's Decline and Fall*, ii. 223. last ed. *Mem. de l'Acad. des Inscr.* vol. xli.

INDI'CTMENT, PROCESS BY. (Lat. indico, *I proclaim against.*) In Law, all persons, without exception, are liable to be arrested on a warrant of a justice of peace, if charged on suspicion with a crime; and some officers, as the sheriff or constable, have the power of apprehending without a warrant on some occasions. When the party is arrested and brought before a justice of peace, he is examined, and the information of those who came with him is taken; and the depositions of the witnesses, if taken down in the presence of the prisoner, are evidence against him on the trial. If the offence be bailable, the justice must then take sufficient bail on the part of the prisoner. If otherwise, he commits him to prison; and the witnesses are bound over to attend and give evidence, the king being in all cases the nominal prosecutor. The grand jury being summoned by the sheriff (at every session of the peace, commission of oyer and terminer and gaol delivery), consisting of not fewer than twelve nor more than twenty-three of the principal men of the county, receives the *indictment* or *presentment* (as it is also termed) preferred against the prisoner, and either *finds* or *ignores* it; returning it into court, in the first case, indorsed a *true bill;* in the latter, *not found.*

An indictment may be found in the absence of the prisoner; but cannot be tried unless he personally appears. The summons, when he is absent, in order to bring him into court, is by *capias;* and if he still abscond, he may be further pursued to outlawry. When the prisoner appears on this process, or voluntarily, or is brought up in custody, he is *arraigned;* that is, called before the bar to answer the indictment. If the prisoner refuse to answer (in which event he was subjected, in former days, to the famous *peine forte et dure*, by which it was intended to torture him into pleading, in order that the forfeiture of his goods might attach), a plea of not guilty is now recorded, and the trial proceeds; if he plead guilty, judgment is awarded. Otherwise he may plead — 1. To the jurisdiction; *i. e.* that the court before which he is arraigned is not competent to try the offence. 2. In abatement for misnomer; but the advantage of this plea is now taken away by 7 G. 4. 3. He may demur to the sufficiency in law of parts of the indictment. 4. He may plead one of the four special pleas in bar (former acquittal, former conviction, former attainder, and pardon). 5. He may plead not guilty of the crime alleged. If the prisoner plead not guilty, the fact of his guilt is forthwith tried on examination of witnesses by the petty jury. The nobility, it must be observed, are tried by their peers for treason or felony, and misprision of these crimes; but in other cases by a jury. The jurors are taken by the panel or list returned by the sheriff; and *criminal offences* are tried by the same common jurymen who try the issue of facts in civil cases in which a *special* jury has not been demanded. (*See* JURY.) The rules of evidence observed on the trial are mostly the same with those which prevail in civil actions. (*See* EVIDENCE.) One testimony, however, peculiar to this branch of law, is that of an accomplice; but it is considered essential that his testimony should be confirmed by other evidence. The verdict of the jury must in all cases be unanimous. After trial and conviction follows judgment, unless arrested by motion for that purpose, which it still may be on some exceptions to the indictment in point of law. Benefit of clergy, as it was termed, was usually prayed after conviction; and was held, in cases where not abolished by statute, to discharge the claimant from the capital part of the punishment. But this ancient privilege, which had long been founded on a mere fiction of law, was abolished by 7. G. 4. c. 36. Forfeiture of real property, absolutely, is a consequence of judgment in cases of high treason. The forfeiture of goods and chattels relates to, that is, takes effect upon, conviction; but fraudulent conveyances without consideration, in order to escape the forfeiture by the transfer of the property after or in contemplation of indictment, are void as against the king. The sentence of punishment pronounced or recorded on judgment is in some cases fixed and stated, so that the judges cannot modify the statutory penalty; in others (as in all offences at common law unregulated by statute), it is wholly or partly discretionary.

A criminal judgment may be reversed by writ of error for notorious mistakes and irregularities. A reprieve suspends the execution of a judgment: a pardon avoids the judgment altogether; and a pardon may be conditional on the prisoner's submitting to a substituted punishment, which is the ordinary mode of mitigating the severity of the law in capital felonies.

INDIGE'STION. *See* DYSPEPSIA.

INDI'GETES. The title of a class of Latin divinities, concerning the exact import of which there is some dispute; but it is probably most correctly referred to deified heroes, who became tutelary deities after death, according to the ancient mythology — as Romulus. The word is of very doubtful etymology.

I'NDIGO. A blue substance much used as a dye-stuff. The best indigo is obtained from an Asiatic and American plant, the *Indigofera*. The plant is bruised and fermented in vats of water, during which it deposits indigo in the form of a blue powder, which is collected and dried, so as to form the cubic cakes in which it usually occurs in commerce. Indigo is quite insoluble in water; when heated it yields a purple vapour, which condenses in the form of deep blue or purple acicular crystals. When indigo is exposed to the action of certain deoxidizing agents, it becomes soluble in alkaline solutions, losing its blue colour and forming a green solution, from which it is precipitated by the acids *white;* but it instantly becomes blue by exposure to air. This *white indigo* has been termed *indigogene*, and indigo appears to be its oxide. It is best obtained by mixing 3 parts of finely powdered and pure indigo with 4 of green vitriol, 5 of slaked quicklime, and 100 of water, repeatedly shaking the mixture. In about twenty-four hours the supernatant liquor, which is transparent, and of a green colour, is to be decanted off, and poured into dilute muriatic acid, when the deoxidized indigo is thrown down; but in order to prevent its absorbing oxygen and becoming blue, it must be most carefully excluded from the contact of air, which may be effected by syphoning it off into the acid, collecting it in vessels filled with hydrogen, and washing it with water deprived of air and holding in solution a little sulphate of ammonia. In this white state indigogene absorbs between 11 and 12 per cent. of oxygen to become blue indigo. It would appear from Dumas' experiments that indigogene is a compound of

	Atoms.		Equivalents.
Carbon - - -	45	=	270
Hydrogen - -	15	=	15
Nitrogen - - -	3	=	42
Oxygen - -	4	=	32
	1		359

and that indigo consists of 1 atom of indigogene = 359,

and 2 of oxygen = 16. The chemical equivalent of indigo, therefore, is 375.

When indigo is dissolved in concentrated sulphuric acid, it forms a deep blue liquid, known to the dyers by the name of *Saxon blue*. The great mart for indigo is Bengal, and he other provinces subject to the presidency of that name, from the 20th to the 30th deg. of N. lat.; but it is also cultivated, though not nearly to the same extent, in the province of Tinnevelly, under the Madras government in Java; in Luconia, the chief of the Philippine Islands; and in Guatemala and the Caraccas in central America. The following remarks, from the *Commercial Dictionary*, will exhibit the history of this now indispensable commodity, and the difficulties with which it had to contend before it obtained a permanent footing in the commerce of Europe. "It appears pretty certain that the culture of the indigo plant, and the preparation of the drug, have been practised in India from a very remote epoch. It has been questioned, indeed, whether the *indicum* mentioned by Pliny (*Hist. Nat.* lib. xxxv. c. 6.) was indigo; but, as it would seem, without any good reason. Pliny states that it was brought from India; that when diluted it produced an admirable mixture of blue and purple colours (*in diluendo misturam purpuræ cæruleique mirabilem reddit*); and he gives tests by which the genuine drug might be discriminated with sufficient precision. It is true that Pliny is egregiously mistaken as to the mode in which the drug was produced; but there are many examples in modern as well as ancient times to prove that the possession of an article brought from a distance implies no accurate knowledge of its nature, or of the processes followed in its manufacture. Beckmann (*Hist. of Inventions*, vol. iv. art. "Indigo") and Dr. Bancroft (*Permanent Colours*, vol. i. pp. 241—252.) have each investigated this subject with great learning and sagacity; and agree in the conclusion that the *indicum* of Pliny was real indigo, and not, as has been supposed, a drug prepared from the *isatis* or woad. At all events, there can be no question that indigo was imported into modern Europe, by way of Alexandria, previously to the discovery of the route to India by the Cape of Good Hope. When first introduced, it was customary to mix a little of it with woad to heighten and improve the colour of the latter; but, by degrees, the quantity of indigo was increased; and woad was, at last, entirely superseded. It is worth while, however, to remark, that indigo did not make its way into general use without encountering much opposition. The *growers of woad* prevailed on several governments to prohibit the use of indigo! In Germany, an imperial edict was published in 1654, prohibiting the use of indigo, or '*devil's dye*,' and directing great care to be taken to prevent its clandestine importation; 'because,' says the edict, 'the trade in woad is lessened, dyed articles injured, and money carried out of the country!' The magistrates of Nuremburg went further, and compelled the dyers of that city to take an oath once a year not to use indigo; which practice was continued down to a late period. In 1598, upon an urgent representation of the states of Languedoc, at the solicitation of the woad growers, the use of indigo was prohibited in that province; and it was not till 1737, that the dyers of France were left at liberty to dye with such articles, and in such a way, as they pleased." (*Beckmann*, vol. iv. p. 142.)

INDI′GOLITE. Blue *tourmalin*.

INDIGO′TIC A′CID. An acid obtained by boiling indigo in nitric acid diluted with an equal weight of water. It forms white crystals, very soluble in hot water, but very sparingly soluble in cold water. It consists, in the 100 parts, of 48·23 carbon, 2·76 hydrogen, 7·73 nitrogen, and 41·28 oxygen; or, according to Dumas, of 1 atom of indigogene = 359, and 30 atoms of oxygen = 240.

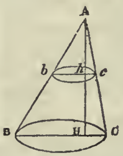
INDIVI′DUAL. (Lat. individuus.) In the Fine Arts, that which is proper or peculiar to a single object of a species.

INDIVI′SIBLES. Infinitely small quantities which admit of no further division.

In Algebra, the *method of indivisibles* is the name given to a peculiar species of calculus, invented by Cavalieri, a disciple of Galileo, and much used by mathematicians before the invention of the method of fluxions, or the differential and integral calculus; for which it prepared the way, and of which to a certain extent it supplied the place.

In the method of indivisibles lines are considered as composed of an infinite number of points, surfaces as composed of an infinite number of lines, and solids of an infinite number of surfaces. These hypotheses are no doubt inconsistent with the rigorous exactness of the ancient geometry, and, taken in the strict sense of the terms, absurd; for lines, however they may be multiplied, can never compose a surface, or any thing else than linear magnitude; nor can surfaces, however they may be added together, compose a solid, or any thing but an area. Nevertheless, inaccurate as these ideas are, the conclusions deduced from them are strictly correct; and they afford, in numerous cases, a means of obtaining readily and easily what could only be found by a very long and troublesome process in following the ancient and rigorous method of exhaustions. In fact, the objections apply rather to the manner in which the hypotheses are stated than to the method itself, which, in reality, is merely a formula of abbreviation, extremely useful as a means of avoiding the tediousness of the method of exhaustion without diminishing in any way the accuracy of the results. Its purpose is to give at once the result of an infinite series of successive approximations; and, as is remarked by Professor Playfair, nothing perhaps more ingenious, and certainly nothing more happy, ever was contrived, than to arrive at the conclusion of all these approximations without going through the approximations themselves.

As an example, — Let it be proposed to determine the volume of a cone. From A, the vertex of the cone, let a perpendicular A H be drawn to its base. Conceive this perpendicular to be divided into an infinite number of equal parts, and through each of the points of division a plane to pass parallel to the base of the cone; according to the principles of the method of indivisibles, each of these planes, as $b\,c$, limited by its intersection with the surface of the cone, will be one of the elements of the volume of the cone, and the whole volume will be the sum of all these elements.



Now, by the properties of the cone these elements are to each other as the squares of their distances from the vertex; therefore, taking A to represent the area of the base of the cone B C, a the area of the plane $b\,c$, H the height A H, and h the height A h, we have $A : a :: H^2 : h^2$; whence $a = \frac{A}{H^2} h^2$. Now, if we make V = the sum of these elements, or the volume of the cone, it is evident that we have V equal to the constant $\frac{A}{H^2}$ multiplied by the sum of the squares h^2. But the distances h increase as the series of natural numbers from nothing to H; consequently the quantities h^2 represent the squares of those numbers from 0 to H^2. Now it is known that the sum of the squares of the natural numbers, from 0 to H^2 inclusive, is

$$\frac{2\,H^3 + 3\,H^2 + H}{6};$$

but in the present case the number H being supposed infinite, all the terms in the numerator after the first will be infinitely small in comparison of the first, and ought therefore to be rejected; whence the sum of all these squares is reduced to $\frac{1}{3}H^3$. Multiply, therefore, this value by the constant $\frac{A}{H^2}$ found above, we have for the volume of the cone $V = \frac{1}{3}A\,H$; that is to say, the volume of the cone is equal to the product of its base by a third of its altitude.

In a smilar manner the areas of innumerable curves, and the cubature of many solids, are found without difficulty. It was in this way that Torricelli, or Roberval, found the quadrature of the cycloid, — a problem of great celebrity among the early mathematicians. The work of Cavalieri, *Geometria Indivisibilibus continuorum nova quadam ratione promota*, was published at Bologna in 1653; but he had treated of the subject in a previous work, *Exercitationes Geometricæ Sex*, published in 1647.

INDU′CEMENT. In Law, a term used specially in various cases to signify a statement of facts alleged by way of previous explanation or introduction to other material facts. Averments which are mere inducement need not be proved so precisely as others.

INDU′CTION (Lat. *in*, and duco, *I lead*), the counter-process in scientific method to deduction, implies the raising individuals into generals, and those into still higher generalities; deduction being the *bringing down* of universals to lower genera or to individuals. Every deduction, therefore, to be valid, must rest on a prior induction, which, in order that we may obtain logical certainty, must be a *complete* induction; that is to say, must include *all* the individuals which constitute the genus. This, it is evident, is impossible, so long as we assume the only power necessary to induction to be the observation of particulars; for these are infinite in number: we can never be sure that we have observed them all. We are therefore compelled, if we are to admit the possibility of science properly so called, to allow the necessity of some spontaneous action of the understanding in every inductive process; of a faculty, in short, which takes occasion from experience to arrive at the knowledge of truths not contained in that experience. Philosophers differ widely in the language under which they convey their belief of this truth. Had the thing itself, however, been more distinctly borne in mind, we should have been saved much useless obscurity; in particular, we should

have escaped that altogether futile distinction made by logicians between "perfect and imperfect induction." All the certainty that can be obtained in physics is a hypothetical certainty, founded on our belief that the course of nature is uniform; but as regards the form of our reasoning, which is all that the logician contemplates, that remains the same whether the certainty be real or assumed. (See for valuable accounts of the Baconian system of induction, *Playfair's Introductory Essay to the Enc. Brit.*; and *Hallam on the Literature of Europe*, vol. iii.)

INDU'CTION. In Electricity, when one electrified substance is opposed to another, the latter acquires, under certain circumstances, an opposite electric state upon the surface opposed to the inducing body, and is rendered electro-polar. *See* ELECTRICITY.

INDU'LGENCE. (Lat.) A power claimed by the Roman Catholic church of granting to its contrite members remission for a certain term, either on earth or in purgatory, of the penalty incurred by their transgressions. The practice was first instituted in the eleventh century by Popes Gregory VII., Victor, and Urban II., as a recompence to those who embarked in the perilous enterprise of the Crusades; but its benefits in process of time extended to all who, either by donations or other services, contributed to the wellbeing of the church. It was the profligate sale of indulgences that first excited Luther to commence his warfare against the see of Rome; and although the traffic in indulgences has been reprobated by many councils, and some minor corruptions have been partially reformed, still the Council of Trent decreed the usefulness and validity of such instruments, and left the whole control of their nature and manner of issuing them entirely in the discretion of the pope for the time being. (For an elaborate exposition of this subject, see the *Bibliothèque Sacrée*, article "Indulgence;" also *Mosheim*, iii. 83. translation.)

INDUME'NTUM. (Lat. induo, *I put on.*) In Zoology, the term is restricted in its signification to the plumage of birds. This consists of the peculiar epidermic organs called feathers and down, with sometimes a scanty admixture of hair. (The description of the component parts of plumage is given under the head of FEATHERS.) The plumage is generally more than once changed before it attains that state which is characteristic of the fully mature bird. The period during which these mutations are proceeding varies from one to five years, and many birds rear a progeny before they acquire the plumage of maturity. When the indumentum of the male bird differs in colour from that of the female, the young birds of both sexes resemble the latter in their first plumage; but when both the adult male and female are of the same colour, the young have then a plumage peculiar to themselves. In some species the adult birds have a plumage during the breeding season decidedly different in colour from that which they bear in winter: in these cases the young birds differ in colour from both parents, and have a plumage which is intermediate in its general tone to that of the two periodical states of the parent birds, and bearing indications of the colours to be afterwards attained at either period.

The changes in the colour of the plumage of birds are effected either by a total moult of the old and acquisition of new feathers; or by a partial moult, and the admixture of new feathers with a certain proportion of the previous plumage; or on the bird's obtaining a certain number of new feathers without shedding any of the old ones; or, lastly, by the fully formed feather itself becoming altered in colour: the last two changes take place in the adult birds at the approach of the breeding season. The change of colour of a fully developed feather is produced either mechanically by the wearing away of the lighter coloured tips, which exposes the brighter tints of the plumage beneath, or by some internal chemical or vital influence upon the colouring matter of the feather itself: the latter change begins at that part of the web nearest the body of the bird, and gradually extends outwards till it pervades the whole feather.

INDU'SIAL LIMESTONE. A fresh-water limestone found in Auvergne, abounding in the indusiæ or cases of the larvæ of *Phrygania*, great heaps of which have been encrusted by hard travertin and formed into rock.

INDU'SIUM. (Lat. induo.) A cup that surrounds the stigma of Goodeniaceous and some other plants; it is also the name of the membrane that covers the thecæ in Dorsiferous ferns.

INDU'VIÆ. (Lat.) The withered remains of leaves that not being articulated with the stem cannot fall off; the part covered by them is said to be *induviate*.

INEQUA'LITY, in Astronomy, is applied to any deviation in the motion of a planet or satellite from its uniform mean motion.

INE'RTES. (Lat. iners, *slothful.*) The name of an order of birds in the ornithological system of Temminck, including the *dodo* and *apteryx*.

INE'RTIA. (Lat. iners.) This term is used to denote the principle or law of the material world that all bodies are absolutely passive or indifferent to a state of rest or motion, and would continue for ever at rest, or persevere in the same uniform and rectilinear motion, unless disturbed by the action of some extrinsic force. The ancients attributed to matter a certain inaptitude, reluctance, or renitency to motion; but that a body in motion required the operation of an extrinsic cause to bring it to rest was first discovered by Galileo. Kepler, conceiving the disposition of a body to maintain its motion as indicating an exertion of power, prefixed the word *vis*; and the compound expression, *vis inertia*, though less accurate, has been generally retained. Inertia is one of the inherent properties of matter, and unceasingly recalled to our observation in every incident of life.

INESCU'TCHEON. In Heraldry, a species of ordinary, being an escutcheon placed upon the fess point (*see* FESS); and containing, it is said, the third part when charged, the fifth when otherwise. All escutcheons borne within escutcheons are by some heralds called by this name.

IN ESSE. (Lat.) A term applied to things actually existing. A difference is made by authors between *in esse* and *in posse*: the latter being applied to things that are not, but may be; the former being said of things actually apparent and visible.

I'NFANT. In Law, a person under twenty-one years of age. He is not considered in law as having sufficient ability to contract, and is protected from his own improvidence and the artifices of designing persons by his not being liable for any engagements into which he may have entered, except for necessaries suited to his condition in life. His contracts, however, are not absolutely void, but only voidable; and though they cannot be enforced against him, yet he may, if he do not choose to avoid them, enforce them against another, and may always confirm them on the termination of his minority. He is in general responsible in damages for torts committed by him, as for slander or assault. His responsibility for crimes varies according to his age and discretion: under seven years of age he cannot be guilty of felony; between seven and fourteen a presumption arises that he is doli incapax; but this presumption may be repelled by proof that he could plainly distinguish between good and evil, and he may then suffer death as a felon; and after fourteen he is in general as amenable to punishment as a person of full age.

His disabilities, many of which are in the nature of privileges, and established for his protection, are numerous: he cannot fill any office connected with the administration of justice, or sit in parliament; he cannot be an executor, nor appear in court by attorney. The consent of parents or guardians, or of the Court of Chancery, is requisite to his marriage.

I'NFANTE, INFANTA. The titles borne by the younger sons and the daughters of a king of Spain, the eldest son being styled Prince of Asturias. It is found in a document of the year 999, applied to the sons of King Veremond II. It appears, however, to have been anciently given to all hidalgos. (*Quart. Rev.* vol. lxii. p. 104., where the reader is referred to the Ley de Partidas, 1, 2.) The word "childe" was similarly used in England in the middle ages.

INFA'NTICIDE, or CHILD-MURDER, by the law of England is placed upon the same footing with other homicide. By 9 G. 4. c. 41. s. 14. a woman indicted for murder of her child may, if acquitted of the murder, be convicted of the misdemeanour of secreting the body of the child to conceal its birth. To administer poison, or use other means to procure the miscarriage of a woman great with child, is a capital felony by the same statute (c. 14.). The exposure of new-born infants, especially females, is a common practice among many savage nations at the present day, and especially prevalent among the Chinese. According to Lord Macartney, the number of infanticides committed in Pekin alone exceeds 20,000 a year; but it is to be hoped that this calculation is highly exaggerated.

I'NFANTRY. The general name for soldiers who serve on foot. The term is in all probability derived from the Italian word *fante*, signifying a child or young person; and was originally conferred on the young Italian peasantry, who served in the wars on foot, the nobles being usually mounted. There are, however, various other accounts of the origin of the term. Among the ancient Greeks and Romans, the infantry constituted the chief strength of an army; and, with the exception of that period in European history during which the institutions of chivalry prevailed, when the tournament with its gay appendages engaged the attention of all the powerful nobles and otherwise distinguished persons, who thus imparted to the *cavalry* a factitious importance, it has generally been regarded as the principal military arm. Since the institution of standing armies this has been peculiarly the case. From the period of the Conquest down to the reign of Henry VIII., the infantry of

this country consisted of the inferior vassals of the feudal tenants, and from the cause above referred to was neglected both in discipline and accoutrements; but the connection of that monarch with Charles V. of Germany and Francis I. of France, whose rivalry in arms had introduced great improvements into this arm, was the means of directing attention to the defects of the English infantry, and paved the way for the introduction of that system of discipline which after the lapse of three centuries has now brought it to perfection. The British army comprises, exclusively of the militia, artillery, engineers, and marines, 99 regiments of regular infantry, three regiments of foot guards; besides a rifle brigade, two West India regiments, and the Ceylon rifle regiment. *See* ARMY, and the authorities there referred to.

INFE'CTION. *See* CONTAGION.

INFE'RIÆ. (Lat.) Sacrifices offered by the Greeks and Romans to the Dii Manes, or the souls of deceased heroes, or any person whose memory was held in veneration. These sacrifices consisted of almost every kind of offering, and were instituted on the ninth and thirtieth days after interment. They are supposed by some writers to have been the origin of the exequies (quod vide) of the Roman Catholic church.

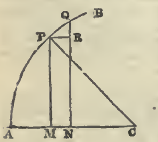
INFE'RIOR. A term given to a calyx that is distinct from the ovarium, as in *silene;* or to an ovary that adheres to the calyx, as in the myrtle. It is a bad expression, though commonly employed, for which the French school have substituted the words nonadherent and adherent.

I'NFERO-BRANCHIA'TA. (Lat. inferus, *lower;* Gr. *βραγχια, gills.*) An order of Gastropods, characterized by the position of the gills, which are situated beneath the produced margin of the mantle; they consist of two long series of leaf-shaped vascular organs. This order comprehends, in the system of Cuvier, two genera, *Phyllidia* and *Diphyllidia.*

I'NFIDEL. (Lat.) A term applied to such persons as are not baptized, or do not believe in the Christian religion. *See* DEIST.

I'NFINITE. (Lat. infinitus, *boundless.*) In Geometry, an infinite quantity is properly that which is greater than any assignable magnitude; and as no such quantities exist in nature, it follows that an infinite quantity is merely an abstraction of the mind, formed by excluding the idea of limit or boundary. An *infinitely small quantity* is a quantity considered as less than any assignable magnitude. There is, however, a peculiar signification attached to this expression in mathematical language, which has frequently been misunderstood. Infinitely small quantities are not absolute zeros, or even quantities actually less than certain determinate magnitudes; they are merely quantities which the conditions of the proposed question permit to be regarded as variable until the calculation is entirely completed, and as diminishing continually until they become as small as we please, without its being necessary to change the values of those quantities of which the relation is sought. It is in this circumstance only that the peculiar character of what are called infinitely small quantities consists, and not in the *littleness* which their denomination seems to imply, or in the absolute nullity which may be attributed to them.

INFINITE'SIMAL. In Geometry and Analysis, an infinitely small quantity; that is to say, a quantity which is less than any assignable magnitude. The *infinitesimal analysis* is the art of employing infinitesimal quantities as auxiliaries, in order to discover the relations which exist among the proposed quantities. It differs from the differential calculus, or the method of fluxions, only in respect of its metaphysical principles; the analytical processes are precisely the same in both. In the theory of infinitesimals, a curve is regarded as a polygon of an infinite number of sides, any one of which represents the arc. Thus, let P Q be one of those sides; then P Q is the hypothenuse of a right-angled triangle, of which the sides P R and R Q are the differentials of the co-ordinates A M and M P, or of x and y. Hence, making P Q $= dz$, we have $dz^2 = dx^2 + dy^2$. On the same principle, if s denote the infinitely small element of the area, or the space M P Q N, we shall have $ds = ydx + \frac{1}{2}\,dy\,dx$ (for M P Q N $=$ M P R N $+$ P Q R $=$ M P $\cdot$ M N $+ \frac{1}{2}$ Q R $\cdot$ P R). But the second part of this expression, namely, $\frac{1}{2}\,dy\,dx$, is an infinitesimal of the *second order*, being the product of two infinitely small quantities, and therefore infinitely smaller than $y\,dx$, which is an infinitesimal of the first order. The part $\frac{1}{2}\,dy\,dx$ must therefore be omitted, being of no value in comparison of the quantity to which it is added and we have consequently $ds = y\,dx$. The elemental triangle P Q R also shows at once the differential values of the trigonometrical lines. Thus, supposing the curve A B to be a circle whose centre is C, then the radius C P being unity, and the arc A P being denoted by z, we have 1 : cos. z : : P Q : Q R : : dz : d sin. z; whence d sin. $z =$ cos. $z\,dz$. Again, 1 : sin. z : : P Q : P R : : dz : $-\,d$ cos. z; therefore d cos. $z = -$ sin. $z\,dz$.



The theory of infinitesimals affords very great facilities in the application of the calculus to the higher geometry, and especially in the doctrines of physics. Whatever view may be taken of the principles, the results, if deduced by correct reasoning, are rigorously accurate; and the mathematician will scarcely be restrained by metaphysical considerations from attempting to reach his object in the shortest way, which, in very numerous applications of the calculus, is by the infinitesimal method.

INFI'NITIVE MOOD. In Grammar, that inflexion of the verb which expresses the conception merely, without affirming or denying it, of any subject. *See* GRAMMAR.

INFI'NITY. *See* INFINITE.

INFI'RMARY. (Lat. infirmus, *weak.*) An hospital for the reception of the sick poor, either supported by the public, or endowed by benevolent persons with funds to defray the necessary expense. Establishments bearing this name are not uncommon in all considerable towns of the British empire. *See* HOSPITAL.

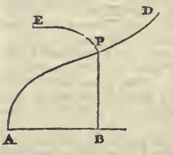
INFLAMMA'TION. In Pathology, this term is applied to redness and heat of some part of the body, attended by pain and swelling: the vascular action of the part is increased; and if it does not subside or terminate in *resolution*, it produces three different effects, which, where they take place healthily, follow each other in regular order. These are, 1. adhesion; 2. suppuration; 3. ulceration.

I'NFLEXED. (Lat. inflecto, *I bend.*) In Zoology, when a part is bent inwards.

INFLE'XION, in Grammar, in strictness of language, is any change which takes place in a word from a modification of its sense between the *root* and the *termination.* The inflexion must therefore not be confounded with the termination itself. Thus the syllable *am* is the root of all the words employed in the conjugation of the Latin verb amo, *I love;* in the imperfect tense, the inflexion is the syllable *ab*. The termination varies according to the person; amabam, amabas, amabat.

INFLE'XION. In Optics, the same as *diffraction;* or that property of light by reason of which, when it passes very near the borders of an opaque body, it is turned from its rectilinear course. *See* DIFFRACTION and LIGHT.

Point of inflexion, in Geometry, is that point of a curve line where the curvature in relation to the axis changes from concave to convex, or from convex to concave. The same point is also called the point of *contrary flexure;* and if the direction changes suddenly with relation to the ordinate as well as the absciss, the point becomes a *point of regression.* Thus, let A P be a curve which from A to P is concave towards the axis A B, and from P to D convex towards the axis; the point P, at which it passes from concave to convex, is the *point of inflexion;* and if the curve at P is turned backwards as P E, the P is the point of regression. The determination of these points is attended with no difficulty, and the method of determining them will be obvious from the following considerations. When a curve is concave to the axis, the differential of the ordinate (that of the absciss being supposed constant) decreases; consequently the second differential, or $d^2\,y$, is negative. On the contrary, when the curve is convex to the axis, dy increases, and d^2y is positive. At the point, therefore, at which the curvature changes from concave to convex, d^2y changes its sign; but as no variable quantity can change its sign without becoming nothing or infinite in relation to its former magnitude, it follows that at the point of inflexion, or regression, $d^2y = 0$ or infinity. Hence to find the point of inflexion in any given curve, it is only necessary to find from the equation of the curve the value of $\frac{d^2y}{dx^2}$; this value, made equal to 0 or infinity, will give an equation by which x is determined. This subject is treated at length in the work of Cramer, *Sur les Lignes Courbes;* also in Lacroix's *Calcul Differentiel et Integral;* and noticed in almost every work on the Differential Calculus.



INFLORE'SCENCE. (Lat. inflorescere, *to flourish.*) The general arrangement of the flowers upon a stem or branch. It consists of the following principal kinds: viz. the spike, the raceme, the panicle, the capitulum, the umbel, and the cyme; each of which is mentioned in its place.

INFLUE'NZA. (As if produced by the influence of the stars.) An epidemic *catarrh*, generally attended by languor, headach, quick pulse, and febrile symptoms, which often run very high, and assume a variety of aspects, dependent upon the season and other causes. The possibility of the existence of some highly poisonous and irritating vapour, though in very minute quantity, as the exciting cause of influenza, has been suggested by Dr. Prout. It may possibly be of volcanic origin; and such a

substance as selenluretted hydrogen, the effects of which, even in extremely minute quantity, are highly deleterious, might perhaps account for some of the phenomena of this extraordinary disease.

IN FO'RMA PAU'PERIS. In Law, a person is said to sue as a pauper, or *in forma pauperis*, when he takes advantage of the stat. 11 H. 7. c. 12., swearing himself not to be worth five pounds; in which case he is entitled to have original writs and subpœnas gratis, and attorney and counsel assigned him without fee, and is excused from paying costs when plaintiff. By misconduct, and under certain other circumstances. the party is dispaupered, and loses his privilege. He is capable of recovering costs, although not liable.

INFORMA'TION. In Law, an accusation exhibited against a defendant for some criminal offence; not on the oath of jurors, but on the special allegation of an officer empowered to exhibit it. Criminal informations are either partly at the suit of the king and partly at that of a subject, namely, such as are brought upon certain penal statutes at the suit of common informers; or wholly at the suit of the king. These are of two sorts: 1. those filed ex officio by the attorney-general, which is a proceeding resorted to in the case of some particular misdemeanours of a public nature, as libels and various other offences concerning the public government; and 2. informations filed at the suit of the master of the crown office, which lie for some gross and notorious misdemeanours, as riots, batteries, libels, &c., not immediately tending to disturb the government.

INFO'RMED STARS (Informes Stellæ), in Astronomy, are stars not included in any of the constellations. *See* CONSTELLATION.

I'NFRALAPSA'RIANS. In Ecclesiastical History, a sect of Presbyterians who maintain that God has created a certain number of human beings only to be damned, without allowing them the opportunity of salvation even if they chose to embrace it. They are thus designated because they hold that the decrees of God were formed *infra lapsum*, after his knowledge of the fall, and in consequence of it. *See* SUPRALAPSARIANS.

INFUSO'RIA. (Lat. infundo, *I pour in.*) A name applied by Otho Fr. Müller to an assemblage of microscopic animalcules which are for the most part developed in infusions of decayed animal and vegetable substances. Some of these minute organized beings were known to Linnæus, and were placed by him at the end of the class *Vermes*, in a genus which he denominated *Chaos*. Müller, who made the Infusoria a subject of special study, discovered numerous distinct genera and species, which he named and classified according to their outward form. Gmelin and Lamarck introduced Müller's discoveries and classification of the Infusoria into their systems without any particular modification. Cuvier, in 1829, observes, that "Naturalists usually close the catalogue of the animal kingdom with beings so extremely minute as to be invisible to the naked eye, and which have been discovered only since the invention of the microscope has unveiled to us, as it were, a new world. Most of them present a gelatinous body of the greatest simplicity, and for these this is undoubtedly the situation; but authors have placed among the Infusoria animals apparently much more complicated, and which only resemble them in their minuteness and the dwelling in which they are usually found." These higher-organized Infusoria were placed by Cuvier at the head of the class in a distinct order, under the name of *Rotiferes* or *Rotifera*, a name which has subsequently been retained. Cuvier attributes to these animalcules a mouth, a stomach, an intestine, and an anus; and notices the prominences on the anterior part of the body, which some observers had regarded as eyes. The anterior lobated organ and its vibratory denticulations, the successive action of which gives to the organ the appearance of a swiftly rotating wheel, forms the main external character of the order. Cuvier includes in the order *Rotatoria* the genera *Furcularia*, Lam.; *Vaginicola*, Lam.; *Tubicolaria*, Lam.; *Brachionus*, Müller.

The investigations of Ehrenberg, with the aid of a superior microscope to that of his predecessors, have brought to light many additional organs and complexities of structure in the *Rotifera*, besides several genera and species before unknown; and since these researches naturalists have generally regarded the *Rotifera* as a distinct class of Invertebrata, which Professor Grant has placed in the Articulate sub-kingdom, and Professor Owen in the *Nematoneura*, or higher division of Cuvier's Radiata. For the character, subdivision, and organization of the *Rotifera*, see that word.

The second order of Infusoria in Cuvier's system is denominated *Homogenea*; a term sufficiently expressive of the inadequate ideas current at that recent period respecting their organization. Cuvier says, "The body of the *Homogenea* presents neither viscera nor other complication, and is frequently destitute of even the appearance of a mouth." Ehrenberg has since shown that they have not only really a mouth, but that the greater part of the *Homogenea* of Cuvier possess a digestive cavity complicated with many cæcal pouches or stomachs; and accordingly proposes to name the order *Polygastrica*. Cuvier includes in his second order of Infusoria the genera *Urceolaria*, Lam.; *Trichoda*, *Leucophra*, *Kerona*, *Himantopus*, *Cercaria*, *Furcocerca*, *Vibrio*, *Proteus*, *Volvox*, and *Monas*. As the polygastric structure has not been detected in any species of *Cercaria*, but as, on the contrary, some species, as *Cercaria lemnæ*, possess a simple alimentary canal, this genus, together with the cercarial *Spermatozoa*, and the *Vibrionidæ*, which all possess a straight and simple alimentary canal, have been removed from the Infusoria, and classed by Mr. Owen with the Entozoa.

Thus the animals of infusions, although of comparatively simple organization, possessing neither a heart nor respiratory organs, yet manifest at least three distinct types of structure, and are referable to three different classes of animals.

Many genera of Infusoria are protected by an external siliceous case. The observations which Ehrenberg had made on the modifications of the form and surface of these cases of the existing Infusoria led to his capital discovery of their remains in a fossilized state. The mineral called *Polir-scheifer*, used for a long period in the arts for polishing metals and other substances, was first dicovered to be composed of myriads of the microscopic flinty cases of polygastric Infusoria belonging to the genera *Grilionclla*, *Bacillaria*, *Diatorna*, &c. Whole strata of considerable extent and thickness have since been found to consist almost exclusively of the fossil remains of Infusoria.

INGLU'VIES. (Lat. *a crop.*) The crop or dilatation of the œsophagus, in which the food is accumulated and macerated, but not digested. It is largest in the Gallinaceous birds and pigeons, but exists in certain birds of prey; also in the flamingo, and others.

I'NGOT. A word of doubtful origin, signifying chiefly the small masses or bars of gold and silver intended either for coining or exportation.

INGRO'SSING. *See* ENGROSSING, FORESTALLING.

INHA'BITANT. In Law, a word used in various technical senses. Thus a person having lands or tenements in his own possession is an inhabitant for the purpose of repair of bridges, wherever he may reside; but for purposes of personal services the "inhabitant" must necessarily be a resident. For the purpose of the poor rate, the word means a person residing permanently and sleeping in the parish. Where the right of voting is in "inhabitant" householders, a variety of divisions in committees of the House of Commons, in some instances conflicting, have taken place on the point. But it appears to be generally understood that an inhabitant is one who keeps a house in his own occupation, either personally residing in it, or having it occupied by servants and ready for his residence; having what is termed the "animus levertendi," or intention to return.

INHARMO'NICAL RELATION. In Music, that in which a dissonant sound is introduced.

INHE'RITANCE. In Law, an estate or real property which a man has to himself and his heirs, or the heirs of his body, &c., is termed a freehold of inheritance.

INHIBI'TION. (Lat. inhibeo, *I restrain.*) In Scottish Law, a species of diligence; *i. e.* process. It is a writ in the king's name, passing under the signet, whereby a debtor is prohibited from contracting any debt which may become a burden on his heritable property in competition with the creditor at whose instance the inhibition is taken out; and from granting any deed of alienation, &c., to the prejudice of the creditor. The heir of the debtor is not affected by the inhibition of his ancestor. Other species of inhibition are, that of a husband against his wife, intended to signify that her superintendence over domestic affairs has ceased, on which his liability for domestic expenditure contracted by her also ceases; and inhibition of tithes or teinds.

INHIBITION. In Ecclesiastical Law, a writ, commonly issuing out of a higher court Christian, to forbid an inferior judge from further proceeding in a cause before him; being analogous to a prohibition issuing out of one of the king's superior courts of justice.

INIS. An Irish word signifying island, used as a prefix to the names of some islands on the coast of Ireland, and of several towns situated on lakes or rivers in the same country; as Inisfallen, Iniskilling, &c.

INI'TIATIVE. (Lat. initium, *a beginning.*) In Politics. In legislative assemblies constituted so as to comprise more than one chamber, or more than one distinct and co-ordinate power, that branch of the legislature to which belongs of right the power to propose measures of a particular class is said to have the initiative with respect to those measures. Thus in England all propositions for taxing the subject, whether directly or indirectly, must begin in the Commons; a usage which has been adopted in most modern constitutions. On the other hand, there are some private bills which by custom originate in the Lords; and one bill, that, namely, for a

general pardon, is proposed in the first instance by the crown. In France, by the charter of 1830, the three branches of the constitution enjoy like privileges in proposing laws; but custom generally concedes the initiative to the Chamber of Peers, excepting in the case of money bills, which must, as in England, originate with the Chamber of Deputies.

INJU'NCTION, in Law, is a writ which issues under the seal of a court of equity. It is granted in various cases, where the court thinks fit to interfere on equitable grounds with the acts of parties, or with the course of other jurisdictions. Thus injunctions are granted under certain circumstances to stay proceedings at common law; to restrain the negotiation of notes and other securities; to restrain parties from the commission of waste; to preserve property which is in course of litigation, &c. Injunctions are also granted to direct parties to quit possession of lands, &c. after a decree. Disobedience to an injunction is punishable as a contempt of the court from which it issues.

INK. (Germ. dinte.) The colouring matter of common writing ink is the tannogallate of iron, which is suspended in water by gum arabic; a little logwood is generally added to deepen and improve the colour. A good writing ink is made as follows:—Take six ounces of finely bruised galls, four ounces of gum arabic, four ounces of green vitriol, and six pints of soft water. Boil the galls in the water; then add the other ingredients; and mixing the whole well together, keep it in a well-corked bottle, occasionally shaking it. In two months' time carefully pour off the ink from the residue into glass bottles, which should be well corked; a few cloves or a drop or two of creosote put into each bottle prevent moulding. The addition of a little sugar to ink gives it a gloss, and prevents its drying rapidly and perfectly; so that it is generally used in what is called *copying ink*, from the writing with which copies may be taken by pressure. *Indian ink* is a compound of very fine lampblack and size. It cannot, like common writing ink, be removed by acids; but as it does not bite or sink into the paper, it may generally be wiped off with a moist sponge. *Printing ink* is made with boiled linseed or nut oil and lampblack. *Red ink* is a solution of alum coloured with brazil wood. Boil two ounces of brazil wood, half an ounce of gum arabic, and a quarter of an ounce of alum in a pint of water for ten minutes; strain the decoction, and set it aside to clear. *Sympathetic inks* are compounds which when written with will remain invisible till heated: solutions of cobalt thus become blue or green, lemon juice turns brown, and a very dilute sulphuric acid blackens. *Marking ink* is made as follows: — Dissolve one drachm of lunar caustic (fused nitrate of silver) in half an ounce of water previously thickened with a little sap green: write with this upon the linen previously prepared for its reception by the application of a weak solution of carbonate of soda thickened with a little gum arabic, and suffered to dry upon the linen.

INLI'DANS, *Inlidæ*. The name of a family of Myriapods, having the inlus or gally-worm as the type.

I'NNOCENTS' DAY. In the Calendar, a festival celebrated on the 28th of December, in commemoration of the infants murdered by Herod.

INNO'MINATUM. (Lat. in, priv., and nomen, *a name; without a name.*) Each of the lower bones of the pelvis is called *os innominatum;* because the three bones of which it consists originally, namely, the *ischium*, the *ilium*, and the *pubis*, or the hip bone, the haunch bone, and the share bone, grow afterwards together so as to form what appears to be a single bone, which is thus left nameless.

INNS OF COURT. Four corporate societies established in London. Every candidate for the rank of barrister-at-law is obliged to be admitted a member of one of these societies, and submit to its regulations as a student. These are, — 1. the Inner Temple, to which three *Inns of Chancery* (Clifford's, Lyon's, and Clement's) belong; 2. the Middle Temple, with Strand Inn (no longer existing) and New Inn dependent on it; 3. Lincoln's Inn (with Furnival's and Thavie's Inns), Gray's Inn (with Staple's Inn and Bernard's Inn).

INNUE'NDO. (Lat. innuo, *I nod or beckon.*) In Law. In the old Latin forms of pleadings this term was used as a word of reference, when in relating the words of another party it was necessary to describe more particularly the person or thing meant by that party; as, for instance, in a declaration in action for slander, which is the most ordinary modern case of the employment of the innuendo, the plaintiff avers that the defendant said that "he," innuendo (meaning the plaintiff), was a thief, &c. Hence the use of the word "an innuendo" in ordinary language to signify a covert allusion.

INO'CULATION. The insertion of poisonous or infectious matter into any part of the body; but in this country the phrase is commonly used to signify the insertion of the virus of the common smallpox, the insertion of the virus of the cowpox being called *Vaccination*. Inoculation was introduced into general notice by Lady Mary Wortley Montague, whose son was inoculated at Constantinople about the year 1721, and whose daughter was the first who underwent the operation in this country. A milder disease is thus propagated than when it is received in the natural way. Inoculation is performed by inserting the point of a lancet armed with proper matter just under the cuticle, and afterwards gently rubbing the armed part over the pricked cuticle. *See* VACCINATION.

INO'CULATION OF GRASS LANDS. The ordinary method of turning a ploughed field into a meadow or pasture is by sowing it with grass seeds; but as this part of agriculture has hitherto been very ill understood, and the result of sowing grass seeds has frequently not answered the expectations of the sower, the practice of what is called *inoculation* has of late years been invented, though practised but in very few instances. This consists in preparing the soil as if it were to be sown down with grass seeds; but instead of sowing these on the surface, there are distributed over it small fragments of turf taken from the best old pasture land which the neighbourhood affords. These fragments may be about two or three inches square, and they are laid down on the surface at the rate of about one in every square foot. After they are deposited grass seeds mixed with clover are scattered over the surface, and the field is rolled to press down the the turf and press in the seeds. In consequence of the fragments of turf being placed on fresh soil, the grasses and other vegetables which they contain, if of the creeping kind, grow luxuriantly, and their stems cover the intervals between the fragments; but if the grasses which the fragments contain should not be of the creeping or stoloniferous kinds, it is evident that the intervals between them must chiefly depend for their grassy surface on the seeds which have been sown. On the whole, the inoculation of grass land may be considered as a needlessly expensive process, altogether unscientific, and unsuitable to the present advanced state of agriculture.

INO'RDINATE PROPORTION, in Geometry, is a proportion in which the terms are placed out of the regular order.

INOSCULA'TION. (Lat. inosculatio.) The union of vessels by conjunction of their extremities. This term is sometimes limited to the communication of trunks or large vessels with each other; and where the ramifications which unite are small or capillary, the vessels are said to *anastomose*.

I'NQUEST. In Law, an inquisition of jurors in causes, civil or criminal, when the facts are referred to their trial, being impanelled by the sheriff for that purpose. Also the persons to whom the trial of fact in any question, civil or criminal, is committed. An inquest of office, or inquisition, is an inquiry made by the king's officer, sheriff, coroner, &c., by virtue of their office, or by writ sent them for that purpose, or by persons acting under a special commission, to inquire concerning any matter which entitles the king to the possession of lands and tenements, or goods and chattels; as forfeiture for offences, wreck, treasure-trove, &c. The king's title in general commences on office found.

INQUISI'TION. The title given to a court armed with extensive criminal authority in various European countries; especially instituted to inquire into offences against the established religion. The first of these tribunals of faith was that established in the south of France after the conquest of the Albigeois in the 13th century. They were established in Spain in the middle of the same century, not without much opposition on the part of the bishops and secular clergy, who, in Castile, long maintained their exclusive spiritual jurisdiction. In 1840, the supreme general inquisition was founded at Seville by Queen Isabella, with the aid of the Cardinal Pedro Gonzalez de Mendoza. This great court, commonly known by the name of the Holy Office, had far more extensive authority than those local tribunals of the same name which had previously been established. Thomas de Torquemada, prior of a Dominican convent, was its first president, with the title of inquisitor-general. The process of the inquisition was widely different from that of all other courts of justice. The kings named the grand inquisitor, who appointed his assessors, some of whom were secular, but the greater part regular ecclesiastics: the counsellors were six or seven in number, of whom one, by the ordinance of Philip III., must be a Dominican. A party who was brought under cognizance of the court by secret accusation was immediately seized by its officers (termed officials or familiars), and his property put under sequestration. If the accused was fortunate enough to absent himself, and did not appear at the third summons, he was excommunicated, and in some cases burnt in effigy. The subsequent process of the court by imprisonment, secret examination, and torture, is well known. Penitent offenders were subjected to imprisonment, scourging, confiscation, and legal infamy. Those convicted, who were sentenced to death, were burnt at the Autos da Fe, which usually take place on some Sunday between Trinity and Advent. During the eighteenth century, the chief officers of the inquisition were for the most part men of intelligence and moderation, and its proceedings chiefly directed against parties guilty of such offences against

decency or religion as would have been punishable in most European countries, although not by an equally arbitrary process. But there were exceptions to this general character; and by the provincial courts of inquisition, of which Spain contained sixteen, some acts of barbarous injustice were committed. According to a common calculation, 340,000 persons had been punished by the inquisition from 1481 to 1808, of whom nearly 32,000 were burnt. In that year it was abolished by Napoleon. It was afterwards re-established by Ferdinand III. in 1814; but having been again abrogated by the Cortes in 1820, it has not been since reconstituted. In Portugal, the supreme court of inquisition was established in 1557. Its history in many respects resembles that of the Spanish court; but in the eighteenth century its power was greatly curtailed by ordinances which required a certain degree of publicity in its procedure. It was abolished by the Cortes of 1821. There were courts of inquisition in various southern provinces of France, the principal that of Languedoc, established at Toulouse, which was first founded after the war against the Albigeois; but their power was limited not long after their creation, and fell into desuetude long before their final abolition. In several Italian states courts of inquisition have been established; but the institution has never taken much hold on the sentiments or habits of the people of that country. It was restored at Rome by Pius VII. after the expulsion of the French, but had jurisdiction only over the faith and conduct of the clergy. Several well-known histories of the inquisition have been published, particularly that of Limbosch. The reader may also consult *Mosheim*, vol. iii.; *Prescott's Ferdinand and Isabella*; *Quart. Rev.* vol. lv.; *Llorente's Hist. of the Inquisition.*

INSANITY. *See* LUNACY, MADNESS.

INSCRI'BED FI'GURE. In Geometry, a circle is said to be inscribed in a triangle when it touches each of the three sides of the triangle. In like manner, it is inscribed in a polygon when it touches all the sides of the polygon. A triangle or polygon is inscribed in a circle when each of the angles of the figure stands on the periphery of the circle. It is a very obvious but remarkable property, that the area of a triangle is equal to the product of the radius of the inscribed circle into half the perimeter of the triangle.

INSCRI'PTION. In Numismatics, words placed in the middle of the reverse side of some coins and medals. *See* NUMISMATICS.

INSECTA. *See* ENTOMOLOGY.

INSECTI'VORA. (Lat. insecta, *insects*, and voro, *I devour.*) The name of a tribe of Zoophagous Mammals, comprehending those which live wholly or chiefly on insects; also of an order of birds in the ornithological system of Temminck.

INSE'RTED COLUMN. In Architecture, one standing, or appearing to stand, partly in a wall.

INSE'RTION, is a term employed in Botany to denote the manner in which one part grows out of another. It was invented at a time when the laws of vegetable structure were unknown, and it was supposed that bodies that really grow from each other were inserted into each other. Thus stamens said to be inserted into a calyx are in reality stamens that adhere to the sides of a calyx.

INSESSO'RES. (Lat. insideo, *I sit.*) A name by which Mr. Vigors has designated his second order of birds, including the *Passeres* and *Scansores* of Cuvier; and which C. Bonaparte applies to a primary division of birds in his *Systema Vertebratorum*, including the *Passeres*, *Scansores*, and *Accipitres* of Cuvier. As the term signifies those birds which perch, it is applicable to numerous species belonging to Linnæan and Cuvierian orders not yet included by later innovations under the term of Perchers or *Insessores.*

INSOLA'TION, or SCORCHING. A local disease of plants, attributable to exposure to too bright a light, which causes an excessively rapid evaporation, the effect of which is to kill the part in which the evaporation takes place.

INSO'LVENCY. In Law, the inability of an individual not engaged in trade to pay his debts. The insolvency of a trader is called Bankruptcy, which see. Several statutes have been enacted successively for the relief of insolvent debtors, by releasing them from imprisonment on surrender of the whole of their effects to their creditors. Their provisions were consolidated in the last general insolvent act (7 G. 4. c. 57.), and are now materially modified by the Act for abolishing Arrest on Mesne Process (1 & 2 Vict. c. 110.). The Insolvent Court consists of four commissioners and other officers; and is a court of record, with power to examine witnesses, compel attendance, &c. The courthouse is in London (Portugal-street); but single commissioners make circuits three times a year through England and Wales. The court proceeds upon petition from prisoners in actual custody; or, if the prisoner do not pray, on petition from a creditor. An order is then made vesting the prisoner's estate and effects in the provisional assignee of the court; which, however, is void if the petition be dismissed. The duty of the provisional assignee is to receive and dispose of the property, and account for the produce to the court. Other assignees are afterwards appointed by the court, in whom the property vests, who must formerly have been creditors; but this appears to be no longer necessary. The insolvent delivers into court a schedule, which must contain a full account of his property. The petition is then heard; and at the hearing creditors may oppose the discharge, and compel a full investigation of the prisoner's accounts. The court may order the discharge either forthwith, or may remand him for a discretionary period, but not exceeding three years, if any frauds or malpractices on his part with reference to the state of his affairs should be detected. The insolvent then executes a warrant of attorney for the amount of his debts which the distribution of his property is inadequate to cover, and other modes are provided by which his future property may be made available for his creditors. It has long been proposed, and is now under contemplation (1840), to unite the bankrupt and insolvent courts.

INSPIRA'TION. (Lat. in, and spiro, *I breathe.*) The act of drawing air into the lungs. *See* RESPIRATION.

INSPIRA'TION. *See* REVELATION.

INSTALLA'TION. (Modern Lat. in, and stallum, *a seat.*) A name applied to the ceremony of instating persons in honours or dignities; as a knight of the Garter in the chapel of St. George at Windsor; a chancellor in a university; or a dean, prebendary, or other ecclesiastical dignitary, in the stall of the cathedral to which he belongs.

I'NSTANT. (Lat.) A part of time or duration in which no succession is perceived. There are three kinds of instants distinguished by the schoolmen; a *temporary*, a *natural*, and a *rational* instant. The first is a part of time immediately preceding another; the second is what is otherwise termed a *priority of nature*, which obtains in things subordinated in acting, as first and second causes, or causes and their effects; and the third is not any real instant, but a point which the understanding conceives to have existed before some other instant, founded on the nature of the things which cause it to be conceived.

INSTA'NTIÆ CRUCIS. In Philosophy, *crucial* instances or examples; a phrase invented by the fancy of Bacon. The use of crucial examples or experiments is to facilitate the process of induction. For example, A and B, two different causes, may produce a certain number of similar effects; find some effect which the one produces and the other does not, and this will point out, as the direction-post at a point where two highways meet (crux), which of these causes may have been in operation in any particular instance. Thus, for example, many of the symptoms of the oriental plague are common to other diseases; but when the observer discovers the peculiar *bubo* or boil of the complaint, he has an *instantia crucis*, which directs him immediately to its discovery. (See, amongst other commentaries on Bacon, *Playfair's Introduction*, and *Ed. Rev.* vol. xxxvi.)

INSTINCT. *See* REASON.

I'NSTITUTE. The principal philosophical and literary society of France, formed in 1795 by the union of four academies. (*See* ACADEMY.) *Institute* is applied also to several works embodying the principles of Roman law; of these the chief are those of Justinian and Gaius.

INSTITU'TIONS. (Lat. instituo, *I instruct.*) In Literature, a term denoting originally a system of the elements or rules of any art or science, but signifying in a more comprehensive sense all associations formed for the improvement of society at large, or the parties immediately concerned, by whatever name they are designated, or to whatever object the labours of the members are directed. Institutions formed for the promotion of learning or science have been distinguished by the name of academies or societies, and associations constituted for commercial purposes are usually styled companies; while those formed for other purposes have various designations, or have some epithet prefixed descriptive of their character.

I'NSTRUMENT, MUSICAL. A musical instrument is one for the production of musical sounds, either by percussion, wind, the drawing a bow across strings, or the production of sound from the vibration of the strings by pulling or pinching them transversely, as in the harp or guitar.

I'NSULATED. (Lat. insula, *an island.*) In Architecture, a term implying that the building to which it is applied is detached from any other. Thus a church is said to be insulated when it adjoins no other building; so also a column is said to be insulated when standing out free from a wall; hence the columns of peripteral temples are insulated.

INSULA'TION. A body is said to be insulated which, containing a quantity of free caloric, or the electric fluid, is surrounded by non-conductors, and the communication with other bodies thereby cut off. *See* ELECTRICITY.

INSU'RANCE. A contract of indemnity, whereby the insurer, in consideration of a certain premium, undertakes

to indemnify the insured against loss arising by the occurring of a contingent event; such as the destruction of houses by fire, the loss of ships at sea, the failure of crops through the inclemency of the seasons.

Insurance is sometimes synonymously used with *assurance;* but the latter term is now more frequently applied to one particular class of contracts, namely, those which depend on the continuance or failure of human life, while *insurance* is applied to risks of all other kinds. For the explanation of the principles on which life assurances are calculated, see ASSURANCE.

In all cases of insurance, the first thing to be determined is the degree of probability that the event under consideration will take place; but it seldom if ever happens that this is known with any moderate degree of precision. Even in the commonest cases, it is perhaps altogether impossible to procure the data necessary for the accurate determination of this element. Suppose, for example, an insurance is to be effected on a ship bound on a voyage to China: in what manner is the probability of its reaching its destination in safety to be determined? Even if an accurate account had been kept of all the voyages made during a century, and the number of successful as well as the number of unsuccessful ones were precisely known, the data would still be very insufficient for determining the risk of the loss of any individual vessel. The loss of a ship is not a simple event like the turning up of a number on the face of a die. The greater or less prevalence of hurricanes at the season of the year when the voyage is to be made; the strength of the ship and sufficiency of its equipment; the skill of the commander, and the character and discipline of the crew,—are all elements materially affecting the risk, but which it is impossible to reduce to numerical values and precise calculation. All, therefore, that can be done is to adopt certain mean or average values, deduced from observations of the fate of vessels in circumstances not indeed precisely the same, but having some degree of similarity. To the insurer, if he sufficiently multiplies his adventures, the result will be the same in the long run as if he had a more accurate appreciation of the separate influences of which the probability of the safe arrival of a vessel at a given port is composed; but the evil which results from this deficient knowledge of facts is, that the owner of a good ship, by paying the same premium for insurance as the owner of a bad one, is charged for indemnification against a risk which he really does not run; and hence the motives for improving the construction of vessels are not only destroyed, but it even becomes an object of pecuniary interest to expend in their equipment nothing beyond what is necessary to give them that moderate degree of goodness or sea-worthiness which suffices to render them insurable on the ordinary terms. This system, however much it is to be deprecated, is rather advantageous than otherwise to the underwriters or insurers; because their premiums are charged in proportion, and it renders insurance more necessary: the pecuniary loss falls ultimately on the million who consume the merchandise; and as to the loss of human life, *that* consideration will probably operate as a check to cupidity only in so far as it may tend to raise the wages of seamen.

With respect to insurances against fire, the exact appreciation of the risk is not less difficult than in the case of marine insurances; but mathematical nicety on this subject is of little importance, for the amount of experience afforded by the general prevalence of the practice, and the competition which exists among the numerous rival companies, have probably had the effect of adjusting the premium to the average risk with all the accuracy which is practically attainable. The premium charged by the London offices for insuring property of the value of 100*l.* for a year is one shilling and sixpence, which corresponds to an average annual loss of nearly one in 1300; but it is to be observed that the sum which is charged as premium is presumed to be sufficient not only to cover the losses, but also to defray the expenses of the establishment, and to afford an adequate interest on the amount of the capital laid out or risked by the insurance company. Notwithstanding the extent to which the practice of insuring is now carried, it is probable that it would be still more general were it not for the circumstance that the government imposes a tax on the transaction of three shillings per annum for each 100*l.* insured, which is double the amount of the premium charged by the insurer. In 1837, the government duty on insurances amounted to 863,196*l.* 12*s.* 3*d.*, which supposes the value of the property insured in that year to have been upwards of 575 millions.

The characteristic property of insurances, of whatever nature, is their tendency to reduce to a certain average value the profits or advantages arising from all speculations of the same kind, however great the number may be. The gain which the insurer makes on his successful speculations indemnifies him for the loss he sustains by those which are unsuccessful; and to the insured the result is the same as if they had paid their premiums into a common fund, and agreed to make good to each other their individual losses. The insurers are only the intermediate agents of this supposed association, and their profits may be regarded simply as the salary of their functions. If other means exist of dividing the risks, insurance becomes unnecessary. A mercantile company employing a very great number of ships, or taking part in a very great number of enterprises, would derive no benefit from insurance. The loss on those which are unsuccessful is compensated by the premiums saved on the whole; in fact the company acts as insurer to itself. On this principle the government neither insures vessels belonging to the royal navy nor public buildings.

INTA'GLIO. (It. intagliare, *to cut in.*) In Sculpture and Gem Sculpture, a stone or gem in which the subject is hollowed out so that an impression from it would present the appearance of a bas relief.

I'NTEGER. (Lat. *entire.*) In Arithmetic, a whole number; as opposed to a fractional number, or a mixed number.

I'NTEGRAL CALCULUS. The branch of mathematical analysis which treats of the processes by which a function may be found such that its differential shall be a given quantity. By English writers this function used to be denominated the *fluent*, or *flowing quantity;* and the method of finding it was called the *inverse method of fluxions.* Foreign mathematicians, who adopted the views and notation of Leibnitz, have called it the *integral* or *sum* of the proposed differential; and this phraseology is now universally adopted by the mathematicians of our own country.

The method by which the integral of a proposed differential quantity is to be found is, generally speaking, neither obvious nor capable of being reduced to fixed and general rules. When an integral is proposed, its differential may always be found by general rules; but there is no direct method of returning from the differential to the integral: the analyst can only compare the differential expression which is to be integrated with the differentials of known quantities, and from such comparison infer the form of the corresponding integral. The principal art employed in the integral calculus consists in transforming the proposed functions into expressions which are known to be the differentials of given quantities.

In order to denote the integral of a quantity, the symbol $\int$ (originally S, the initial letter of the word *sum*) is employed. Thus $\int X\,dx$ denotes the integral of the differential $X\,dx$.

1. To begin with the simplest cases,—Let it be proposed to integrate the expression $x^m\,dx$, or to find the function denoted by $\int x^m\,dx$. It has been shown, under the term DIFFERENTIAL CALCULUS, that the differential of a quantity x^n is $n\,x^{n-1}dx$; that is to say, $d\,x^n = n\,x^{n-1}d\,x$. Let $n = m+1$, and this becomes $d\cdot x^{m+1} = (m+1)\,x^m\,dx$; whence we have $x^m\,dx = \frac{d\cdot x^{m+1}}{m+1}$; or, as the constant quantity $(m+1)$ does not affect the differentiation, $x^m\,dx = d\cdot\frac{x^{m+1}}{m+1}$. But as the integral of an expression $d\cdot P$ is evidently P, the equation gives, on integrating both members, $\int x^m\,dx = \frac{x^{m+1}}{m+1}$. From this we derive the following general rule for integrating a differential of one term: — Increase the exponent of the variable quantity by unity, and then divide by the new exponent and by dx.

It is necessary, however, to remark, that the integral thus formed may either be the expression from which the differential $x^m\,dx$ was derived, or it may be that expression increased or diminished by any constant quantity. For the differential of $a\,x^5$ being $5\,a\,x^4\,dx$, and of $a\,x^5+b$ being also $5\,a\,x^4\,dx$ (b being any constant quantity whatever); it follows that if we have to integrate the expression $5\,a\,x^4\,dx$, the integral will be incomplete, unless we add to it a quantity which though indeterminate does not change its value with the variation of x. We have, therefore, in general, $\int x^m\,dx = \frac{x^{m+1}}{m+1} + C$, where C is a quantity, positive or negative, the particular value of which remains to be determined by the nature of the problem under consideration. This quantity, C, which is necessary in order to complete the integral, was denominated by the older English writers *the correction of the fluent;* in the language of modern analysts, it is *the arbitrary constant.*

2. The differential of a polynomial being composed of the sum of the differentials of its terms taken separately, the integral of a polynomial is in like manner formed by adding into one sum the integrals of its component terms.

Thus,

$$\int (a\,dx + b\,x\,dx - c\,x^n\,dx) = a\,x + \tfrac{1}{2}\,b\,x^2 - \frac{c\,x^{n-1}}{n-1} + C;$$

and one constant is only necessary, for the sum of the constants which arise from the integration of the separate terms may evidently be represented by a single letter. In the same manner, the integral of a function having the form $(a + b\,x + c\,x^2)^n$ may be found when n is a whole positive number, it being only necessary to raise the root to the power denoted by n.

3. By the differential calculus, $d \cdot \log. x = \frac{d\,x}{x}$. When any differential expression, therefore, can be reduced to this form, its integral will be found by means of a logarithm. Thus, supposing it were required to find the integral of $\frac{a\,d\,x}{a + b\,x}$. Suppose $a + b\,x = z$, and we have $d\,x = \frac{d\,z}{b}$. Substitute this in the given expression, and we have $\frac{a\,d\,x}{a + b\,x} = \frac{a\,d\,z}{b\,z}$. But $\int \frac{a\,d\,z}{b\,z} = \frac{a}{b} \int \frac{d\,z}{z} = \frac{a}{b} \log. z + C$; which, on writing for z its value, becomes $\frac{a}{b} \log. (a + b\,x) + C$.

4. An extensive class of differential expressions, of very frequent occurrence in the solution of problems, is integrated by means of circular arcs. Let x be the sine of an arc z, we have then $x = \sin. z$; and by the differential calculus $d\,x = \cos. z\,d\,z$, whence $d\,z = \frac{d\,x}{\cos. z}$. But, by the properties of the trigonometrical lines, $\cos.^2 z + \sin.^2 z = 1$; whence $\cos. z = \sqrt{1 - \sin.^2 z}$, or $\cos. z = \sqrt{1 - x^2}$; consequently $d\,z = \frac{d\,x}{\sqrt{1 - x^2}}$. Transposing the terms of this equation and integrating, we find $\int \frac{d\,x}{\sqrt{1 - x^2}} = z + C$, z being an arc of which the sine is x. Whenever, therefore, an expression occurs of the form $\frac{d\,x}{\sqrt{1 - x^2}}$, we know that its integral, though it cannot be expressed generally in numbers when a numerical value is given to x, is represented by means of an arc of a circle. The expression $\frac{d\,x}{\sqrt{a^2 - x^2}}$ is reducible to the same form; for, on dividing the numerator and denominator by a, or $\sqrt{a^2}$, and making $\frac{x}{a} = u$, we get $\frac{d\,x}{\sqrt{a^2 - x^2}} = \frac{d\,u}{\sqrt{1 - u^2}}$; and $\int \frac{d\,u}{\sqrt{1 - u^2}}$ = arc of which the sine is u, or $\frac{x}{a}$. The constant C in the present case is zero, for the arc and its sine both vanish together.

Let us suppose, in the second place, $x = \cos. z$. By differentiating we find $d\,x = -\sin. z\,d\,z$; whence $d\,z = -\frac{d\,x}{\sin. z} = -\frac{d\,x}{\sqrt{1 - \cos.^2 z}} = -\frac{d\,x}{\sqrt{1 - x^2}}$. Transposing and integrating as before, $\int -\frac{d\,x}{\sqrt{1 - x^2}} = z + C$, z being the arc whose cosine is x. In this case, the constant C must be determined from this consideration that when the cosine of an arc is 0 the arc itself is equal to a quadrant. Supposing, then, $x = 0$, and consequently $\frac{d\,x}{\sqrt{1 - x^2}} = 0$, and denoting the semicircumference as usual by π, the integral becomes $0 = \frac{1}{2}\pi + C$; whence $C = -\frac{1}{2}\pi$. Substituting this value of π, we get $\int -\frac{d\,x}{\sqrt{1 - x^2}} = z - \frac{1}{2}\pi = -(\frac{1}{2}\pi - z)$.

Lastly, let us suppose $x = \text{tang.}\,z$. The differential of the tangent of an arc is equal to the differential of the arc divided by the square of the cosine. Hence $d\,x = \frac{d\,z}{\cos.^2 z}$; and therefore $d\,z = d\,x \cos.^2 z$. But $\cos. z = \frac{1}{\sec. z}$; whence $d\,z = \frac{d\,x}{\sec.^2 z} = \frac{d\,x}{1 + \tan.^2 z} = \frac{d\,x}{1 + x^2}$. Transposing and passing to the integral, we have $\int \frac{d\,x}{1 + x^2} = z + C$. In this case, as the arc and its tangent vanish together, $C = 0$; therefore $\int \frac{d\,x}{1 + x^2}$ = arc whose tangent is x.

To this form we may reduce the expression $\int \frac{d\,x}{a^2 + x^2}$. Divide the terms by a^2, and make $\frac{x}{a} = u$; it then becomes $\int \frac{1}{a} \cdot \frac{d\,u}{1 + u^2}$, or $\frac{1}{a} \int \frac{d\,u}{1 + u^2}$; whence $\int \frac{d\,x}{a^2 + x^2} = \frac{1}{a} \times$ arc whose tangent is $\frac{x}{a}$.

5. In transforming differential expressions into others of which the integrals are known, it is frequently very convenient to employ an artifice which is usually termed *integration by parts*. This consists in making an integral of the form $\int v\,d\,u$ depend on another of the form $\int u\,d\,v$. Thus, by the differential calculus, $d\,(u\,v) = u\,d\,v + v\,d\,u$; transposing and integrating, we get $\int u\,d\,v = u\,v - \int v\,d\,u$, which is the formula by which the artifice in question is accomplished. As an example, let it be proposed to find in this manner the integral $\int x^m\,d\,x$. Make $x^m = u$, and $d\,x = d\,v$; we have then $v = x$, $u\,v = x^m\,x = x^{m+1}$, $d\,u = m\,x^{m-1}\,d\,x$, and $v\,d\,u = m\,x^m\,d\,x$. Substituting these expressions in the formula $\int u\,d\,v = u\,v - \int v\,d\,u$, it becomes $\int x^m\,d\,x = x^{m+1} - \int m\,x^m\,d\,x$; whence (since $\int m\,x^m\,d\,x = m \int x^m\,d\,x$) we have by transposing $(1 + m) \int x^m\,d\,x = x^{m+1}$, and therefore $\int x^m\,d\,x = \frac{x^{m+1}}{1 + m}$, which is the same expression as was given above. It may be remarked, that by the use of this artifice the integral of the expression $x^m\,d\,x$ has been found by differentiating x^m, and making the substitutions ordinarily employed in common algebra.

Another method of integration consists in transforming the given expression into a series, and taking the integrals of the several terms separately. Let it be proposed, for example, to integrate by the method of series the expression $\frac{d\,x}{a + x}$, which is the differential of the logarithm of $(a + x)$. In the first place, $\frac{d\,x}{a + x} = \frac{1}{a + x} \times d\,x$; but on expanding $\frac{1}{a + x}$ into a series by division, we have

$$\frac{1}{a + x} = \frac{1}{a} - \frac{x}{a^2} + \frac{x^2}{a^3} - \frac{x^3}{a^4} + \&c.;$$

and multiplying both sides by $d\,x$, and integrating by the the rules already explained, we find

$$\int \frac{d\,x}{a + x} = \frac{x}{a} - \frac{x^2}{2\,a^2} + \frac{x^3}{3\,a^3} - \&c. + C:$$

that is to say,

$$\log. (a + x) = \frac{x}{a} - \frac{x^2}{2\,a^2} + \frac{x^3}{3\,a^3} - \&c. + C.$$

In order to determine the constant, suppose $x = 0$, and the expression becomes $\log. a = C$; whence, substituting this value of C,

$$\log. (a + x) = \log. a + \frac{x}{a} - \frac{x^2}{2\,a^2} + \frac{x^3}{3\,a^3} - \&c.;$$

a series by which the logarithm of one number may be found from another, when the difference between them is small in comparison of the latter number; or, which is the same thing, when the series converges with sufficient rapidity.

As a second example of this method, let the proposed differential be $\frac{d\,x}{1 + x^2}$, or $\frac{1}{1 + x^2} \times d\,x$. In this case we have

$$\frac{1}{1 + x^2} = 1 - x^2 + x^4 - x^6 + \&c.;$$

whence, multiplying by $d\,x$ and integrating the terms,

$$\int \frac{d\,x}{1 + x^2} = x - \frac{x^3}{3} + \frac{x^5}{5} - \frac{x^7}{7} + \&c. + C.$$

But $\frac{d\,x}{1 + x^2}$ is the differential of the arc whose tangent is x; therefore,

$$\text{arc (tan.} = x) = x - \frac{x^3}{3} + \frac{x^5}{5} - \frac{x^7}{7} + \&c. + C:$$

and as the arc and its tangent both vanish together, the constant C is in this case = 0.

The series which has now been found for the arc in terms of the tangent converges only when the tangent is less than radius, or when x is less than unit; but it may be put under a form which will be convergent when x is greater than unit, or the arc greater than 45°. Thus, the series

$$1 - x^2 + x^4 - x^6 + \&c.$$

was obtained by dividing 1 by $1 + x^2$; but if instead of dividing by $1 + x^2$, we divide by its equal $x^2 + 1$, we shall find

$$\frac{1}{x^2+1}=\frac{1}{x^2}-\frac{1}{x^4}+\frac{1}{x^6}-\frac{1}{x^8}+\&c.;$$

whence

$$\int\frac{dx}{x^2+1}=\int\left(\frac{1}{x^2}-\frac{1}{x^4}+\frac{1}{x^6}-\frac{1}{x^8}+\&c.\right)dx+C;$$

and on multiplying each term of the second member by dx and integrating,

$$\text{arc}\ (\tan.=x)=-\frac{1}{x}+\frac{1}{3x^3}-\frac{1}{5x^5}+\&c.+C.$$

In order to find the constant, we cannot in this case suppose $x=0$, for on this supposition the second member of the equation is infinite; but if we suppose $x=$ *infinity*, the arc becomes a quadrant, or $\frac{1}{2}\pi$, and the equation becomes

$$\tfrac{1}{2}\pi=0+C', \text{ or } 0=-\tfrac{1}{2}\pi+C;$$

and subtracting this equation from the former,

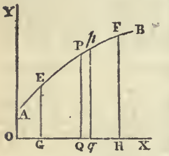
$$\text{arc}\ (\tan.=x)=\tfrac{1}{2}\pi-\frac{1}{x}+\frac{1}{3x^3}-\frac{1}{5x^5}+\&c.$$

which converges the more rapidly the greater we assume the value of x.

The preceding examples will give an idea of the method by which the primitive function is obtained from its differential; but the subject is of by far too extensive and abstruse a nature to be entered into at any length in this place. We shall therefore content ourselves with indicating some of the applications of the integral calculus to geometry.

One of the first objects to which the new calculus was applied by its inventors was the finding of the quadratures, or areas, of curve lines, and their rectification, or the determination of the lengths of their arcs.

Let A B be a curve referred to two rectangular co-ordinates O X and O Y; let E and F be given points in it; and let it be required to find the quadrature of the curvilinear space between E G and F H, the ordinates passing through E and F. Through P any point of the arc E F draw the ordinate P Q, and also $p\,q$ indefinitely near to P Q; then the space P Q $q\,p$ is the differential element of the area G E P Q, and the area itself is equal to the sum of all the differential elements taken between E G and F H. But by the principles of the differential calculus the space P Q $q\,p$ is ultimately (that is, when Q q is less than any assignable quantity) equal to the rectangle under P Q and Q q; therefore, making as usual O Q $=x$, P Q $=y$, and $s=$ the area, we have $ds=y\,dx$, and consequently the area $=s=\int y\,dx$. In order to apply this formula it is necessary, in the first place, to determine y in terms of x by means of the equation of the given curve.



Suppose the given curve to be the common Apollonian parabola, the equation of which is $y^2=a\,x$, a being a constant. From this equation $y=a^{\frac{1}{2}}x^{\frac{1}{2}}$, and consequently $y\,dx=a^{\frac{1}{2}}x^{\frac{1}{2}}dx$; whence, passing to the integral by means of the formula $\int x^m\,dx=\frac{x^{m+1}}{m+1}+C$, we obtain $\int a^{\frac{1}{2}}x^{\frac{1}{2}}dx=\frac{2}{3}a^{\frac{1}{2}}x^{\frac{3}{2}}+C$, which, on substituting for $a^{\frac{1}{2}}$ its value in terms of y, becomes $\frac{2}{3}y\,x+C$. This is the general expression for the area of the parabola; to determine it between the proposed limits we have only to substitute in it the values of x and y at those limits. At the point E it becomes $\frac{2}{3}$ O G · GE + C; and at the point F it becomes $\frac{2}{3}$ O H · H F + C. Subtracting, therefore, the first of these from the second we have the space G E F H $=\frac{2}{3}$ (O H · H F − O G · GE), the indeterminate C being eliminated by the subtraction.

From this example it is easy to see that the space represented by the integral $\int y\,dx$ is the increment which a certain area receives while the independent variable x passes from one state of magnitude to another; and that the absolute magnitude which represents the integral cannot be known before C is determined or eliminated as above. For the purpose of expressing the limits within which the integral is to be taken a particular notation is employed. Let O G $=k$, and O H $=l$; then it is usual to write

$$\text{area G E F H}=\int_l^k y\,dx,$$

to express that the integral includes all values of x, from $x=k$ to $x=l$. The one of these is the value of x at its commencement, the other at its completion; and the integral itself is an indeterminate quantity till the initial and final values of x are assigned.

The rectification of curve lines is another of the earliest applications of the integral calculus. To rectify a curve, signifies to find a straight line equal to its arc. According to the principles of the differential calculus, if z denote the arc of a curve, then $dz=\sqrt{d\,x^2+d\,y^2}$; consequently, if the value of $d\,y^2$ be found by means of the equation of any curve in terms of x (or that of $d\,x^2$ in terms of y) and substituted in this equation, the radical will contain only one variable, and when the expression is capable of being integrated the curve is rectifiable. It is, however, only in a comparatively small number of cases that the differential of the arc of a curve can be integrated in finite terms.

As an example, let us take the circle, the equation of which is $x^2+y^2=a^2$, reckoning the co-ordinates from the centre. From this equation $y=\sqrt{a^2-x^2}$, whence $dy=\frac{-x\,dx}{\sqrt{a^2-x^2}}$, $dx^2+dy^2=\frac{a^2\,dx^2}{a^2-x^2}$, and $dz=\frac{a\,dx}{\sqrt{a^2-x^2}}$. This expression cannot be integrated otherwise than by an infinite series. We have already seen that it is reducible to the form $\frac{dx}{\sqrt{1-x^2}}$. But the expression $\frac{1}{\sqrt{1-x^2}}$ expanded by the binomial theorem gives

$$1+\tfrac{1}{2}x^2+\frac{1\cdot3}{2\cdot4}x^4+\frac{1\cdot3\cdot5}{2\cdot4\cdot6}x^6+\&c.;$$

whence, multiplying by dx and integrating the terms separately,

$$\int\frac{dx}{\sqrt{1-x^2}}=x+\frac{x^3}{2\cdot3}+\frac{1\cdot3\,x^5}{2\cdot4\cdot5}+\frac{1\cdot3\cdot5\,x^7}{2\cdot4\cdot6\cdot7}+\&c.$$

Now, if in this series we write $\frac{x}{a}$ for x, and multiply the whole by a, we shall have

$$\int\frac{a\,dx}{\sqrt{a^2-x^2}}=x+\frac{x^3}{2\cdot3\,a^2}+\frac{1\cdot3\,x^5}{2\cdot4\cdot5\,a^4}+\frac{1\cdot3\cdot5\,x^7}{2\cdot4\cdot6\cdot7\,a^6}\&c.$$

for the length of the arc of the circle whose radius is a and absciss x. Suppose $x=a=1$; this series gives for the length of the quadrant

$$1+\frac{1}{2\cdot3}+\frac{1\cdot3}{2\cdot4\cdot5}+\frac{1\cdot3\cdot5}{2\cdot4\cdot6\cdot7}+\&c.$$

The quadrature and rectification of the circle are problems which have exercised the ingenuity of mathematicians ever since the invention of the science; but the solution neither of the one nor the other can be obtained in finite terms.

The application of the integral calculus to the determination of the volumes and surfaces of solids, is perfectly analogous to the determination of the areas and arcs of plane curves. Supposing the solid to be generated by the revolution of a plane curve about its axis, the expression for its volume is $\pi\int y^2\,dx$, where π is the semicircumference of the circle whose radius is unit. The expression for its surface is $2\,\pi\,y\sqrt{d\,x^2+d\,y^2}$. In these expressions the values of y^2, y, and $d\,y^2$ must be found in terms of x from the equation of the curve by the revolution of which the solid is formed; and when the values thus found are substituted, the formulæ will contain no other variable than x.

The integral calculus also affords the readiest, and, in general, the only means of determining the centres of gravity, of oscillation, gyration, &c.; and is, in fact, the instrument by which mathematicians have succeeded in solving the difficult and important questions of dynamics and physical astronomy, and in ascertaining the laws which regulate the motions of the material world.

As the integral calculus, with its various applications, embodies almost the whole of mathematical science, the treatises which have been composed to explain or illustrate its principles are by far too numerous to be mentioned in this place. Almost all the improvements of the calculus were first given in the form of Academical Memoirs. The great repositories in which it is contained are the writings of Newton, Cotes, Demoivre, the Bernoullis, Maclaurin, Simpson, Euler, D'Alembert, Lagrange, Laplace, Legendre, Monge, Poisson, Gauss, Ivory, &c. The best systematic treatises are Euler's *Calculus Integralis*, in 4 vols. 4to., now very scarce; and Lacroix's *Traité du Calcul Différentiél et du Calcul Intégral*, in 3 vols. 4to. Of the minor works we may mention Bossut's *Calcul Différentiél et Intégral;* Boucharlat; Lacroix's smaller treatise, translated by Babbage, Herschel, and Peacock; and the treatises which have recently been published at Cambridge, particularly those of Hymer, Peacock, Myers, Hind, &c.

INTEGRANT PARTS, in the Corpuscular Philosophy, are the small parts of a body, by the aggregation of which it may be conceived to be formed. *Integrant parts* result from the mechanical division of a body; *constituent parts* from its chemical decomposition.

I'NTELLECT. *See* UNDERSTANDING.

INTE'NDANT. (Lat. intendo, *I give my mind to any thing.*) A title in common use among the French,

applied to persons who have the conduct, inspection, and management of any office or function; as intendants of the marine, of the finances, of provinces, buildings, houses, &c., which are all self-explanatory terms.

INTE'NTIONS, FIRST AND SECOND. A distinction drawn by the schoolmen between those acts of thought which relate to an object out of the mind, and those which consist in the mind's reflex action on its own states of consciousness. Thus the generalizations *animal*, *production*, are *first intentions:* such terms as *abstraction*, *inference*, &c., are the expression of *second intentions*. It is to be regretted that this distinction is disused by modern inquirers, or misunderstood by them, as in particular by Whately. Great ambiguity might be avoided in philosophical language were it closely kept in view; as in such terms as *cause* and *effect*, which may either allude to a connection between natural phenomena in themselves, or to our mode of viewing them derived from the essential laws of the understanding. The distinction was first revived in the present century, in a learned and acute review of Whately's Logic contained in the 115th Number of the *Edinburgh Review*.

INTE'RCALARY DAY. (Lat. calo, *I call*. *See* CALENDAR.) In the Calendar, a day inserted out of the usual order to preserve the account of time. Thus every fourth year containing 366 days, while the other years contain only 365, one of the months in that year must have an additional day, which is called the intercalary day. The additional day was given to February, as being the shortest month, and in the ancient Roman calendar was inserted between the 24th and 25th days. In the ecclesiastical calendar it still retains that place; but in the civil calendar it is the 29th. *See* BISSEXTILE.

INTERCE'LLULAR PASSAGES, in Vegetable Anatomy, are the spaces that exist between the cells, tubes, or vessels of which the tissue of a plant consists. As the cells are usually, and the tubes or vessels are always round, it necessarily follows that when pressed together there will be spaces left between their sides.

I'NTERCOLU'MNIATION. (Lat. inter, *between*, and columna, *a column*.) In Architecture, the distance between two columns measured at the lower parts of their shafts. It is one of the most important elements in architecture, and on it depend the effect of the columns themselves, their proportion, and the harmony of an edifice. Intercolumniations are of five species, viz. Picnostylos, Systylos, Diastylos, Aræostylos, and Eustylos; under which several terms in this work they are defined, and to them the reader is referred.

I'NTERCO'STAL. (Lat. inter, and costa, *a rib*.) A term applied to muscles and vessels situated between the ribs.

I'NTERDICT. (Lat.) In Ecclesiastical History, a spiritual weapon by which the Popes used in former times to reduce individuals or whole states to the most abject submission to their power. In the middle ages it was the most terrible blow which could be inflicted on the people or the prince. When an interdict was laid upon a kingdom all spiritual services ceased; the churches were shut up; the sacraments were no longer administered; no corpses were buried with funeral rites; and all the ministry of the church which was then believed to be the only channel of salvation was forbidden to be exercised. The first memorable occasion on which this method of warfare was adopted was the marriage of King Robert of France with Bertha his cousin, when Gregory V. in 998 issued interdicts against the whole country, and compelled the sovereign to dissolve his union. It had, however, been often used before by bishops; an instance is quoted by Moreri as early as A.D. 870. (See *Gieseler's Text Book*, ii. 117., translation.) The ban under which England was laid in the reign of John by Innocent III. is well known in the history of this country. The latest pretensions to the exercise of this power were assumed by Pius VII., when he issued an inefficient decree against Napoleon in 1809.

INTERDICT. The technical term in Roman law for a decree of the prætor concerning the acquisition, retention, or recovery of property. For an elaborate article on this subject see the *Penny Cyclopædia*.

I'NTEREST. The premium or sum of money given for the loan or use of another sum of money, generally estimated at so much *per cent.*, or per 100*l.* The sum lent, and for which the interest is paid, is called the *principal*, and the sum charged as interest is called the *rate*. The rate will evidently be proportional to the time; for whatever interest is paid for the use of 100*l.* for one year, twice that interest will be required for the use of 100*l.* for two years. The principal added to the interest, or the whole sum paid back to the lender, is called the *amount*.

Interest is either *simple* or *compound*. *Simple interest* is that which is reckoned and allowed upon the principal only during the whole time of the loan; *compound interest* is reckoned not only on the principal sum lent, but also on the interest as it becomes due. It is convenient to treat of these separately.

1. *Simple Interest.* — Let us assume
a = the amount,
p = the principal sum lent,
n = the number of years for which it is lent,
r = the rate, or interest of 1*l.* for one year.

Now, the interest of 1*l.* for one year being r, the interest of p pounds for one year is $p\,r$, and for n years $p\,r\,n$. The amount, therefore, of p pounds for n years, at the rate r, is $p + p\,r\,n$; or, $a = p\,(1 + r\,n)$. From this equation we may determine any one of the four quantities in terms of the others. The four equations are as follow: —

$$a = p\,(1 + r\,n) = \text{the amount,}$$
$$p = \frac{a}{1 + r\,n} = \text{the principal,}$$
$$n = \frac{a - p}{p\,r} = \text{the time in years,}$$
$$r = \frac{a - p}{p\,n} = \text{the rate of interest.}$$

These formulæ suffice for the solution of all questions of simple interest. It is only necessary to observe, that when the time is less than a year, n is a fraction: for example, if the time is seven months, $n = \frac{7}{12}$; and if the time is 100 days, then $n = \frac{100}{365}$. If the rate of interest be 4 *per cent. per annum*, then $r = \cdot 04$; if the rate be 5 *per cent. per annum*, $r = \cdot 05$; and so on.

2. *Compound Interest.* — Though the law does not permit money to be lent at compound interest, yet in purchasing annuities, reversions, leases, &c., or effecting assurances on life, it is always allowed; the subject is therefore of considerable importance.

In order to show the manner in which any given sum increases at compound interest, let us suppose 100*l.* to be lent at the rate of 5 per cent. per annum. At the end of the first year this will amount to 105*l.* Now this 105*l.* may be regarded as a new principal lent out the second year at the same rate; its interest will therefore be 5*l.* 5*s.*; and consequently the amount at the end of the second year is 110*l.* 5*s.* This again may be regarded as a new principal; and in the same manner the amount at the end of the third year will be 115*l.* 15*s.* 3*d.*, and so on for any longer period. At simple interest the amount at the end of any given time will be greater, as the number of payments or times the interest is added to the principal is greater.

As before, let
a = the amount,
p = the principal,
n = the number of years,
r = the rate of interest.

Therefore, since 1*l.* amounts to $1 + r$ at the end of the first year, and as every other sum is increased in the same proportion, we have $1 : 1 + r :: 1 + r : (1 + r)^2$ = the amount of 1*l.* at the end of the second year. In like manner, we have $1 : 1 + r :: (1 + r)^2 : (1 + r)^3$ = the amount at the end of the third year, and so on. In general, the amount of 1*l.* at the end

of the 1st year $= 1 + r$
2d $= (1 + r)^2$
3d $= (1 + r)^3$
4th $= (1 + r)^4$
nth $= (1 + r)^n$.

The amount, therefore, of any principal p, at the end of n years, is $p\,(1 + r)^n$; and from this we derive the following formulæ for finding any one of the four quantities when the three others are given: —

$$a = p\,(1 + r)^n = \text{the amount,}$$
$$p = a\,(1 + r)^{-n} = \text{the principal,}$$
$$n = \frac{\log.\,a - \log.\,p}{\log.\,(1 + r)} = \text{the number of years,}$$
$$r = \left(\frac{a}{p}\right)^{\frac{1}{n}} - 1 = \text{the rate of interest.}$$

As an example, suppose it were required to find in how many years a sum of money lent at compound interest, at 5 per cent. per annum, would double itself. Here the quantity to be found is n, and we must apply the third formula. We have in the present case $a = 2\,p$, and $1 + r = 1{\cdot}05$; therefore, $n = \frac{\log.\,2\,p - \log.\,p}{\log.\,1{\cdot}05} = \frac{\log.\,2}{\log.\,1{\cdot}05} = \frac{3010300}{0211893} =$ 14·2067 nearly; therefore, at the rate of 5 per cent. per annum, any sum of money doubles itself in $14\frac{1}{5}$ years.

In the above formulæ the interest is supposed to be payable yearly, and r denotes the simple interest of 1*l.* for one year; but if the payments become due at different intervals from a year, then r will not be the *annual* rate of interest actually yielded by the principal, but the nominal rate which determines the amount of the first payment. For example, suppose the payments due half-yearly, and the nominal interest or simple interest for a year 5 per cent.; 100*l.* principal will produce 2*l.* 10*s.* of interest the first half year. But the interest the second half year being on 102*l.* 10*s.*, will be 2*l.* 11*s.* 3*d.*; so that

while the nominal interest is 5 per cent., the interest actually made in a year on 100*l.* is 5*l.* 1*s.* 3*d.*

The advantages arising from a sum of money put out to compound interest for shorter periods than a year may be determined as follows: — Suppose the payments to be made half-yearly; then each payment being half of the annual simple interest, the amount of 1*l.* at the end of the year will be expressed by $\left(1+\frac{r}{2}\right)^2$, which is equal to $1+r+\frac{r^2}{4}$. But the amount at a yearly payment is $1+r$; the advantage, therefore, of the half-yearly payment is $\frac{1}{4}$th of the square of r. If the payments of interest be supposed to be made quarterly, then the amount of 1*l.* at the end of the year will be expressed by $\left(1+\frac{r}{4}\right)^4=1+r+\frac{3r^2}{8}+\frac{r^3}{16}+\frac{r^4}{256}$, which exceeds the amount, when the payment is yearly, by $\frac{3r^2}{8}+\frac{r^3}{16}+\frac{r^4}{256}$, or by $\frac{3r^2}{8}$ nearly, the remaining terms being very small, and of scarcely any sensible value. Generally, if the interest is payable m times a year (each payment being the mth part of the annual simple interest), the amount of 1*l.* at the end of the year will be expressed by

$$\left(1+\frac{r}{m}\right)^m=1+r+\frac{m-1}{2m}r^2+\frac{(m-1)(m-2)}{2\cdot 3m^2}r^3+\frac{(m-1)(m-2)(m-3)}{2\cdot 3\cdot 4m^3}r^4+\&c.$$

As r is a small number, all the terms of this series multiplied by the cube and higher powers of r may be omitted, and the amount becomes $1+r+\frac{m-1}{2m}r^2$, which exceeds the amount when the payment is yearly by $\frac{m-1}{2m}r^2$. If we suppose m to be infinitely great, or the interest to become due and to be added to the principal *momently*, the series becomes

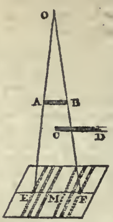
$$1+r+\frac{r^2}{1\cdot 2}+\frac{r^3}{1\cdot 2\cdot 3}+\frac{r^4}{1\cdot 2\cdot 3\cdot 4}+\&c.;$$

which is equal to the number whose Napierean logarithm is r, or the number whose logarithm is $r \times \cdot 4342945$ in the common tables. Suppose the rate to be 5 per cent., we have $\cdot 05 \times \cdot 4342945 = \cdot 0217147$, the natural number corresponding to which is 1·05127; consequently the amount of 100*l.* at 5 per cent., on the hypothesis of *momently* payments for a year, is 105·127*l.* = 105*l.* 2*s.* 6½*d.* nearly, exceeding the amount at simple interest only by 2*s.* 6½*d.*, which differs very little from $\frac{1}{2}r^2$.

INTERFE'RENCE. In Optics, a term first employed by Dr. Young to express certain phenomena which result from the mutual action of the rays of light on each other. The phenomena in question are considered of very great importance, and have accordingly been examined with great care, on account of the proof which they are supposed to give of the truth of the undulatory theory of light.

The phenomena may be thus explained: — Suppose two minute pencils of light, radiating from two different luminous points, to fall on the same spot of a screen or piece of paper, and making a small angle with each other. If the spot on which both pencils fall is at the same distance from both foci or luminous points, the intensity of the illumination is greater than would have been produced by either pencil alone. Now it has been found that there is a certain difference between the lengths of the paths at which the intensity of illumination produced by their concourse is the same as when the paths are equal. Call this difference d; then it is also found by experience that similar bright bands or fringes are produced when the difference between the lengths of the paths of the two pencils is $2d$, or $3d$, or $4d$, &c. But it is very remarkable that when the difference between the lengths of the two paths is $\frac{1}{2}d, \frac{3}{2}d, \frac{5}{2}d$, &c., the two pencils, instead of adding to each other's intensity, destroy one another, and produce a black spot or fringe. The two pencils thus act on each other, increasing the effect in one case and diminishing it in another; and it is this mutual action which is called *interference*.

In order to study the phenomena in detail, Dr. Young admitted a pencil of homogeneous light into a darkened chamber through a hole made with a fine needle in a sheet of paper, and observed at different distances the shadow of a thread or opake disc (the diameter of which did not exceed 1-30th of an inch) placed a little behind the opening. Having remarked that the shadow received on a screen was divided by parallel bands, of which that in the middle was always white, he proved that the bands were produced by the interference of the rays passing by the two sides of the thread or disc. This was demonstrated by intercepting the light which fell on one of the sides of the disc by means of a screen placed between the disc and shadow, and allowing it to pass freely by the other side, as represented in the annexed figure; in which O is the hole, A B the disc, E F its shadow, and C D the interposed screen, the border of which receives the shadow of the side B of the disc. The instant the screen is brought within the shadow of A B, all the fringes of the shadow immediately disappear, although the light inflected by the side of the disc A continues to follow the same route as before; which necessarily supposes that it receives some modification from the proximity of that which passes by the side B.



The field of inquiry which had thus been opened by the ingenuity of Dr. Young was explored to a much greater extent by Arago and Fresnel. Instead of the screen C D, Arago introduced the edge of a thin plate of glass into the shadow of the disc, and found that the luminous fringes received various modifications, according as the plate of glass was more or less thick. When the plate was of a certain thickness, the central fringe M was brought nearer to F, and the first dark fringe on the same side occupied the place which had before been occupied by the second; the second took the place of the third, and so on. On the other side of M the appearance was the reverse; the third fringe took the place of the second, the second of the first, and the first was brought into the middle of the spectrum at M. On using glass a little thicker, the displacement was doubled; the first fringe fell upon the place of the third, the second on that of the fourth, and so on. This experiment of Arago proves that the mutual action of the rays does not alone depend on a particular modification which the rays receive at the boundaries of a body which they graze in their course, but also on the different media which they traverse from their source to the point where they interfere.

Fresnel adopted a still more ingenious method of performing the experiment. Having placed two plane metallic mirrors in a vertical position, and so as to make a very obtuse angle with each other, he concentrated, by means of a lens of small focal length, a pencil of homogeneous light directed horizontally, at a point so situated before the mirrors that part of the diverging cone fell upon the one mirror and part of it upon the other. The rays of light reflected from the two surfaces being rendered convergent by the position of the mirrors, again met each other at a small angle; and at the point of intersection produced alternations of brilliant and dark fringes. These fringes are parallel to the line of intersection of the two mirrors, and on screening one of the mirrors they immediately disappear.

In the experiment of Dr. Young and Arago it might be supposed that the fringes were produced by some physical action of the interposed body on the light; but in Fresnel's experiment the light is reflected in the usual way, and no question can be raised about the influence of the body by the borders of which it passes. The fact is thus established beyond all doubt, that two rays of light, issuing from a common source, and after pursuing a different path meeting again under a small obliquity, exercise an influence on each other to the extent of doubling the intensity of the light on the one hand, or destroying it altogether on the other. The phenomenon of two rays of light neutralizing each other and producing their mutual extinction, is one of the most remarkable in the whole range of physical science. Though first explained by Dr. Young and established by the Arago and Fresnel, it had formerly been observed and described by Grimaldi.

The fact of the interference of the luminous rays having been established, it was interesting to determine the constant interval d, or difference between the lengths of the paths of the two pencils at which the greatest effect is produced. This interval has been very carefully determined both by Fresnel and by Fraunhofer, and is found to be different for the different colours. The following are values of d found by Fraunhofer for the different colours of the spectrum, expressed in decimals of an English inch: —

Red - - -	d = 0·00002582
Orange yellow - -	= 0·00002319
Green - - -	= 0·00002073
Blue - - -	= 0·00001912
Indigo - - -	= 0·00001692
Violet - - -	= 0·00001572

These values of d, being obtained by direct experiments, are independent of any hypothesis respecting the propagation of light: they are equally real, whether light be supposed to be emitted from a luminous body, or produced by the vibrations of an elastic medium; or rather they are numerical conditions which must be satisfied by any theory of light which may be adopted. But the phenomena of interference are scarcely susceptible of probable explanation by the theory of emission; whereas, if

we adopt the undulatory hypothesis, their explanation is remarkably simple. Indeed, they afford the most decisive reasons yet known for adopting that theory in preference to the other. According to the undulatory system, the phenomena are thus explained: —

If two luminous waves reach an ethereal molecule at the same instant of time, it will receive two simultaneous impulsions, and the resulting motion will be directed in the diagonal of the parallelogram of which the two sides represent the impulsions: consequently, if the component velocities are nearly in the same direction, the resultant will be nearly equal to their sum; and if they are in opposite directions, equal to their difference. Let us now suppose, 1st, that two vibratory movements produced by a series of equal and successive undulations indefinitely repeated in an elastic medium are simultaneously experienced at the same point, situated at any distance from their common centre; 2d, that after having followed different paths, their directions at this point are sensibly confounded; 3d, that in consequence of the unequal lengths of the two paths, or of their unequal velocities, the time which a wave takes to arrive at the point by the first path (A) is shorter than that which it takes to arrive by the second path (B). These suppositions being made, it is evident that an ethereal molecule situated at a point common to the two paths A and B will begin to vibrate in consequence of the undulations propagated along A before the undulation which comes by B reaches it; and when this second undulation does take effect, the motion of the ethereal particle will be increased or diminished according as the new impulse conspires with or opposes the former. Three cases may occur: —

1. The difference of the lengths of the paths, or the difference of velocities, may be such that the wave coming by the path B may reach the molecule at an interval of time after it has been affected by the wave coming by A precisely equal to that of a semi-vibration. In this case, the vibrating molecule having reached its limit of excursion on one side, and about to return to the point of repose, would at that instant receive an impulse constraining it to move in the opposite direction with the same velocity. The coexistence of the two systems of vibrations would therefore destroy the motion, and the molecule would remain at rest. The same thing will take place if the difference of the lengths of the paths or velocities is such that the vibrations propagated along B arrive at the intersection of the paths precisely $\frac{3}{2}$, $\frac{5}{2}$, $\frac{7}{2}$, &c. of a period of undulation after those which come by A.

2. The undulations propagated along B may arrive at the molecule after those coming by A at an interval of time exactly equal to that of a complete vibration, or of several vibrations; in which case the molecules would receive the impulse of two vibrations conspiring together, and consequently the velocity and amplitude of its excursions would be doubled instead of being destroyed.

3. The interval between the two impulses may be neither an odd nor an even multiple of the time of a semi-vibration. In this case, the molecule will vibrate with a velocity less than the double of that which it would have if each impulse took place independently of the other. (*Herschel's Treatise on Light*, in the *Ency. Metropolitana*.)

It is a strong presumption in favour of the undulatory theory of light, that it affords not only a complete and satisfactory explanation of the whole of the phenomena of diffraction, but also the means of submitting them to arithmetical calculation. *See* LIGHT.

I'NTERIM. (Lat. *in the mean time.*) In modern European History, the name given to a decree of the Emperor Charles V. after the overthrow of the Protestant League of Smalcalde, in which he attempted to reduce to harmony the conflicting opinions of the Protestants and Romanists. The use of the cap, however, and the marriage of the clergy, were the only points which he conceded to the Reformers; and it became a question among them, and gave rise to many serious disputes, whether they could conscientiously submit even to a temporary decree of such a nature. The enactments of the *interim* were intended only to remain in force till some definitive settlement could be made; whence it derives the name by which it is generally known. It received the force of law at the Diet of Augsburg, in 1548. Its provisions against the Protestants were, however, in most respects set aside by the treaty of Passau, 1552. (See *Mosheim*, vol. iv.)

INTERJE'CTION. In Grammar, a part of speech expressing simple emotion, without involving any act of conception. *See* GRAMMAR.

INTERLO'CUTOR. (Lat. inter, and loquor, *I speak.*) In Literary phraseology, a person who is introduced as taking part in a dialogue; in Dramatic literature, termed *dramatis persona*: the latter name, however, comprehends such as appear on the stage but take no part in speaking, termed by the Greeks mute personages.

INTERLO'CUTORY JUDGMENTS. In Law, such as are given in the course of a cause upon any proceeding arising out of it, and do not finally determine it: as, the judgment in an action of damages upon which a writ of inquiry issues to assess such damages. So a decree in chancery is either final or interlocutory. — In Scottish law, a judgment of the court of session, or lord in ordinary, which if allowed to become final will be conclusive, is termed interlocutor.

I'NTERLUDE. (Lat. inter, *between*, and ludo, *I play.*) A short dramatic piece, generally accompanied with music: properly, such as is represented or performed between the acts of longer performances.

I'NTERMEDE, or INTERMEZZO. In Dramatic Literature, nearly the same with interlude. A short musical piece, generally of a burlesque character; but many not intended merely for introduction between the acts of a more serious performance, are comprised under these names by the French and Italians.

INTERMI'TTENT. Any disease which ceases for a time and again returns, so that the patient is free from it in the intermediate intervals. *See* AGUE.

INTERMI'TTING SPRINGS, are springs which after having run for a certain time stop altogether, and after a time begin to run again, and then stop; and so on alternately, the flowings and intermissions generally succeeding each other at pretty regular intervals. These phenomena, which often excite wonder in the ignorant, and have sometimes even been ascribed to the influence of witchcraft, are explained on the principle of the siphon. Let A be cavern in a mountain, and *a b c* a channel communicating with A, and terminating in the side of the mountain or adjacent plain; and let us suppose the cavern to be fed by small streamlets of water, of which the united supply is less than can be discharged by the channel *a b c*. Let the cavern be supposed empty.

The water from the rills or fissures by which it is fed will collect at the bottom, and as it rises in the cavern will also rise in the channel *a b* till it reaches the highest level *b*, when it will begin to flow out through *b c*, and by the property of the siphon will continue to flow till the whole cavern is drained to the level of *a*. The cavern then begins to fill anew, and the same series of phenomena is repeated at intervals, of which the length depends on the relative capacity of the cavern and channel, and the abundance of the supply through the fissures. When the supply is constant, the intervals of intermission will be equal. Some springs of this kind do not cease altogether to flow, but only discharge a much smaller quantity for a certain time, and then a greater quantity. In this case they are called variable or reciprocating springs. They may be caused by the circumstance of a smaller fissure connecting the cavern with the lower part of the channel *c*, through which a portion of water continues to flow while the main discharge is stopt; or there may be several siphons all communicating with a common outlet. It is easy to imagine a combination of circumstances by which the discharge of water will be greatly increased by the elastic force of air compressed at the top of the cavern A. This will take place when the fissures which communicate with the external atmosphere are filled with water, and there is in consequence no opening by which the air in the cavern can escape. The water will then be propelled through the channel with considerable force, or even raised in a jet, by the very same principle as in the fountain of Hero. (See *Musschenbrock*, Introd. t. ii. § 2379.; *Desaguliers, Exper. Phil.* vol. ii. p. 173.; *Nicholson's Phil. Journ.* xxxv. p. 178.; *Ferguson's Lectures on Select Subjects*, by Brewster.)

INTERMODI'LLION. (Lat. inter, *between*, and modillion.) In Architecture, the space between two modillions, which is equal throughout the entablature.

I'NTERNODE. (Lat. inter, and nodus, *a knot.*) In Botany, the space that intervenes upon a branch between the leaves.

INTERNU'NTIUS, or INTERNUNCIO. An envoy of the Pope, sent to small states and republics; distinguished from the nuncio, who represents the Pope at the courts of emperors and kings. Also a species of diplomatic officers, who ranked, according to the old practice, between ambassadors and plenipotentiaries. Since the Congress of Vienna, as no mention of internuncios is made in its rules, they are considered on a level with plenipotentiaries. This is (or lately was) the title of the Austrian envoy at Constantinople.

INTERO'SSEOUS MUSCLES. Small muscles between the metacarpal bones of the hand and the metatarsal of the foot: the former are concerned in moving the fingers, and the latter the toes.

INTERPILA'STER. (Lat. inter and pilaster.) In Architecture, the space between two pilasters, which depends entirely on the same rules as intercolumniation, and that more especially if both are employed in the same building.

INTERPLE'ADER. In Law. A bill of interpleader, in equity, is filed by a person who is under an obligation of debt or rent to one of the parties to a suit in equity,

but cannot ascertain, until the determination of the suit, to which of the parties he is indebted; and by this bill he desires to interplead, in order that he may save himself harmless in the event of the success of either party. In the common law courts, by 1 & 2 W. 4. c. 58., relief can be given in some cases against adverse claims made on sheriffs and other officers, and persons having no interest is the subject of such claims, by a judge's order calling on the third party to appear and maintain or relinquish his claim.

INTERPOLATION. In Algebra and Astronomy, is a method employed for filling up the intermediate terms of a series of numbers or observations, by numbers which follow the same law. The general problem to be resolved is this: — Given two series of numbers, the corresponding terms of which have some determinate relation to each other, and of which the first is called the series of roots, and the second the series of functions; to find the function corresponding to any term in the series of roots from the numbers in the series of functions which precede or follow that which is required. Thus, supposing the series of roots to be the natural numbers 101, 102, 104, 105, and the series of functions to be the logarithms of those numbers; then the question may be to find the logarithm of 103 by means of the logarithms of 101, 102, 104, and 105. In the language of algebraists, the problem is to determine the value of Y_{x+n} in a function of the terms which precede or follow Y_x.

In Astronomy and Physics, interpolation signifies the method of finding a mathematical law which will connect together a number of observed facts. Thus, supposing 20 places of a comet have been determined by observation; these places are said to be interpolated when a curve defined by an analytical equation has been found which passes through them all, for by means of this curve the place of the comet at any intermediate time can be found. According to this view of the subject, the problem of interpolation is altogether indeterminate; for an infinity of analytic curves of different forms may be found which will pass through 20 given points: but in general the circumstances of the question impose such restrictions as render it determinate. In the instance now given we know that the curve must be an ellipse; and as an ellipse cannot be made to pass through 20 points taken any how, the question resolves itself into this: — To find the ellipse which will *most nearly* pass through the given points, or represent the given observations. Another question now arises, — what conditions must be fulfilled in order that the observations may be represented *most nearly?* These conditions must be determined from other considerations. Suppose the condition to be that the sum of the squares of the errors of observation (that is, of the differences between the observed places of the comet and the corresponding places in the orbit to be found) shall be a minimum; the problem is now quite determinate, though its solution may be sufficiently difficult and laborious.

The method of interpolation by differences was first employed by Briggs in the calculation of logarithms; but was afterwards treated in a more general way by Wallis, Newton, Cotes, Stirling, and others. In the fifth lemma of the third book of the *Principia*, Newton has given a solution of the problem of determining the curve which passes through the extremities of any number of ordinates. By modern writers the subject is treated as a branch of the calculus of finite differences. It is discussed at length by Laplace in the 2d vol. of the *Mécanique Céleste*, and also in the *Theorie Analytique des Probabilités;* by Lagrange, in the *Journal de l'Ecole Polytechnique*, &c. See also the Treatise on Differences and Series by Sir John Herschel in the Appendix to the English translation of Lacroix's *Differential and Integral Calculus*, or the 3d vol. of Lacroix's large Treatise.

INTERRE'GNUM. (Lat.) The period between the death of one king and the accession of another under the Roman monarchy; or under the republic, the space of time when there were by some accident no curule magistrates who could hold the public assemblies of the people (comitia), during which an interrex was appointed. *See* INTERREX.

I'NTERREX. A person appointed to discharge the royal functions during a vacancy of the throne. The Romans first elected an interrex after the death of Romulus, and the custom was continued while the monarchy lasted. The manner of their election was this, — the senate chose ten individuals out of its body, each of whom discharged the functions of royalty for five days in an order appointed by lot. It has been supposed that these ten senators were not elected, but they were the respective seniors of the ten decuries into which the original body of patricians was divided, and that this office devolved on them by virtue of their rank. An interrex was also appointed sometimes under the republic to preside over elections of magistrates, &c. when the consuls were absent, or their election declared void and no dictator had been created.

INTERSCE'NDENT. (Lat. inter, and scando, *I climb.*) In Algebra, a term applied by Leibnitz to quantities when the exponents of their powers are irrational. Such expressions are called *interscendent*, as holding a mean as it were between algebraic and transcendental quantities.

INTERSE'CTION. (Lat. inter, and seco, *I cut.*) In Geometry, the meeting or concourse of lines or surfaces. The intersection of two lines, or of a line and a surface, is a point; and the intersection of two surfaces is a line.

I'NTERTIE. (Lat. inter, and tie.) In Architecture, an horizontal piece of timber framed between two posts in order to tie them together.

I'NTERVAL. (Lat. intervallum.) In Music, the imaginary distance between two sounds as respects their acuteness and gravity, called by the ancients a *diastem.* Intervals are divided into *simple* and *compound;* the former being without parts or divisions, the latter consisting of several smaller intervals.

INTERVE'NTION. (Lat. inter, and venio, *I come.*) In Politics, the interposition of one state in the domestic affairs of another. The right of armed interveniton is one of the most contested portions of the public law of nations; as, although practised frequently enough by the more powerful with reference to the weak, it had never been regarded otherwise than as a permitted abuse of power until the time of the congresses of Vienna, Laybach, &c., when it was publicly recognized by the leading cabinets of Europe.

INTE'STACY. (Lat. in the sense of *without*, and testor, *I testify.*) In Law, the condition of a party who dies without having made a will. Freehold lands and tenements in which he has an estate of inheritance descend to his heir, subject to such charges as affect real estate; copyhold lands of inheritance to the heir, by the custom of the manor; chattels must be distributed (subject to debts), by the party who takes out letters of administration to the deceased's estate and effects, according to the provisions of the Statute of Distributions.

INTESTINALIA, *Intestinal Worms.* (Lat. intestina, *an intestine.*) The name by which Linnæus and Cuvier have designated the class of animals which infest the interior of other animal bodies, and which indicates their most common locality, viz. the intestinal tube.

The knowledge of the intestinal worms, as a distinct class of invertebrate animals, is of a very late date. In the twelfth edition of the *Systema Naturæ*, 1787-8, only eleven species of true Entozoa are enumerated, and of these only six are placed among the *Intestina* — *Gordius medinensis*, *Ascaris vermicularis*, *Ascaris lumbricoides*, *Fasciola hepatica*, *Fas. intestinalis*, and *Fas. barbata;* the remaining species, viz. *Hydra hydatula*, *Tænia solium*, *Tæn. vulgaris*, *Tæn. lata*, and *Tæn. canina*, are ranged with the Zoophyta. *Bloch's Treatise on the Generation of Intestinal Worms*, and the succeeding work of Goeze, entitled *Versuch einer Naturgeschichte der Eingeweidewürmer Thierischer Körper*, 1782, added largely to the number of the described species, and led to the foundation of some accurately defined groups, and better ideas of classification. Gmelin, availing himself of the labours of these authors, and combining with them the species described by Redi, Pallas, O. F. Müller, and Werner, was enabled to give two hundred and ninety-nine species of *Intestinalia*, in the thirteenth edition of *Linne's Systema Naturæ;* but of this labour it has been justly remarked, "Gmelinus, auctorum plurimorum observationes congessit, sed tam judicio et experientia quam sollertia destitutus, plurima miscuit et implicuit, ut in synonimis ab eodem perperam allegatis, extricandis, C. A. Rudolphi et Zederus multum desudaverint."

The first clear definition of the intestinal worms as a class, and their distribution into a system of orders and genera, are contained in the great work by Rudolphi, entitled *Entozoorum seu Vermium Intestinalium Historia Naturalis*, 8vo. 1808-10. In this work, Rudolphi, after dividing the great class *Vermes*, of Linnæus, into four classes, viz. *Mollusca*, *Gymnodela*, *Entozoa*, and *Phytozoa*, characterizes the third class as follows: — "Entozoa ergo classem, aut si mavis ordinem sistunt peculiarem continentem, *aliis in animalibus obvia, oculis nudis conspicua, nervis carentia, partibus internis dissimilibus instructa.*" Of the class of animals thus characterized, Rudolphi enumerates, in a subsequent work, *Synopsis Entozoorum*, 1819, upwards of eleven hundred species. At the present time, nearly double that number of Entozoa are known.

Rudolphi distributes the intestinal worms into five orders, which are characterized as follows: —

Order I. *Nematoidea* (Round-worms). — Char.: Body elongated, rounded, elastic; an intestinal canal, with a separate mouth and vent; sexes distinct.

Order II. *Acanthocephala* (Hooked-worms). — Char.: Body roundish, utricular, elastic; head with a retractile proboscis, armed with hooks or recurved spines; sexes distinct.

Order III. *Trematoda* (Fluke-worms). — Char.: Body soft, rounded, or flattened; suctorial pores; male and female organs in the same individual.

Order IV. *Cestoidea* (Tape-worms).—Char.: Body elongated, flattened, soft, continuous, or articulated; head either simply labiated, or provided with pits (*bothria*), or suctorious orifices, either two or four in number; male and female organs in the same individual.

Order V. *Cystica* (Hydatids).—Char.: Body flattened or rounded, continued posteriorly into a cyst, which is sometimes common to many individuals; head provided with two or four pits, or with four suckers, and with a circle of hooklets, or with four unarmed or uncinated tentacles; sexual organs hitherto indiscernible.

The Entozoa which are included in the last four orders of Rudolphi have no distinct intestinal canal; and Cuvier considered the presence of this structure in the *Nematoidea* of Rudolphi of sufficient importance to form the character of a primary group, equivalent to all the remaining orders combined; and he observes that the orders thus distinguished might form two classes.

The first order Cuvier terms *Cavitaires;* and he includes in it not only the Nematoid Entozoa, but also the genus *Pentastoma* of Rudolphi, and the Epizoa, or *Vers rigidules*, of Lamarck.

The organization of the *Pentastomata*, which were defined, prior to Rudolphi, by Froelich, under the name of *Linguatula*, unquestionably entitles them to rank with the highest organized Entozoa (see *Zoological Trans.*, vol. i. p.381. pl. 41.); but, with respect to the Epizoa, or the external Lernæan parasites of fishes, although they agree with the *Nematoidea* and all other Entozoa in the absence of distinct respiratory organs, yet the ciliated natatory extremities which they possess in the young state, and the external ovarian appendages of the adult, are characters which raise them above the Entozoa, and indicate their intimate relations with the Siphonostomous Crustaceans.

I have, therefore, combined the *Nematoidea* of Rudolphi with the genera *Linguatula*, *Porocephalus*, and *Syngamus*, &c., which, under the habit of Cestoid or Trematode worms, mask a higher grade of organization, to form a class under the name of *Cœlelmintha*. This class already embraces the types of three different orders, of which one is formed by the *Nematoidea* of Rudolphi; and a second has been established by Diesing, for the *Linguatula*, and other congeneric species, under the name of *Acanthotheca*. The remarkable organization of the genus *Syngamus*, as described by Siebold, clearly indicates the type of a third order of *Cœlelmintha*. (See that word.)

The four orders of intestinal worms which have no distinct intestine, but in which the digestive function is carried on in blind canals, excavated in the parenchymatous substance of the body, Cuvier combines into a group, which he terms *Vers intestinaux parenchymateux*, and for which I have proposed the name of *Sterelmintha*. (See that word.)

This group Cuvier subdivides into three families, or orders; the first corresponding to the *Acanthocephala* of Rudolphi, the second to the *Trematoda*, and the third being equivalent to the *Cestoidea* and *Cystica* combined; with the exception of the genus *Ligula* of Bloch, of which Cuvier makes a fourth order, restricting to it the application of Rudolphi's term *Cestoidea*. To this distinction it must be objected that the passage from the *Tæniæ* to the *Ligulæ* is rendered very gradual by the traces of bothria and of generative organs, which make their appearance in the higher-organized *Ligulæ* which infest the intestines of certain aquatic birds, and respecting which Rudolphi hazards the following ingenious hypothesis; viz., that these species are actually the more simple *Ligulæ* of fishes, developed into a higher grade of organization by virtue of the warmth and abundant nutriment which they enjoy in the intestines of the birds that have swallowed the fishes so infested. To the conjunction of the hydatids with the tapeworms no sound objection can be made: the structure of the *Tetrarhynchi* and *Anthocephali*, on the contrary, shows how unnatural is the separation of the Cestoid from the Cystic Entozoa. The *Cysticercus fasciolaris* may be regarded as the point of transition, or of conjunction, between the two groups. The head in *Cænurus* and *Echinococcus* presents the form and structure of that of *Tænia;* and the head of the *Tetrarhynchus*, the proboscis excepted, precisely resembles that of the *Echinococcus*, although the *Tetrarhynchi* neither inhabit a vesicle, nor terminate in a vesicle. The *Cystica* appear, in fact, to be incomplete *Cestoidea:* both consist at first of a simple cyst, like the *Acephalocyst;* but both proceed to develope therefrom a suctorious and uncinated head, from which the *Cestoidea* proceed to develope not only ova, but generative organs, in successive segments, which in some species, as the *Bothriocephalus punctatus*, seem to be annually shed and reproduced.

Thus, the intestinal worms, as at present known, form two classes, each divisible into three orders.

Class I. Cœlelmintha.

Order 1. *Nematoidea.*—Ex.: *Filaria medinensis*, *Fil. oculi*, *Fil. bronchialis*, *Ascaris lumbricoides*, *Asc. vermicularis*, *Tricocephalus dispar*, *Spiroptera hominis*, *Strongylus gigas*, *Strong. spiniger*, *Trichina spiralis*.

Order 2. *Acanthotheca.*—Ex.: *Linguatula tænioides*.

Order 3. *Syngamoidea.*—Ex.: *Syngamus trachealis*.

Class II. Sterelmintha.

Order 1. *Acanthocephala.*—Ex.: *Echinorhynchus gigas*.

Order 2. *Trematoda.*—Ex.: *Distoma hepaticum*, *Polystoma pinguicola*.

Order 3. *Tænioidea.*—Ex.: *Bothriocephalus latus Tænia solium*, *Cysticercus cellulosæ*, *Echinococcus hominis*.

The examples quoted are species which infest man, with the exception of those belonging to the orders *Acanthotheca*, *Syngamoidea*, and *Acanthocephala*, which have no representatives among the human internal parasites. For the parts of the body which these latter infest, the reader is referred to Entozoa.

INTE'STINE. The convoluted membranous and muscular tube extending from the pylorus to the anus. It is distinguished into small and large intestines: the former including the *duodenum*, the *jejunum*, and the *ileum;* the latter the *cæcum*, *colon*, and *rectum*. The small intestines have internal membranous folds, called *valvulæ conniventes;* the large have three parallel muscular bands upon their surface. The intestines admit of separation into three coats: the external, membranous or peritonæal; the middle coat, muscular; and the inner one, villous. They are attached to the body by the mesentery. The structure of the intestinal canal in different animals is wonderfully adapted to its required functions, dependent upon the nature of their food and other circumstances. Of these peculiarities the principal are adverted to under the titles of the animals in which they occur.

INTONA'TION. (Lat. in, and tonus, *a tone.*) In Music, the act of sounding with the voice the consecutive notes of the scale, or in any other given intervals. To do this correctly is the first qualification of a good singer. It is scarcely practicable without the assistance of a good ear, as well as a reference to some common idea, such as the key or mode wherein a piece is written. From the word *tone*, sometimes used in a sense almost identical with that of *key*, the word has its origin. The musical definition of this word in Todd's edition of *Johnson's Dictionary*, is absurdly given as "the act of singing together."

INTRA'DOS. The interior and lower line or curve of an arch. The exterior or upper curve is called the *extrados*. *See* Arch.

INTRE'NCHMENT. In Fortification, any work that fortifies a post against the attack of an enemy. It most usually denotes a ditch or trench with a rampart.

I'NTROIT. (Lat. introitus, *entry.*) In Ecclesiastical Antiquities, the verses chaunted or repeated at the first entering of the congregation into the church; a custom as old as the fourth century: called "ingressa" in the Ambrosian Ritual. (*Palmer*, *Origines Liturgicæ*, ii. 19.)

INTRO'RSES. (Lat. introrsum, *inwards.*) Turned inwards. A term used in describing the direction of bodies to denote their being turned towards the axis to which they appertain; thus, in most plants the anthers are introrse, being turned towards the style.

INTRU'SION. (Lat. intrudo, *I thrust upon.*) In Law, a species of injury to freehold property. It arises when a stranger intrudes between the death of tenant for life or years and the entry of the heir of a remainder-man or reversioner expectant on the estate for life or years, who had died previous to the decease of such tenant for life or years. Writ of intrusion lies only for a party who has the remainder or reversion in fee: remainder-man in tail has remedy by formedon. *See* Fee-Tail, Formedon.

INTUI'TION. (Lat. intueor, *I look into.*) In Philosophy, any act of the mind by which a truth is *immediately* perceived, and as it were *beheld*, without any previous process of analysis or ratiocination. Such, according to Kant, are the fundamental propositions of geometry; as, that "two straight lines cannot inclose a space," &c.

I'NTUSSUSCE'PTION. (Lat. intus, *within*, and susceptio.) In Anatomy, a term applied to the folding or passing of one portion of intestinal canal into another.

I'NULIN. A white powder deposited by a decoction of the roots of the *Inula helenium* or elecampane. In its chemical properties it appears intermediate between gum and starch.

INUNDA'TION. (Lat. in, and undo, *a wave.*) In Agriculture, lands which are overflowed by water from natural causes uncontrolled by art, are said to be inundated: when in consequence of the exercise of art and skill, the result is termed irrigation.

INVALI'DS. (Lat. invalidus, *weak.*) Those soldiers or sailors who, either on account of wounds or length of service, are admitted into hospitals, and there maintained at the public expense. The practice of making provision for soldiers worn out or disabled in the public service dates

from high antiquity. The liberality of Pisistratus to the Athenian soldiers is known to every scholar; and the history of ancient Rome is replete with instances of the veterans of the legions being rewarded with grants of land. It must be admitted, however, that in ancient times such recompences had not their origin in that high philanthropic feeling by which the moderns are actuated in making provision for military and naval invalids; for they were granted only after victory, and emanated more from individual power or favour than from any general or established principles of benevolence. In modern times there is no civilised country without institutions for the maintenance of invalids; but the most magnificent are, without question, the Greenwich and Chelsea hospitals in England, and in France the Hôtel des Invalides.

INVE'NTION. (Lat. invenire, *I find.*) In the Fine Arts, the choice and production of such objects as are proper to enter into the composition of a work of art. "Strictly speaking," says Sir Joshua Reynolds, "invention is little more than a new combination of those images which have been previously gathered and deposited in the memory: nothing can come of nothing: he who has laid up no materials can produce no combinations." Though there be nothing new under the sun, yet novelty in art will be attainable till all the combinations of the same things are exhausted, — a circumstance that can never come to pass.

INVE'NTION OF THE CROSS. A festival celebrated May 3d, in the Roman Catholic church, in honour of the finding of the cross on which our Saviour was executed. The search was instituted by order of St. Helena, mother of the Emperor Constantine, A. D. 326; and the cross, according to St. Cyril, was found among the ruins of Mount Calvary.

I'NVENTORY. (Lat. invenio, *I find.*) A catalogue of movables. See EXECUTOR.

I'NVERSE METHOD OF FLUXIONS. The method of finding the *fluents* of given fluxional expressions. It is the same with the integral calculus.

I'NVERSE METHOD OF TANGENTS. The method of finding the curve whose tangents are lines drawn according to some determinate law, or which fulfil some given condition. For example, suppose rays of light issuing from a luminous point to fall on the concave surface of a sphere, and to be thence reflected; the problem may be proposed to determine the nature of the curve to which all the reflected rays in any given plane are tangents. Problems of this kind require the application of the integral calculus; and hence the method by which they are solved is called the *inverse* method of tangents, as opposed to the *direct* method, viz. that of finding the tangent to a curve which is performed by the differential calculus.

I'NVERSE PROPORTION, in Algebra and Arithmetic, is the application of the rule of three, or proportion, in a reverse or contrary order. This is usually described by saying that less requires more, or more requires less. Thus, the question, "if 20 men cut down 3 acres of corn in a given time, how many men will be required to cut down 6 acres in the same time?" belongs to the direct rule, the quantity of work done being directly proportional to the number of men employed; but the question "if 20 men do a piece of work in 6 days, in what time will 40 men perform the same?" is one of inverse proportion, for more men will do the work in less time, or the number of men required is inversely as the time. The question may be stated in this manner, $\frac{1}{20} : \frac{1}{40} :: 6$; and the answer is 3.

I'NVERSE RATIO. The ratio of the reciprocals of two numbers. See INVERSE PROPORTION.

INVE'RSION. (Lat.) In Rhetoric and Philology, the transposition of words out of their natural order. Every language has a customary arrangement of its own to regulate the order of succession in which words forming part of the same sentence, member, or proposition follow each other. On the other hand, there is undoubtedly a natural or philosophical order of words following each other in the same analytical succession in which ideas present themselves to the mind, varied occasionally by that produced by the succession of sentiments or emotions; and as in every language many customary phrases, if not the general arrangement of the words, are contrary to this primitive order, every language has customary inversions of its own. Deviations from the *customary* order of words are more commonly called transpositions; but each word has, of course, a relative and somewhat arbitrary signification. As an instance of ordinary inversion, it may be observed that, according to the metaphysical or analytical order, the subject of a proposition precedes the predicate, being the first idea which presents itself to the mind. Thus, in the construction of a sentence containing a proposition (*see* LOGIC), "Solon is wise," or "Alexander reigns," we habitually follow the order of nature. But when a substantive and adjective in connection form part of a sentence, *i.e.* a subject or predicate, or a part of either, the substantive is that which seems naturally to present itself first to the mind; whereas in most modern languages it follows the adjective, while in the Greek and Latin its ordinary although not its necessary place was before it: "Who is a wise man?"—"Vir bonus est quis?" "The end of a long silence."—"Finis silentii diuturni." It is in general to be observed, that modern languages admit far less readily than ancient of transposition; but there are considerable differences in this respect between modern languages themselves. German admits much latitude, French very little. In our own language we are frequently able to vary the analytical order by following what may be termed the order of emotion, where a French writer could not do so: thus in the proposition "Great is Diana of the Ephesians," it would be impossible, in French, to give the force which is added to the expression by the transposition of the predicate to the beginning without violating the habitual rules of construction. A similar instance of inversion is to be found in the Swedish and some kindred languages, in which the article follows instead of preceding the noun.

INVERSION. In Music, the change of place between two notes of an interval; that is, placing the lower note an octave higher, or the higher note an octave lower.

INVE'RTEBRATES, *Invertebrata.* (Lat. in, priv.; vertebra, *a joint of the back-bone.*) The animals which are devoid of vertebræ, or an internal bony skeleton; and which include the Molluscous, Articulate, Nematoneurous, and Acrite sub-kingdoms. Lamarck's primary division of the animal kingdom into *Vertebrata* and *Invertebrata* corresponds with that proposed by Aristotle into *Enaima* and *Anaima.* It is, however, subject to the same objection as applies to most of the Dichotomous systems in Zoology; viz. that the two members of the division are not equivalent to each other. The *Invertebrata*, for example, contain three if not four primary divisions of the animal kingdom, each of which are equivalent to the *Vertebrata.*

INVE'RTED ARCH. In Architecture, one wherein the lowest stone or brick is the key-stone. It is used in foundations, to distribute the weight of particular points, such as A A A, over the whole extent of the foundation, and hence its employment is frequently of the first importance in constructive architecture.

INVE'STITURE. In Feudal Law, the delivery of a fief by a lord to his vassal, accompanied by peculiar ceremonies. (*See* FEUDAL SYSTEM.) The investiture of a bishop was, properly speaking, his endowment with the fiefs and temporalties of the see. Hence it became a subject of contest between the popes and emperors, and one of the principal grounds of the great quarrel of Guelfs and Ghibellines. It was conceded by the emperors to the Roman see in 1122; but the question was ended by a substantial compromise, which left the nomination in reality in the hands of the temporal prince in European monarchies under the Roman Catholic religion. (See *Hallam's Middle Ages; Raumer's History of the Hohenstauffen; Gieseler's Text Book of Ecclesiastical History*, vol. ii.; *Mosheim's Eccl. History.*)

INVOCA'TION (Lat. invoco, *I call upon*), in Literature, signifies, in a general sense, an address at the commencement of a poem, preferred to the Muses or some other Being supposed capable of giving inspiration. Thus, while the ancient poets generally addressed their invocations to some particular muse or divinity, Milton invokes the "Heavenly Muse" and the "Holy Spirit;" and, in his *Henriade*, Voltaire calls to his aid "auguste Verité." For the chief rules of poetical invocation see the *Dict. de Richelet*, and the *Dict. de la Conversation.*

INVOCA'TION OF SAINTS. In Theology. According to Protestant writers, the veneration of saints and martyrs increased rapidly throughout the 4th century; but their *invocation* as intercessors with the Divinity did not generally commence much before the 5th. (See *Mosheim*, ii. 32. 102. ed. 1826, transl.; *Gieseler*, i. 283. transl.) The followers of Origen are said to have been the first "who apostrophised the martyrs in their sermons, and besought their intercession." Prayers *for* the saints among other departed spirits were discontinued about the 5th century. on the principle laid down by Saint Augustine, "Injuria est pro martyre orare, cujus nos debemus orationibus commendari." *See* MARTYRS, SAINTS.

I'NVOICE. A list or account of goods or merchandise sent by merchants to their correspondents at home or abroad, in which the peculiar marks of each package, with their value, customs, provision, charges, and other particulars, are set forth. (See *Com. Dict.*)

INVOLUCE'LLUM. (Lat.) In Botany, the secondary involucrum surrounding one of the umbellules of an umbelliferous flower, or the florets of a capitulum.

INVOLU'CRUM. (Lat.) In Botany, a term having three significations: —

1. A ring of bracts surrounding one or many flowers.
2. In describing ferns to denote the superincumbent cuticle covering the sori.
3. In describing *Equisetaceæ*, to denote the cases of reproductive organs.

I'NVOLUTE, in the Higher Geometry, is a curve conceived to be described by the extremity of a string unwinding itself from the arc of another curve about which it has been lapped. All curves, in which the curvature is neither infinitely great nor infinitely small, may be generated in this way by the evolution of a thread from another curve, which is called the *evolute* of the new curve. *See* EVOLUTE.

The method of generating curves by evolution is a geometrical theory invented by Huygens, and given in his *Horologium Oscillatorium*, where he shows that the involute of a cycloid is another cycloid equal to the original one; and he applies this property to the practical purpose of causing a pendulum to vibrate in the arc of a cycloid; in which case, by another remarkable property of that curve, the vibrations are performed in equal times, whether the arc of vibration be great or small.

INVOLU'TION, in Arithmetic and Algebra, is the method of finding any power of an assigned quantity; and is the reverse of *evolution*, which denotes the method of finding the root of any quantity, which is considered as a power of that root.

The successive powers of any quantity are found by the continual multiplication of the quantity itself. Thus, taking the number 5, we have

$5 = 5^1$, the first power or root,
$5 \times 5 = 5^2$ or 25, the second power or square,
$5 \times 5 \times 5 = 5^3$ or 125, the third power or cube,

and so on; whence we see that the number of multiplications required to raise a number to any power is one less than the number of the index by which the power is expressed.

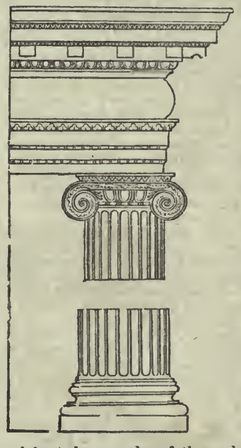
In algebra, simple quantities are involved by multiplying the exponents of the symbols by the index of the power required, and raising the coefficients to the same power. Thus the cube or third power of $2\,a^2\,x$ is $8\,a^6\,x^3$. Compound quantities are involved in the same manner as numbers by a continual multiplication of the quantity itself, or more generally and expeditiously by means of the binomial theorem.

I'ODINE. (Gr. ιωδης, *violet-coloured.*) A substance discovered in 1812 by M. Courtois of Paris. In this country it is usually prepared from kelp, which is lixiviated with water; and when the crystallizable salts have been separated, the mother liquors are mixed with sulphuric acid and black oxide of manganese. On the application of heat the iodine rises in the form of a dense violet-coloured vapour, which by condensation forms steel-grey crystals looking like micaceous iron. The specific gravity of iodine is between 4 and 5; when dry it fuses at 227°, and boils and evaporates in purple fumes at 345°. When heated with water it distils over at temperatures below 212°. The specific gravity of its vapour is about 8·7, so that 100 cubic inches would weigh nearly 270 grains. Iodine belongs to the electro-negative supporters of combustion. It has an acrid taste, and a peculiar odour somewhat like that of chlorine. It is an irritant poison; but in small doses, and cautiously administered, it has occasionally been of great service in certain forms of glandular disease. It is very sparingly soluble in water, of which it requires 7000 parts for its solution; the colour of the solution is brown: it dissolves copiously in alcohol and in ether, and forms dark-brown liquids. It possesses strong powers of combination, forming, with the metals, a class of compounds called *iodides;* with oxygen it forms the *iodic acid*, and perhaps one or more oxides. Combined with hydrogen, it forms the *hydriodic acid*. Its equivalent number is 126, and that of the hydriodic acid 127. Starch is a characteristic test of the presence of free iodine, forming with it a compound of a deep blue colour. It is so delicate that a solution of starch dropped into water containing less than a 400,000th part of iodine, is tinged blue by it; but the solutions must be cold, for the blue compound is soluble in hot water. The great consumption of iodine is in medicine; it is employed in its pure state, and in the form of *iodide of potassium*, which is obtained by dissolving iodine in a solution of pure potash, evaporating to dryness, and fusing the residue. This compound is sometimes called *hydriodate of potash.*

I'OLITE. (Gr. ιον, *violet.*) A mineral of a violet blue by transmitted light; it occurs crystallized, and in small grains and rolled masses.

IO'NIC DIALECT, the most euphonious of the four written varieties of the Greek language, was spoken by the inhabitants of the Ionian Islands, and in their colonial possessions in Asia Minor. It was originally the same as the Attic dialect, at least they boasted of a common origin; but from the extensive commercial intercourse of the Ionians with the eastern nations, their language gradually imbibed a portion of Asiatic effeminacy, which at length became its chief characteristic, forming a striking contrast to that combination of strength and harmony which distinguished the dialect of Attica. The chief writers in the Ionic dialect are Herodotus, Hippocrates, and Galen: but it is in the writings of the first that the most complete specimen is to be found.

IO'NIC ORDER. One of the five orders of architecture, whose distinguishing feature is the volute of its capital. In the Grecian Ionic the volutes appear the same in the front and rear, being connected on the flanks by a baluster-like form: through the external angles of the capitals of the corner columns, however, a diagonal volute is introduced. The Romans gave their Ionic four diagonal volutes, and curved the sides of the abacus. The Greek volute continues the fillet of the spiral along the face of the abacus, whereas in the Roman its origin is behind the ovolo. In some Grecian specimens a neck is added below the echinus, sculptured with flowers and leaves. The height of the column is about nine diameters, and the base varies considerably in different examples. When a pedestal is used it is somewhat higher and more ornamented than the Doric pedestal. The Greeks usually made the entablature of this order very simple. The architrave has two fasciæ, the frieze plain, and the cornice of few subdivisions; but the modern Ionic is seldom with less than three fasciæ, the frieze is often cushioned, and the cornice is deeper and not unfrequently modillioned, its profile being much varied. The dentil is also much used in the bed mouldings. The shaft is cut with twenty-four flutes separated by fillets. Some of the most celebrated examples of the order are the temple on the Ilyssus, of Minerva Polias at Athens and Priene, Bacchus at Teos, Apollo Didymæus at Miletus, Fortuna Virilis and the Coliseum at Rome. The profile above given is after Palladio.



IO'NIC PHILOSOPHERS. The earliest among the Greek schools of philosophy. Speculation arose in Greece, as elsewhere, in the attempt to discover the laws of outward phenomena, and the origin and successive stages of the world's development. Such an attempt, it is needless to say, must at first have been extremely rude. To the student of philosophical literature, however, no such undertaking, however unsuccessful, can possibly be otherwise than interesting; and in this instance in particular we are able to discover manifest traces of that liveliness of thought and systematic spirit which distinguish the later Greek speculations. The fathers of the Ionic school were Thales and his disciple Anaximenes. They were succeeded in the same line of thought by Diogenes of Apollonia, and Heraclitus of Ephesus. The characteristical mark which distinguishes the speculations of these thinkers is the endeavour to refer all sensible things to one original principle in nature. The two first named were satisfied with a very simple solution of the problem. Water with the one, and air with the other, were made the original materials out of which all things arose, and into which they were finally resolved. In their successors the germs of a more philosophical doctrine are apparent. They retain, indeed, the simplicity of an original element; but the *air* of Diogenes and the *fire* of Heraclitus are apparently only sensible symbols, which they used only in order to present more vividly to the imagination the energy of the one vital principle which is the ground of all outward appearances. It would indeed be a mistake to regard these philosophers as *materialists*. The distinction between objective and subjective, between a *law* operating in the universe and the corresponding apprehension of that law by reason, however obvious it may seem at the present day, seems to have required the deep meditation of numerous powerful thinkers to bring it into clear consciousness.

That the two things were confounded by Heraclitus is evident from his attributing to this universal fire the attributes of a universal reason, — the source at once of the order in the world, and of the insight into that order possessed by man. Notwithstanding this confusion, the discovery is due to him of the important truth, that "reason is common to all men." — that the ultimate principles of science derive their validity from their univer-

sality; a truth the value of which is not diminished by our finding it combined with the physical hypothesis to which we have alluded.

The philosophers enumerated above may be considered as forming one division of the Ionic school. They agree in regarding the universe as the result of the spontaneous evolution of a single principle or power; and all sensible things as modifications of this principle, real only in reference to their ultimate ground. But we meet also with a class of thinkers in whom the contrary tendency prevailed. Anaximander (B.C. 590) and Anaxagoras, the master of Pericles, agree in this respect, that they consider the world to be made up of numberless small particles, of different kinds and of various shapes, by the change in whose relative position all phenomena are to be accounted for. This hypothesis is combined by Anaxagoras with a Supreme Reason, the author of all that is regular and harmonious in the disposition of these elementary atoms. Anaxagoras may indeed be considered as the first philosopher who clearly and broadly stated the leading distinctions between mind and matter. For a statement at once luminous and accurate of the leading peculiarities of this philosopher's doctrines, and those of his predecessors, the reader is referred to Bishop Thirlwall's admirable *History of Greece*, vol. ii. chap. 12. The student who wishes for more minute information may consult Brandis and Ritter's Histories of Philosophy, of the latter of which a translation has appeared at Oxford. (See especially book iii.) See also a collection of the Fragments of Heraclitus in *Wolf and Buttman's Museum of Antiquities*, Bd. I. stck. 3; and the *Memoires de l'Ac. des Inscriptions*, vol. xvii.

IPECA'CUA'NHA. The root of the *Cephaelis ipecacuanha*. This important article of the *Materia Medica* is the produce of South America; it is in short wrinkled pieces, covered with a grey or brownish grey epidermis, and having a central woody fibre, surrounded by a pale grey cortical part, in which its virtue resides. It has a nauseous odour, and a repulsive bitterish taste. It is difficultly reducible to powder, and the dust which it throws off whilst under the process of pulverization is apt to excite great irritation of the respiratory organs. From fifteen to twenty grains of powdered ipecacuanha root taken in an ounce of water is one of the safest and surest *emetics;* in doses of from one to three or four grains it is a *nauseant;* and in smaller doses, repeated every four or six hours, as from a fourth of a grain to a grain, it is expectorant and diaphoretic. It contains from twelve to sixteen *per cent.* of *emetin*, to which its medical activity is referable. When long boiled with water its emetic power is diminished, but the decoction is aperient. There are several varieties of ipecacuanha, some of which arise from modifications of soil and climate; others appear to be the roots of distinct plants.

IRIDA'CEÆ. (Iris, one of the genera.) A natural order of herbaceous Endogens inhabiting the Cape and some other places. It differs from *Amaryllidaceæ* essentially in being triandrous, with the anthers turned outwards; from *Orchidaceæ*, in not being gynandrous; and from *Zingiberaceæ* and *Marantaceæ*, in having three perfect stamens. The species are more remarkable for their beautiful flowers than for their utility. The substance called saffron is the dried stigmata of the *Crocus sativus*. The various species of *Iris*, *Ixia*, *Gladiolus*, *Tigridia*, *Crocus*, &c., are among the favourite flowers of the gardener.

IRI'DIUM. (Lat. iris, *the rainbow*, in consequence of the variety of colours exhibited by its solutions.) A metal discovered by Dr. Wollaston, associated with the ore of platinum. It is grey, brittle, very infusible, and its specific gravity is about 18·6. It forms several oxides and chlorides, and combines readily with carbon.

IRIS. (Gr. Ἶρις.) In Grecian Mythology, the personification of the rainbow. She also performed the duties of a messenger to Jupiter and Juno.

IRIS. A name for the rainbow. *See* RAINBOW.

IRIS. In Anatomy, the anterior part of the *choroid* coat of the eye, with its central perforation, called the *pupil;* the posterior part or back of the iris is called the *uvea*. The term iris is applied to that part of the eye on account of its various colours. *See* EYE.

IRI'TIS. Inflammation of the iris of the eye.

I'RON. A metal known from remotest antiquity, of a peculiar grey colour, and possessing when polished much lustre. It is not very malleable, but extremely ductile, and very tenacious. At common temperatures it is hard and unyielding; but at a red heat it is soft and pliable, and at a high red heat it may be united to another piece equally heated by hammering them together: this process is called *welding*. The specific gravity of pure iron is about 7·7. Its texture is fibrous; it is very difficult of fusion, requiring for that purpose the highest temperature of a wind furnace. It is attracted by the magnet, and is itself susceptible of being rendered magnetic, a property possessed by no other metal except nickel. Another remarkable circumstance in the history of iron is, that it has only hitherto been found *native* (that is, in its pure metallic state), in stones and masses apparently of *meteoric origin*; for the accounts of other forms of native iron are doubtful. In combination with oxygen and with sulphur, and occasionally with other substances, it is very abundant in the mineral world, and is found in small quantities in many animal and vegetable substances. Those minerals which contain iron so combined as to be employed as sources of the metal for the purposes of the arts and manufactures are more exclusively termed the *ores of iron;* and among them the different *oxides of iron*, and the *carbonate*, either pure or in combination with various earthy matters, forming the *clay ironstone* of our coal districts, are the most important. The red oxide, and the black oxide (ferroso-ferric oxide of Berzelius), are also valuable ores. The finest Swedish iron is chiefly procured from the purer oxides, and especially from the native black oxide or *magnetic iron ore*, and is reduced by charcoal; in this country clay ironstone is chiefly resorted to, and it is reduced by coke.

There are two kinds of iron, known in commerce under the names of *cast* and *wrought* iron. There are also two principal varieties of cast iron, distinguished by the terms *white* and *grey*. The first is very hard and brittle, and when broken of a radiated texture: grey iron is softer and less brittle, and may be bored and turned in the lathe. The varieties of cast iron are also very different in their chemical composition; some much purer than others: they often contain traces of sulphur, phosphorus, silicium, calcium, manganese, and always more or less oxide of iron and carbon. The purer kinds of cast iron, which are chiefly carburets of iron, may be converted into malleable iron by heating them, surrounded by pure oxide of iron, by which the carbon is gradually extracted in the form of carbonic oxide: it is thus that horse shoes, and other articles, such even as knives, scissors, snuffers, &c., are fashioned by casting, and afterwards purified by the curious process just noticed. The cast iron manufactured in this country is converted into bar or malleable iron, chiefly by a process called *puddling*, which consists in subjecting it to the continued action of heat in a reverberatory furnace, where as soon as it melts it is stirred about till it gradually becomes less and less fusible, and at length grows tough and pulverulent. During this part of the process the mass heaves and emits a blue flame, in consequence of the burning off of some of its impurities; the fire is then so far increased as to agglutinate the metal into a mass, which, intensely heated, is transferred to a powerful rolling mill; as it passes successively through the rollers, a large quantity of impurities, chiefly its earthy ingredients, in combination with oxide of iron, are squeezed out in the form of a fluid slag, and the iron is extended into malleable bars; these are cut into pieces, placed in parcels or faggots in a very hot furnace, and again hammered or rolled into bars; they thus become more tough, flexible, and malleable, but much less fusible, and may now be considered as nearly pure iron.

When iron is heated red-hot with the free access of air, it undergoes a slow combustion; that is, it combines with the oxygen of the air, and is converted into a black fusible substance, as is seen when a bar of white-hot iron is beaten upon the smith's anvil, the scales which fly off in brilliant combustion producing the *black oxide of iron*. When a thin piece of iron is introduced red-hot into oxygen gas, or when a current of oxygen is directed upon it, it burns with great splendour, throwing off brilliant sparks, and becoming rapidly oxidized. When this black oxide or when metallic iron is exposed to air and moisture, or heated for a long time in contact of air, it becomes converted into a *brown oxide*, familiarly known as *rust of iron*. When iron is acted upon by dilute sulphuric acid, it decomposes the water of the acid, and becomes converted into a *protoxide of iron*, which is taken up by the acid, and yields a green solution; from which, on evaporation, green crystals may be obtained of *protosulphate of iron*, commonly known as *green vitriol*.

It appears from the analyses of these compounds that the number 28 may be assumed as the equivalent of iron, and that the protoxide (existing in green vitriol and in the protosalts of iron generally) is constituted of 1 atom of iron $= 28$, and 1 of oxygen $= 8$, and is consequently represented by the equivalent number $28 + 8 = 36$; that the brown or red oxide, or peroxide of iron, consists of 28 iron and 12 oxygen, and is represented by the equivalent 40; and that many of the native oxides, and, generally speaking, the scales of iron, are a definite combination of the above protoxide and peroxide, containing 2 atoms of protoxide and 1 of peroxide.

The most efficient tests of the presence of iron in water, and in solution generally, are the tincture of galls, which produces a purple or dark blue tint in liquids containing very minute proportions of iron, or a black precipitate where the metal is more abundant; and the ferrocyanate of potash, which produces Prussian blue under similar circumstances.

Of the combinations of iron, *steel* is, perhaps, the most important. It is formed by heating pure iron in contact

with charcoal, and is a compound of iron with a small proportion of carbon. *See* STEEL.

The manifold uses of this valuable metal are too well known to require being pointed out; and no one can doubt that its discovery has done more perhaps than any thing else to facilitate the advance of mankind in the career of improvement. "It accommodates itself," as Dr. Ure has observed, "to all our wants, our desires, and even our caprices; it is equally serviceable to the arts, the sciences, to agriculture and war; the same ore furnishes the sword, the ploughshare, the pruning hook, the needle, the graver, the spring of a watch or of a carriage, the chisel, the chain, the anchor, the compass, the cannon, and the bomb. It is a medicine of much virtue, and the only metal friendly to the human frame. The ores of iron are scattered over the crust of the globe with a beneficent profusion, proportioned to the utility of the metal; they are found under every latitude, every zone, and in every mineral formation; and they are disseminated in every soil. But though iron is the most common of the metals, it is by far the most difficult to obtain in a state fit for use; and the discovery of the method of working it seems to have been posterior to the use of gold, silver, and copper. It would be vain to attempt to investigate the steps by which men were at first led to practise the processes required to fuse it, and render it malleable; but that the invention of these curious arts is of a very early date is evident from the fact that Tubal Cain, but a short time after the creation, was "an instructor of every artifice in brass and iron." In most instances, the profane historians of antiquity have either attributed the discovery of iron and its uses to their divinities, or they have deified those to whom they supposed they owed the blessings of so valuable a discovery.

At what period Iron began to be made in this country there is no means of ascertaining; but there is authentic evidence to show that iron works were established by the Romans in the Forest of Dean in Gloucestershire, and in other parts of the kingdom. (*Pennant's Wales*, vol. i. p. 89. ed. 1810.) They were also established at an early period in Kent and Sussex; but it was not till after the celebrated invention of Lord Dudley in 1619, by which pit coal was substituted for timber in the smelting of iron ore, that a great impetus was given to the working of this valuable mineral; an invention which, though interrupted and clogged for a time by the devices of an ignorant rabble, at last established for itself a sure footing both in this and in every other European country. From 1740 (the period at which Lord Dudley's invention became generally adopted) the progress of the manufacture has exceeded the most sanguine expectations; and though we have no means of ascertaining the exact quantity produced, the subjoined estimates will show at once the value of the manufacture, and the unexampled rapidity of its growth during the last century. In 1740, the quantity amounted, in England and Wales only, to 17,000 tons; in 1750, to 22,000; in 1788, to 68,000; in 1796, to 125,000; in 1806, to 250,000; in 1820, to 400,000; in 1827, to 690,000; and in 1840, to upwards of 1,000,000 tons.

IRON PYRITES. *Yellow sulphuret of iron.* A bisulphuret of iron, composed of 28 iron + 32 sulphur. It is a very common and abundant ore of the metal; hitherto it has only been used for the production of sulphate of iron, or *green vitriol;* but attention has lately been turned to it as a source of sulphur.

I'RONY. (Gr. *εἰρωνεία;* from *εἴρων, a dissembler.*) In Rhetoric, the quality of style and of sentiment which Aristotle designates by the term *εἰρωνεία*, is somewhat different from that which bears the same title in modern phraseology, being, in fact, only a subdivision of it. Eironeia, in his sense of the word, is an artful representation of qualities or things as less than they really are. Thus, among the various characters of the human mind as given by him, the *εἴρων* (iron) is one who affectedly conceals or depreciates his own good qualities. Quintilian gives to rhetorical irony a far more general sense, terming it *diversiloquium*, or the use of expressions contrary to the thoughts of the speaker. He also distinguishes it into two species, treating it as a trope or figure of speech where the opposition of thought to language extends only to a few words; a figure of thought, where it extends to a whole passage or discourse. The Socratic irony is employed in argument when one speaker affects to take the positions of the other for granted, in order adroitly to lead him into self-contradiction or obvious absurdity. In the ordinary sense, irony is a more delicate species of sarcasm, by which praises are bestowed where it is intended to convey the opposite sense of disapprobation; or assent is notified where the real object is to express dissent.

IRRADIA'TION, in Physics and Astronomy, is the phenomenon of the apparent enlargement of an object strongly illuminated. The impression produced by light on the retina appears to be extended, though to an extremely small distance, round the focus of the rays concentrated by the lenses of the eye. Hence the image of a star is never a point, but a disc having a sensible diameter, and larger in proportion as the light is more intense; and hence also the luminous part of the moon at her first quarter appears larger than the other. This effect, which is termed *irradiation*, results evidently from the very nature of the organ of vision.

IRRA'TIONAL. In Arithmetic and Algebra, a term applied to numbers or quantities of which the roots are incommensurable with unity, and therefore cannot be accurately extracted. Thus, the root $\sqrt{2}$ is irrational, because it cannot be expressed by any finite number. If the side of a square $= 1$, then $\sqrt{2}$ is its diagonal; and it is proved by elementary geometry that the diagonal of a square is incommensurable with its side. Irrational quantities are also called *surds*.

IRREDU'CIBLE CASE, in Algebra, is that particular case in the solution of a cubic equation in which Cardan's celebrated formula contains an imaginary expression, and therefore fails in its application. This circumstance occasioned great embarrassment to the early analysts, and all the efforts of their successors to overcome the difficulty in a direct way have proved unsuccessful. In order to show in what it consists, let the proposed cubic equation be $x^3 + a\,x + c = 0$; then, by Cardan's rule, we have

$$x = \left(-\tfrac{1}{2}c + \sqrt{\tfrac{1}{27}a^3 + \tfrac{1}{4}c^2}\right)^{\frac{1}{3}} + \left(-\tfrac{1}{2}c - \sqrt{\tfrac{1}{27}a^3 + \tfrac{1}{4}c^2}\right)^{\frac{1}{3}}.$$

Now, if in this expression a is negative, and $\frac{1}{27}a^3$ is greater than $\frac{1}{4}c^2$; then $\frac{1}{27}a^3 + \frac{1}{4}c^2$ will be a negative quantity, and consequently the extraction of its square root will be impossible, or the expression $\sqrt{\frac{1}{27}a^3 + \frac{1}{4}c^2}$ will be imaginary. But it is known from the theory of equations that every cubic equation must have at least one real root; and it is a circumstance not a little remarkable that those cubic equations in which this imaginary expression occurs have not only one real root, but have all the three roots real.

It is possible to disengage the expression for the value of x from the imaginary quantities by expanding it by the binomial theorem; for the imaginary quantities, which will be the same in both the resulting series, will be positive in the one series and negative in the other; and therefore, on adding the series together, they will be eliminated. But the series which results from this addition will very rarely be convergent, consequently this method is of no use whatever. Various indirect methods of finding the roots have been proposed; the following is one of the simplest: —

Let $y^3 - q\,y = r$ be the proposed equation. Find in the trigonometrical tables an arc a whose natural cosine is $3\,r\sqrt{3} \div 2\,q\sqrt{q}$; then the three roots of the proposed equation are,

$$y = 2\sqrt{\tfrac{1}{3}q} \times \cos.\ \tfrac{1}{3}a,$$
$$y = -\,2\sqrt{\tfrac{1}{3}q} \times \sin.\ \tfrac{1}{3}(90^\circ - a),$$
$$y = -\,2\sqrt{\tfrac{1}{3}q} \times \sin.\ \tfrac{1}{3}(90^\circ + a).$$

These formula apply, whether r be positive or negative; but when r is negative, it is more convenient to choose the arc a such that its natural *sine* is $3\,r\sqrt{3} \div 2\,q\sqrt{q}$, and the three roots are then

$$y = 2\sqrt{\tfrac{1}{3}q} \times \sin.\ \tfrac{1}{3}a,$$
$$y = 2\sqrt{\tfrac{1}{3}q} \times \cos.\ \tfrac{1}{3}(90^\circ + a),$$
$$y = -\,2\sqrt{\tfrac{1}{3}q} \times \cos.\ \tfrac{1}{3}(90^\circ - a).$$

See the article "Algebra," by Professor Wallace, in the *Ency. Britannica.*

IRRE'GULAR CADENCE. In Music, one which does not end upon the essential chord of the mode in which a piece is composed. *See* CADENCE.

IRRIGA'TION. (Lat.) The art of watering lands artificially, and by means of surface drains or channels, as contrasted with watering by manual labour. In Britain, and in analogous climates, irrigation is almost exclusively applied to grass lands; but in warmer climates, such as those of Italy, Syria, India, &c., irrigation is considered as essential to the production of large crops in every description of field and garden culture. When any surface is to be irrigated, the supply of water which is to be used for this purpose is conducted to the highest part of that surface, and from thence it is led over it in open gutters, so as to run very slowly, and sink into the earth as it proceeds. As in general no very great extent of surface can be irrigated at once, different parts of a field or farm are irrigated in succession; and in countries where this practice is universal, it often happens that one source of of supply is common to two or more farms, the occupiers of which have it on alternate days. In the south of France and Italy, abundant crops cannot be produced without irrigation. Even the potatoe crop and madder are irrigated in the neighbourhood of Avignon; and in Tuscany wheat, maize, beans, turnips, and every other crop that can be sown in drills in the fields, is watered from artificial channels. The practice is as old as human civilization, and some of the first machines which we read of in history are those for raising water from the Nile for irrigating the lands on its banks. Water, in short, is to the agriculture of warm climates, what manure is to the

cultivator of temperate regions. It is not altogether a substitute for manure; but as in temperate regions water without manure would be of little use, so in warm regions manure without water cannot be rendered fit for being taken up by the roots of plants.

ISBRA'NIKI. In Ecclesiastical History, a name of the Russian sect of Raskolniks. (*Mosheim*, vol. v.)

I'SCHIUM. (Gr. ισχις, *the loin*.) So called from its proximity to the loin. It is one of the bones of the fœtal pelvis, and a part of the *os innominatum* in the adult.

ISCHU'RIA. (Gr. ισχω, *I retain*, and ουρον, *the urine*.) Retention of urine.

I'SINGLASS. A very pure form of *gelatine*, prepared from certain parts of the entrails of several fish. The best is derived from the sturgeon, and is almost exclusively imported from Russia, twisted up in rolls or formed into cakes, which are afterwards torn into shreds or cut into fine shavings in this country. Good isinglass should be free from smell and taste, and perfectly soluble in boiling water.

I'SIS. One of the chief deities in the Egyptian Mythology. It is difficult amidst the mass of contradictory assertions to ascertain the real origin and attributes of this divinity; for while the Egyptians themselves are said to have confined their worship chiefly to Isis and Osiris (quod vide), the Greek and Latin writers, though exceedingly discrepant in details, assert broadly that these two divinities included, under different names, the whole pagan mythology. It would be futile in this place to trace the attempt of the Greeks to identify Isis with Io, the daughter of Inachus, whom they represent to have been introduced into Egypt under the form of a cow, and in that shape worshipped by the inhabitants of the country. By the Egyptians themselves Isis was regarded as the sister or sister-wife of Osiris, who concurred with her in the endeavour to polish and civilize their subjects, to teach them agriculture, and several other necessary arts of life. Among the higher and more philosophical theologians she was made the symbol of Pantheistic divinity: see especially the remarkable passage at the end of the *Golden Ass* of Apuleius. By the people she was worshipped as the goddess of fecundity, and in her honour an annual festival was instituted which lasted seven days. The cow was sacred to her. She was represented variously, though most usually as a woman with the horns of a cow, and sometimes with the lotus in her head and the sistrum in her hand. Her priests were bound to observe perpetual chastity; but on her worship passing into foreign countries, her rites became merely a cloak for sacerdotal licentiousness, which at last reached such a pitch that they were prohibited at Rome; and Tiberius, in the hope of annihilating them for ever, ordered the images of the goddess to be thrown into the river. The worship of Isis, however, was afterwards revived, and furnished an ample theme for the indignant pen of Juvenal. The *Isiac Table* in the Turin Museum, which was so long supposed by the learned to represent the mysteries of Isis, "has been judged by Champollion to be the work of an uninitiated artist little acquainted with the worship of the goddess, and probably of the age of Hadrian." (*Creuzer's Mythol.; Plutarch's Treatise on Isis and Osiris*, &c. &c.; an Essay by De Montfaucon, *Hist. de l'Ac. des Inscr.* vol. xvi., which contains a summary of the Grecian learning on the subject; *Mem. de l'Ac. des Inscr.* xxxiv.; and *Quart. Rev.*, July, 1840.)

Isis. (*Isidos proclamos*, a marine plant, like coral, according to Pliny.) The name of a genus of jointed coral, in which the joints are composed of substance resembling horn.

I'SLAM, or ESLAM. The religion of Mohammed. The body of the faithful, and the countries wherein it is professed, are so termed by the Mohammedans. The original word is said to signify *submission to God*. All those who professed the true religion and the unity of God, before the arrival of Mohammed, are considered as comprised in the character and privileges of Islamism. The Mufti of Constantinople, or chief minister of religion in Turkey, bears the title of Sheikh-ul-Islam.

ISLAND. (Lat. insula.) A tract of land encompassed with water, whether of the sea, a river, or a lake; in contradistinction to *continent* or *terra firma*.

ISLANDS OF THE BLESSED. (Insulæ Beatorum, Fortunatæ Insulæ; Νησοι Μακαρων.) According to the Grecian Mythology, the Happy Islands, supposed to lie westward in the ocean, whither after death the souls of the virtuous were transported. In the early mythology of the Greeks, the Islands of the Blessed, the Elysian fields, and the infernal regions, were generally confounded with each other. *See* Elysium.

ISMAE'LIANS. A Mohammedan sect, who derived their name from maintaining the pretensions of Ishmail, the son of Jaafar, to the rank of Imam, to the exclusion of Moussa, who was adopted by that saint. They consequently rejected the claims of Moussa and the five subsequent Imams. The Ismaelians formed a secret association, founded in the 10th century of the Christian era by Abdallah, a Persian. From them originated the famous society of the Assassins. (*Taylor's Hist. of Mohammedanism*, p. 225.; *Mem. de l'Ac. des Inscr.* vol. xvii.; "Secret Societies of the Middle Ages," published in the *Library of Entertaining Knowledge*, 1837.)

I'SOCHROMA'TIC. (Gr. ισος, *equal*, and χρωμα, *colour*.) Having the same colours. In certain experiments with doubly refracting crystals, the decomposed light forms a double series of coloured rings or curves of different forms, arranged in a certain order, each curve in the one series having one corresponding to it both in form and colour in the other. The two curves or lines which have the same tint are called *isochromatic*. (See Herschel's Treatise on Light, in the *Ency. Metropolitana*.)

ISO'CHRONAL, or ISOCHRONOUS. (Gr. ισος, and χρονος, *time; performed in equal times*.) Two pendulums which vibrate in the same time are isochronal; or the vibrations of a pendulum in the curve of a cycloid are so, being all performed in the same time, whether the arc be large or small. *Isochronal lines* are those along which a heavy body descends with a uniform velocity.

ISO'DOMUM. (Gr. ισος, and δομη, *structure*.) In Ancient Architecture, a species of walling in which all the courses were the same height.

I'SOLATED. (Fr. *isolé*, from the Ital. isola, Lat. insula, *an island*.) In Electricity, a body is said to be isolated when it is surrounded by non-conductors, or bodies to which it cannot communicate its electric virtue, except by induction. Bodies may be isolated in various ways; by suspending them by means of silken cords; by placing them on a cake of wax, resin, or sulphur, or on a stand of glass or dry varnished wood, &c.

ISO'MERISM. (Gr. ισος, and μερος, *part*.) Compounds which contain the same elements in the same ratio, and yet exhibit distinct chemical qualities, are said to be *isomeric*. The cyanic and fulminic acids are isomeric compounds of nitrogen, oxygen, and carbon. The distinctions thus arising are probably referable to the different ways in which the same elementary atoms are gropued in the compound.

ISOMO'RPHISM. (Gr. ισος, and μορφη, *form*.) Substances which resemble each other in their crystalline forms, but differ in their component parts, are said to be *isomorphous*. Thus the phosphate and biphosphate of soda have the same form, or are *isomorphous*, with the arseniate and binarseniate of soda; and in regard to other bases, such as potash and ammonia, each arseniate has a corresponding phosphate possessed of the same form. In these cases there is necessarily an analogy in the atomic constitution of the compounds, which are observed to possess the same number of equivalents of acid, alkali, and water of crystallization, and differ in nothing except that the one series contains an atom of arsenic, and the other an atom of phosphorus.

I'SOPE'RIME'TRICAL FIGURES (Gr. ισος, and περιμετρον, *circumference*), are such as have equal perimeters or circumferences. The term isoperimetrical problems, in modern analysis, designates a very extensive and difficult class of problems, the solution of which requires the application of a peculiar analysis. The general problem is this: — Among all curves having the same length, to determine that of which some assigned property is a maximum or a minimum; for example, among all curves having the same perimeter, to find that which has the greatest area. This is the simplest question of the kind, and the curve to which the property belongs is proved by elementary geometry to be a circle.

In all isoperimetrical problems there are two conditions to be fulfilled: according to the first of which a certain property is to remain constant, or to belong to all individuals of the species; and according to the second, another property is to be the greatest or least possible. In the problems of this kind which first attracted the particular attention of mathematicians, the constant quantity was the perimeter of a certain curve; and hence the origin of the term, which is now applied to all problems indifferently in which the question is to find curves having a property of maximum or minimum, with or without the condition of equality of perimeters.

James Bernoulli was the first who discovered the true principles on which questions of this kind depend, and the circumstances which render the ordinary methods of maxima and minima inapplicable to them. The immediate subject of his researches was the problem of the Brachystochrone (see the term), or curve of quickest descent, celebrated in the early history of the calculus on account of the controversy to which it gave rise between the two brothers, James and John Bernoulli. The analysis of the former, *Analysis magni Problematis Isoperimetrici*, was published at Basle in 1701, and in the *Leipsic Acts* of the same year. Solutions were afterwards given by Taylor in his *Methodus Incrementorum*; by John Bernoulli in the *Memoirs of the Academy of Sciences* for 1718; and by Euler in the *Petersburg Memoirs*. Euler afterwards gave a complete and general solution of the problem in his *Methodus Inveniendi Lineas Curvas Maximi Minimive proprietate gaudentes*, a work of which Lagrange has said that there is perhaps no other which can be of more use

to those who wish to exercise themselves in the integral calculus. The method, however, which is followed in this work has been superseded by the invention of the *calculus of variations* by Lagrange; a most important branch of analysis, of which the subject of isoperimetrical problems is one of the most obvious applications. (Lagrange, *Leçons sur le Calcul des Fonctions*; Woodhouse, *On Isoperimetrical Problems*; Lacroix, *Traité du Calcul Différentiel et Intégral*; *Airy's Tracts*, &c.)

ISO'PODA. (Gr. *ισος*, and *πους*, *a foot*.) The name of an order of Crustaceans, comprehending those which have the legs all alike, and adapted only for locomotion and prehension.

I'SOPO'DIFORM. The larvæ of Saprophagous Hexapods are so called which have an oblong body, a distinct thoracic shield, and a vent provided with filaments or laminæ.

I'SOPYRE. (Gr. *ισος*, and *πυρ*, *fire*.) In Mineralogy, a silicate of alumina, lime, and peroxide of iron, found near the granite of St. Just, near Penzance in Cornwall. It is a black amorphous substance, occasionally variegated with grey or red spots or streaks, slightly translucent. Its specific gravity is about 3.

ISO'SCELES. (Gr. *ισος*, and *σκελος*, *leg*.) In Geometry, an isosceles triangle is that which has two equal sides. Among the properties of isosceles triangles, one is that the angles at the base are equal; and as the demonstration which is given of this proposition in *Euclid's Elements*, where it stands at the very commencement, is somewhat intricate and puzzling to beginners, the proposition has been called the *pons asinorum*.

ISOSTE'MONOUS (Gr. *ισος*, and *στημων*, *a stamen*), in Botany, in expressing the proportion that one part bears to another, denotes that the stamens are equal in number to the petals.

ISOTHE'RMAL. (Gr. *ισος*, and *θερμη*, *heat*.) In Physical Geography, *isothermal lines* are those which pass through those points on the surface of the earth at which the mean annual temperature is the same. *Isothermal zones* are spaces on opposite sides of the equator having the same mean temperature, and bounded by corresponding isothermal lines. On account of the irregular form and disposition of the continental masses, by which the climate of different places is greatly influenced, the isothermal curves are not parallel to the equator, excepting in the very low latitudes. According to Humboldt, the isothermal line which corresponds to the temperature of 32° of Fahrenheit passes between Ulea in Lapland, lat. 66°, and Table Bay on the coast of Labrador, lat. 54°. The isothermal line of 41° passes near Stockholm, lat. 59½°, and St. George's Bay, Newfoundland, lat. 48°. The line of 50° passes through the Netherlands, lat. 51°, and near Boston in the United States, lat. 42½°; that of 59° between Rome and Florence, lat 43°, and Raleigh in North Carolina, lat. 36°. In all these cases we see that the isothermal lines, in passing from the western side of the continent of Europe to the eastern coast of America, deviate very considerably towards the south; the deviation, in one case, amounting to 11½° of latitude. In passing over the American continent, they again recede to the northward; and in California, and to the north of that peninsula, along the western side of the continent, the annual temperature is nearly the same as under similar latitudes in the west of Europe. From the western to the eastern side of the old continent, the flexure of the isothermal curves and the diminution of the mean annual temperature under the same parallels are not less conspicuous. The isothermal line of 55° passes through Nantes, lat. 47°, and Pekin, lat. 39¼. Edinburgh and Kasan (in the east of Russia) have the same latitude; but the mean annual temperature of the former is 48°, while that of the second is below 38°. For the different causes which affect the parallelism of the isothermal lines, or which produce the differences of the mean annual temperature of places under the same parallel of latitude, see CLIMATE.

Humboldt gives the name of *isotheral lines* (*ισος*, and *θερος*, *summer*) to the curves passing through those places at which the mean summer heat is the same; and of *isochimenal* (*ισος*, and *χειμων*, *winter*) to those which pass through the places at which the mean temperature of winter is the same. The isotheral and isochimenal curves deviate much more from the parallels of latitude than the isothermal. The latitudes of places having the same winter temperature sometimes differ so much as 18° or 20°. The winter of Scotland is as mild as that of Milan. The mean temperature of the winter months at Edinburgh is about 38½°; of Kasan, under the same parallel, only 2°. The winter of Pekin is as rigorous as that of Stockholm. (*Humboldt's Fragmens Asiatiques*; *Murray's Geography*, Introduction.)

I'SSUANT. In Heraldry, a charge represented as issuing or coming up from another charge or bearing; also, a lion or other beast represented as rising from the bottom line of a chief.

I'SSUE. In Law, in the most ordinary senses of the word,—1. The points in dispute in a suit at law between two parties, ascertained by the pleadings, are termed the issues; and are either issues in law, to be determined by the court, or in fact, to be ascertained by a jury. In each form of action (*see* ACTION, PLEADING) there was formerly a formal trasverse, by which the whole or principal part of the allegations of the plaintiff in his declaration might be denied: this was termed the general issue. Since the adoption of the new rules of pleading (1834), there is now properly speaking no general issue; except in certain cases, where the privilege of giving special matter in evidence under it is given by statute. A *feigned issue* is a technical mode of trying some questions, supposing an imaginary wager. In the Scottish practice of trial by jury it is usual to put printed copies of the Issues into the hands of the jurors.—2. The legitimate offspring of a man.

ISSUE, in Surgery, is an artificial ulcer. It is commonly made by wounding or cutting the skin, and placing a pea upon it, which is pressed upon the part by a bandage.

I'STHMIAN GAMES. One of the four great national festivals of Greece; so called from their being celebrated on the Isthmus of Corinth. They were common to all the states, with the exception in this case of the Eleans, against whom a curse had been pronounced should they ever present themselves there. They were held near a temple of Neptune, the god who presided over them; and were celebrated every third year, according to some accounts, but others assign them a period of one or four years. The contests were the same as in the other sacred games (*see* OLYMPIC GAMES): the victors were crowned with garlands of pine leaves. (See *Potter's Grecian Antiquities*; *Wachsmuth's Historical Antiquities*, ii. 162. translation.)

I'STHMUS. In Geography, a narrow neck of land joining two continents, or a continent and peninsula. Thus, the Isthmus of Darien, joining North and South America; the Isthmus of Suez, connecting Africa with Asia.

ITALIAN ARCHITECTURE. *See* ARCHITECTURE.

ITA'LIC SCHOOL OF PHILOSOPHY, comprehends properly the Pythagorean and Eleatic systems taken together; but sometimes it is used as synonymous merely with the school of Pythagoras. Under the several heads will be found the chief features of these philosophical systems, which, comprising as they do all that can be said in reference to the Italic school, it would seem unnecessary in this place further to advert to. The Italic school has been so designated because its founder, Pythagoras, taught in Italy, spreading his doctrine among the people of Tarentum, Metapontum, Heraclea, Naples, &c.

ITCH. A disease of the skin, consisting in an eruption of minute itching vesicles, which are commonly rendered more inflamed and troublesome by scratching. They generally make their first appearance between the fingers, or about the bend of the wrist, and often spread to other parts of the body, especially where cleanliness is neglected. The itch is highly contagious, and is supposed to depend upon a minute insect burrowing in the skin; some have regarded the insect as a consequence, and not the cause, of the disease. The itch is cured by sulphur, which should be given internally, and applied externally in the form of ointment.

ITIHA'SAS. The two great heroic poems of the Hindoos, the *Ramayana* and *Maha Bharata*, are so called. They are of great antiquity; later, however, than the *Vedas*. Some, indeed, have attributed the latter poem to a period later than that of Alexander.

ITI'NERARY. (Lat. iter, *a journey*.) In Literature, a work containing notices or descriptions of the places and stations to be met with in pursuing a particular line of road; as, an Itinerary from Paris to Rome: or of the principal places and stations on the great roads throughout a country; as, Itinerary of France, Italy, &c. The Latin Itineraries which have been preserved to us consist merely of catalogues of stations; and are principally valuable to us because they contain the distance, in Roman miles, from one to another, and thus furnish us with assistance towards determining the actual site of each place mentioned.

I'TIS. This termination, added to the genitive case of the Greek name of an organ or part of the body, implies *inflammation* of that part; as, *gastritis*, inflammation of the *stomach*; *pleuritis*, of the *pleura*, &c.

I'TTNERITE. Named after Ittner. A rare mineral, which occurs massive and in rhombic dodecaedrons, of a grey or blueish colour. It consists chiefly of silica, alumina, and soda, together with some hydrosulphuret.

IU'LUS. (Lat.) A genus of Myriapodous insects, characterized as follows:—Antennæ with seven joints, slightly enlarged towards the end; mandibles two, thick, without palps, each divided into two by a middle joint; provided with imbricated teeth; an inferior lip formed by the confluence of two maxillæ; feet attached in double pairs to most of the joints; body long, cylindrical, capable of being contracted into a discoidal spire. The common gally-worm (*Iulus terrestris*) is an example of this genus.

I'VORY. The tusk of the male elephant. It is less

brittle than bone, and of a beautifully uniform texture, admitting of turning in the lathe and receiving a high polish. It consists of about 24 per cent. animal matter resembling horn, and 66 of phosphate, with a trace of carbonate of lime. The chief consumption of ivory in England is in the manufacture of handles for knives; but it is also extensively used in the manufacture of musical and mathematical instruments, chess-men, billiard-balls, plates for miniatures, toys, &c. Ivory articles are said to be manufactured to a greater extent, and with better success, at Dieppe, than in any other place in Europe; but the preparation of this beautiful material is much better understood by the Chinese than by any other people. No European artist has hitherto succeeded in cutting concentric balls after the manner of the Chinese; and their boxes, chess-men, and other ivory articles, are all far superior to any that are to be met with any where else.

The western and eastern coasts of Africa, the Cape of Good Hope, Ceylon, India, and the countries to the eastward of the Straits of Malacca, are the great marts whence supplies of ivory are derived; but the most esteemed come from Africa, being of a closer texture and less liable to turn yellow than those from the East Indies. The medium weight of a tusk is about 60 lbs., and the average importation for the three years ending 1838 was 5752 cwt., yielding a duty of 5752*l.*

I'VORY BLACK. The mixture of charcoal and phosphate of lime obtained by burning bone is sold under this name, and, like other forms of animal charcoal, is very effective in depriving certain substances of their colour.

JABI'RN. The name of a Grallatorial or wading bird belonging to the genus *Mycteria*. See that word.

JACAMA'R. A genus of Scansorial birds. *See* GALBULA.

JACA'NA. The wading birds of the genus *Parra* are so called. *See* PARRA.

JA'CCHUS. (Gr. *ιαχω, I cry aloud.*) A genus of Platyrrhine Quadrumana, or South American monkeys, with thumbs on the hind foot only; all the digits of the fore foot having the same direction, and being armed with narrow, curved, claw-like nails. The characters of the genus are, — upper middle incisors separated from and larger than the lateral ones; lower incisors elongated, narrow, and vertical, the lateral ones the longest; upper canine teeth conical, and of moderate size, but more developed than the lower ones. The species of *Jacchus* are few in number, and not very clearly defined; they are all of small size. The *Jacchus penicillatus*, which is remarkable for the radiated tuft of white hairs which projects in front of each ear, has bred in captivity in this country. It is a very delicate little animal, susceptible of cold, and provided with a long and bushy tail, which it wraps round its head and body when asleep or requiring warmth. Its food is of a mixed nature; but in the wild state the banana is said to be its principal and favourite nutriment.

JACK. In Mechanics, an engine for raising heavy weights.

Jack is also the name given to a machine in common use for turning a spit. The common roasting jack, or worm-jack, consists of a double set of wheels; a barrel, round which the chain attached to the weight or moving power is wound; a perpetual screw; and a fly, which secures a steady uniform motion. A multiplying wheel is usually added, in order that the weight may be longer in running down.

The *smoke jack* is used for the same purpose as the common jack, and is so called because it appears to be moved by the smoke of the fire. It is in fact moved by the ascending current of rarified air, which acts on a fan properly placed in the chimney. The motion may be obtained by various contrivances. Sometimes spiral flyers coiled about a vertical axis are employed, but more frequently a vertical wheel with oblique leaves like the sails of a windmill.

JACK, in Nautical language, is a flag or colours used in making signals. In the British navy, the Jack is a small union flag, composed of red and white crosses; in merchants' ships, this union is bordered by a red field.

JACK. A common name for the pike. *See* ESOX.

JACK, in Botany, is the name of the *Tsjaca* or *Actocarpus integrifolia*, a species of the bread-fruit tree, found in the Indian Archipelago.

JA'CKAL. (Ar. tschakkal; Fr. chacal.) A wild species of dog, the *Canis aureus* of Linnæus; of gregarious habits; hunting in packs; rarely attacking the larger quadrupeds, but supposed to indicate their presence to the lion by the piercing cries which the jackals set up in chorus while scenting their tracks; feeding on the remnants of the lion's prey, on dead carcasses, and the smaller animals and poultry. The jackal interbreeds with the common dog; its period of gestation is the same, and the hybrid progeny is fertile. The wild jackal emits a highly offensive odour, which is scarcely perceptible in the domesticated animal. Some are of opinion that the 300 animals, called foxes, between whose tails Samson is said to have put firebrands in order to destroy the crops of the Philistines, were jackals. The *Canis aureus* is abundant in the warmer parts of India and Africa, but is not found in the new world.

JA'CKDAW, or DAW. (*Corvus monedula*, Linn.) A common English bird, which frequents church steeples, old towers, and ruins, in flocks, where they build their nests: the female lays five or six eggs, paler and smaller than those of the crow. The daw may be readily tamed, and taught to imitate the sounds of words. Like other species of the crow genus, they have the singular habit of stealing and hiding glittering and metallic substances.

JACKS. Wooden wedges used in coal mines.

JACK SINKERS. Parts of a stocking frame.

JACK TIMBERS. In Architecture, those in a bay of timbers which, being intercepted by some other piece, are shorter than the rest: thus, in a hipped roof, each rafter which is shorter than the side rafters is called a *jack rafter*.

JA'COBINS. In French History, a political club, which bore a well-known part in the first revolution. It was first formed by some distinguished members of the First Assembly, particularly from Britanny, where revolutionary sentiments ran high. They took at first the name of Friends of the Revolution; but as at the end of 1789 they held their meetings in the hall of a suppressed Jacobin monastery in the Rue Saint Honoré, the name of Jacobins, at first familiarly given them, was finally assumed by themselves. The history of the Jacobin club is, in effect, the history of the Revolution. It contained at one time more than 2500 members, and corresponded with more than 400 affiliated societies in France. The club of the Cordeliers, formed by a small and more violent party out of the general body of Jacobins, was reunited with the parent society in June, 1791; but continued to form a separate section within its limits. The Jacobin club, which had almost controlled the first assembly, was thus, during the continuance of the second, itself divided between two contending parties; although the name of Jacobins, as a political party, is commonly given to that section which opposed the Girondists or less moderate in the club no less than in the assembly. After the destruction of the latter under the Convention, the club was again exclusively governed by the more violent among its own members, until the downfal of Robespierre. After that period it became unpopular; and its members having attempted an insurrection on behalf of the subdued Terrorists, Nov. 11. 1794, the meeting was dispersed by force, and the club finally suppressed. Some writers, such as Barruel (*Hist. du Jacobinisme*), have seen in the first formation of this and similar societies, the long-concocted operations of a conspiracy against legitimate government and religion throughout Europe. The Jacobins, and the other principal clubs of the Revolution, adopted all the forms of a legislative assembly. In the constitution of 1792, their legal existence was recognized. See the historians of the French Revolution, especially Carlyle, Mignet, and Thiers, for general views; Messrs. Buchez et Roux, *Histoire Parlementaire de la Rev. Française*, for the most complete series of details respecting the Jacobins and their meetings which has yet been made public.

JACOBINS. In Ecclesiastical History, the religious of the order of St. Dominic were so called in France, from the situation of the principal convent at Paris, near the Rue St. Jacques; also called *Frères Prêcheurs*.

JA'COBITES. In English History, that party which, after the Revolution of 1688, adhered to the dethroned monarch James I., and afterwards to his descendants. In Scotland and Ireland, where the revolution was not effected except with the assistance of arms, the Jacobite party formed one of the two great divisions of each nation; and although crushed in the latter country by conquest, they continued in the former to comprise a large proportion of the population until long after the last rebellion in 1745. But in England the revolution was effected at first with the consent of all parties; the adherents to the exiled monarch were silenced: yet, in a year or two, the Jacobite faction rose into strength, and continued to harass the government of William throughout his reign. "It seems undeniable," says Hallam (*Constitutional History of England*, vol. iii. p. 149.), "that the strength of the Jacobite faction sprung from the want of apparent necessity for the change of government." Its immediate cause, however, was to be found in the refusal of a portion of the bishops and clergy to take the oaths to the new government (*see* NONJURORS), which gave, as it were, a certain consistency and tangible ground of opposition to the friends of the dethroned monarch in general. At the same time many of William's chief advisers and officers maintained a secret correspondence with James II. at the French court, less from any attachment to his cause than with a view to secure their own interest in case of his return. After the death of James II. in France, and accession of Anne in England, the efforts of the party languished for

a time; but towards the close of her reign they revived, on the prospect of a change in the succession. We have now undeniable proofs, from the French archives, of a fact which had been long suspected, that Bolingbroke and Oxford, with others of Anne's Tory ministers, were in treaty with the son of James II., and either really or in pretence negotiating for his return. In 1715, on the arrival of George I., broke out the unsuccessful first rebellion in Scotland: its ill conduct and failure proved a considerable check to the hopes of the English Jacobites. Bishop Atterbury, the last of their bolder intriguers and adherents, was banished in 1722: after which time it is probable that no extensive conspiracy took place on their part. In Scotland, however, the party maintained its strength unabated, until the second rebellion of 1745, by its complete failure, put an end to its political existence. It is said that some of the party maintained a correspondence with Charles Edward, until his decease in 1787. The Cardinal of York, his brother, died in 1807; and it has been said that, by his death, the adhesion of the Jacobites, if any existed, was transferred to the reigning family as his next heirs. This, however, is a vulgar error; the royal house of Sardinia and other families intervening between the house of Brunswick and the crown of England, according to the strict rules of hereditary descent.

JACOBITES. In Ecclesiastical History, the monophysite Christians of Syria are so called, from Jacob Baradzi, who revived their belief and form of worship in that country and Mesopotamia, in the middle of the 6th century. Many unsuccessful attempts have been made at various times to unite them with the church of Rome. (*Gieseler's Text Book*, Transl., ii. 419., iii. 414, &c.) *See* MONOPHYSITES, EUTYCHIANS.

JA'COB'S LADDER. In Naval affairs, a rope-ladder with wooden steps or spokes.

JACOB'S STAFF. The same as *cross-staff*. An instrument used by surveyors in measuring heights and distances where expedition and little accuracy are required.

JACQUA'RD. A piece of mechanism applicable to silk and muslin looms for the purpose of weaving figured goods. The name is that of its inventor. (For a description of the loom, see *Ure's Dictionary of Arts and Manufactures*.)

JA'CQUERIE. In History, the name popularly given to a revolt of the French peasantry against the nobility, which took place while King John was a prisoner in England in 1356. *Jacques Bonhomme* was a term of derision applied by the nobles to the peasants, from which the insurrection took its name. It began in the Beauvoisis, under a chief of the name of Caillet, and desolated Picardy, Artois, and Brie, where savage reprisals were executed against the nobility for their oppressions. It was suppressed after some weeks by the dauphin and Charles the Bad, king of Navarre. A similar spirit in England produced not many years afterwards the rebellion of Wat Tyler. (See Mézeray, i. 838.; Froissart; Sismondi, *Hist. des Français*, vol. x.)

JADE. In Mineralogy, a synonyme of *nephrite*.

JAGUA'R. (*Felis onca*, Linn.) The largest and most formidable feline quadruped of the new world. It is marked with large dark spots in the form of circles, with a dark spot or pupil in the centre of each; it is generally pretty numerous in the neighbourhood of the large rivers where the capibara abounds, and preys chiefly on those large Rodents.

JA'LAP. So called from Xalapha in Mexico, whence it originally came. The dried root of the *Ipomæa jalapa*. This root occurs in irregular globular pieces of a dense and resinous texture: when reduced to powder it has a very peculiar and nauseous odour and taste. In doses of from five to twenty grains, jalap is a drastic purge: it is apt to gripe and nauseate.

JAMB. A Sea term; to squeeze tight. The opposite of jamb, applied to a rope, is *to render*.

JAMBS. (Fr. jambes.) In Architecture, the side or vertical pieces of any opening in a wall which bear the piece that discharges the superincumbent weight of such wall.

JA'MESONITE. A mineral named after Professor Jameson. It occurs crystallized and massive: it consists of sulphur, lead, and antimony.

JAMES, SAINT, OF THE SWORD, ORDER OF. A very ancient military order in Spain and Portugal. The reigning kings are grand-masters in those countries respectively. The orders in the two countries were disunited in 1288.

JA'NISSARIES, or JA'NIZARIES. (A corruption of the Turkish word *yeni tscheri*, new troops.) A celebrated militia of the Ottoman empire. The establishment of this corps has been usually attributed to Sultan Amurath I. in 1368; but the researches of Hammer (*History of the Ottoman Empire*, vol. i. p. 92.) carry it back to Orchan, the conqueror of Nicæa (1326). This new corps was blessed by a saint of that time, Hadji Bektash by name, who cut off a sleeve of his fur mantle and gave it them as a token; whence was derived the fur cap that remained their distinguishing characteristic. This irregular infantry long remained the chief military strength of the empire, and formed a kind of warlike republic within its limits. It was long supplied chiefly by the capture of young Christian slaves; and when under Mohammed IV. it began to be recruited principally from the children of the soldiers themselves, its power and importance gave signs of decay. Each regiment or oda of the Janizaries had its own soup kettle, which, in process of time, acquired a sort of prescriptive sanctity, and formed, as it were, the chief standard of the regiment; and the officers and other military functionaries drew their titles from their various supposed employments as cooks or kitchen servants. The militia of the Janizaries continued to retain a great influence in the empire itself long after it had ceased to be serviceable in the field against the armies of modern Europe. They controlled the sultans themselves, and, as it is alleged, presented a serious obstacle to all improvement, until in the year 1826 the late sultan, on the occasion of a mutiny, dissolved the whole corps, after a bloody struggle in his capital in which 20,000 of them were said to have perished; but the number is now thought to have been exaggerated. There was an official publication relating to the destruction of the Janizaries, which was translated into French (Paris, 1833). See also *Walsh's Residence at Constantinople; Duval, Deux Années a Const.* (1828); *Quarterly Review*, vol. xli.; and *Ed. Rev.* vol. l.; *Slade's Travels in Germany, Turkey, &c.* (1840).

JA'NSENISTS. A denomination of Roman Catholics in France, who followed the opinions of Jansen, bishop of Ypres, and formed a considerable party in the latter half of the 17th century. The Jansenists were Calvinistic in many of their sentiments, and in several respects approximated to the Reformed opinions. They did not, however, separate themselves from the Catholic church; nor did they long survive the decree of Alexander VII., by which certain propositions extracted from their writings are condemned as heretical. The Jansenists are chiefly celebrated for the contest they maintained with the Jesuists, by whom they were at last overcome, and subjected to the enmity both of Louis XIV. and the Pope. (See Leclerc, *Bibl. Univ.* vol. xiv.; Racine, *Histoire du Port Royal;* Fontaine, *Mémoires pour servir à l'Hist. du P. R.; Saint Simon's Memoirs;* Palmer, *Essays on the Church*, i. 320. &c.; *Hallam on the Literature of Europe*, vol. iii.; Schrökh, *Kirchengeschichte, seit der Reformation*, parts iv. and vii.; *Mosheim*, translation, ed. 1790, vol. v. 208. &c.)

JANTHI'NA. (Gr. *ιανθον, violet colour.*) A genus of Gastropodous Testaceous Mollusks, so denominated on account of the beautiful violet colour of the shell. There are but a few species of this genus known, all of which are marine, and are generally met with floating on the surface of the ocean in warm and tropical latitudes. The shell, as in all floating pelagic Testacea, is light and fragile, whence the specific name of the most common species (*Janthina fragilis*); but besides this relation of the shell to the habits and sphere of existence of the animal, each species also possesses a peculiar organ, by which it can, as it were, suspend itself to the surface of the water, and which has not hitherto been observed in any other molluscous species: this organ consists of a congeries of transparent vesicles filled with air, the parietes of the bubble-like cells being composed of a thin colourless condensed mucus, and the whole being attached to the posterior part of the foot. On account of this place of attachment, the vesicular float has been regarded as the analogue of the operculum, which otherwise is wanting; but there is an important difference connected with the float, viz. the power which the animal has, and frequently exercises, of detaching and reproducing it at will. Thus the mucous air-vesicles are cast off when the animal desires to sink: they are also made subservient to the reproductive economy of the janthina, which attaches its egg-cells to the under surface of the float, and when it is thus laden casts it off. By this means the ova are preserved in a situation where they may best receive the full influence of heat and light; and the power which the parent possesses of reproducing its float obviates the inconvenience which would otherwise result from this contribution to the well-being of its offspring. The following is the process by which the janthina has been observed to repair a mutilation purposely made in its float:—The foot was advanced upon the remaining vesicles until about two thirds of that part rose above the surface of the water; it was then expanded to the uttermost, and thrown back upon the water, like the foot of a Lymnea when it begins to swim; it next became contracted at the edges, and was formed into the shape of a hood, enclosing a globule of air, which was slowly applied to the extremity of the float; there was now a vibratory movement throughout the foot, and when it was again thrown back to renew the process the globule was found inclosed in its newly made envelope. From this it results that the membrane inclosing the cells is secreted by the foot, and

that there is no attachment between the float and the animal other than that arising from the nice adaptation and adjustment of the adjoining surfaces.

The genus *Janthina* belongs to the Pectinibranchiate order of Gastropods; the branchial cavity is capacious, and contains two pectinated gills. Cuvier places the genus between *Pyramidella* and *Nerita;* M. Roux considers it to be intermediate to *Ampullaria* and *Litiopa.*

JA'NUARY. The first month of the year. By some the name is derived from Janus, a Roman divinity; by others from janua, *a gate.* The months of January and February were inserted in the Roman year by Numa Pompilius. The Roman feast of the kalends of January seems to have been converted in the 6th century into the Christian festival of the circumcision. (Beugnot, *Destr. du Paganisme en Occident,* vol. ii.)

JA'NUS. A Latin deity, originally the same as the sun. He was represented with two faces looking opposite ways, and holding a key in one hand and a staff in the other. He presided over the commencement of all undertakings, whence the first month in the year was named after him. His temple at Rome was kept open in the time of war, and shut in peace. The warlike disposition of the Romans is manifest from the fact that this temple was only shut six times in 800 years: viz. once in the reign of Numa; at the conclusion of the first Punic war; thrice in the reign of Augustus; and once again under Nero.

JAPA'NNING. The art of covering paper, wood, or metal with a thick coat of a hard brilliant varnish: it originated in Japan, whence articles so prepared were first brought to Europe. The material, if of wood or papier-machée, is first sized, polished, and varnished; it is then coloured, or painted in various devices, and afterwards covered with a highly transparent varnish or lacquer, which is ultimately dried at a high temperature and carefully polished.

JA'RGOON. In Mineralogy, one of the varieties of *zircon.*

JARL. A word of Scandinavian extraction, signifying noble; applied in the early history of the northern European kingdoms to the lieutenants or governors appointed over each province. It appears to bear considerable analogy to the English earl (quod vide).

JASMINA'CEÆ. (Jasminum, one of the genera.) A small natural order of Exogenous plants, with monopetalous diandrous flowers of a regular figure. It contains few species, chiefly inhabiting the warmer parts of the world. The only plants of any interest are the jasmines, well known for their fragrance.

JA'SPER. A siliceous mineral of various colours; sometimes spotted, banded, or variegated. It takes a fine polish, and the variety and richness of its colours render it useful in the ornamental arts.

JAU'NDICE. A disease characterized by a yellow colour of the eyes and skin, deep-coloured urine, and pale evacuations from the bowels; it comes on with languor, loss of appetite, dyspeptic symptoms, vomiting, bitter taste in the mouth, and generally pain in the region of the liver. It is apparently caused either by obstruction of the duct that conveys the bile into the intestine by a gall stone; or by a morbid and viscid state of the bile, which prevents its flowing freely; or by spasm of the gall ducts, or by some accidental pressure: the consequence is that the bile, instead of passing off by the bowels, is absorbed into the blood, and becomes visible upon the skin, and especially in the more delicate vessels. It is an occasional consequence of pregnancy. It sometimes affects infants soon after birth; in which case it usually goes off in a few days, aided by gentle aperients. The most common cases of jaundice are probably occasioned by viscidity of bile. Aperients and small doses of blue pill, with tonics, are the most essential remedies; and where it ensues in sedentary habits, moderate walking and horse exercise are requisite. It is often a protracted and troublesome complaint, and then indicative of structural derangement. Jaundice from gall stones is often attended by excruciating pain and vomiting, owing to the passage of the stone. Opiates and such remedies as allay the irritability of the stomach are to be had recourse to, and the warm bath is useful. It is the beneficial influence of saline aperients and diluents in this disorder, that has given celebrity to the waters of Cheltenham and similar mineral springs.

JA'VELIN. (Fr. javeline.) A sort of spear or missile, anciently used both by horse and foot soldiers. It was about five feet long, with an iron head hooked and jagged at the end. The *pilum* of the Romans was of this description.

JAY. The native bird so called is a species of the genus *Garrulus,* separated by Cuvier from the genus *Corvus* of Linnæus on account of the weaker mandibles terminating in a sudden and nearly equal curve. The tail is cuneiform, not long; and the slender feathers of the forehead can be erected like a crest. The common jay (*Corvus glandarius,* Linn.) nidificates in woods, and builds a simple nest of sticks and slender twigs; the female lays five or six eggs, of a greyish ash-colour mixed with green, and faintly spotted with brown. The young associate with the parents till the following spring, when they separate to form new pairs.

JEERS. Strong tackles for *swaying up* or raising the lower yards.

JE'FFERSONITE. In Mineralogy, a species of *pyroxene.* It is found in New Jersey.

JEHO'VAH. The name by which the Deity is represented in the Hebrew Scriptures; in which language it signifies the *Self-existent,* the *I Am.* The word itself was held in peculiar veneration by the Jews, who never allowed themselves to pronounce it in the reading of their sacred books, but substituted for it wherever it occurred the term Adonai, or *Lord.* This practice is maintained even to this day; nor will they *write* the word in perfect Hebrew letters. And agreeably to this scruple they have left the word Jehovah imperfectly written over the beautiful altar-piece in the recently-erected synagogue in St. Helen's Place; making it to resemble that word, but in reality to signify *the Beloved.*

JEJU'NUM. (Lat. jejunus, *empty.*) The second division of the small intestines; so termed because when examined after death it is generally found empty or nearly so.

JELLY. *See* GELATIN.

JERBOA. *See* DIPUS and HELAMYS.

JE'SUATES OF SAINT JEROME. A religious order, founded in 1363 by Giovanni Colombino, of Sienna: of extremely ascetic habits in its origin. It was suppressed by Clement IX. in 1668.

JE'SUITES DE ROBE; applied to secular persons of high rank bound to the order of Jesuits by vows of obedience, without, however, having taken the spiritual vow.

JE'SUITS, or THE SOCIETY OF JESUS. The most celebrated of all the Romish religious orders; founded by Ignatius Loyola, a Spaniard, in the year 1534, when he, with Francis Xavier and four or five other students at the University of Paris, bound themselves to undertake the conversion of unbelievers. The first principle of the society which was then formed was implicit submission to the commands of the Holy See: in consideration of which their order was confirmed in 1540 by Pius III.; and from that time to the present, though with many alternations of success and reverse, the Jesuits have been one of the main bulwarks of the authority of Rome, and have exercised immense influence in the destinies of the Christian world. The zeal which they manifested at the period immediately succeeding the Reformation, when the Dominicans and other orders which had been founded on similar principles, and had faithfully executed their mission for many ages, had degenerated into luxury and indifference, secured for them the favour of the sovereigns and other political partisans of Rome. They soon became installed in the confessionals of all the Catholic kings of Europe, and throughout the 16th and following century were in fact the directors of their counsels and the rulers of their subjects.

In Protestant countries they acted as the emissaries and spies of the Pope; and in England, where early in Elizabeth's reign their landing upon our shores was made a capital crime, they persevered nevertheless in keeping alive the spirit of Roman Catholicism among the harassed remnant of the old faith; and passed and repassed the channel year after year, devoting their lives, with almost a certainty of eventually suffering, to the maintenance of an illegal, and often a treasonable, correspondence with the court of Rome and the enemies of the queen's government. At the same time another division of their numerous body employed themselves with the most undaunted energy, and with an apparent success such as has never crowned the efforts of any other missionaries, in converting the heathens of Asia and America. St. Francis Xavier, the Apostle, as he is called, of the Indies, planted Christianity in Hindostan and Japan; and Ricci introduced it into China. In the course of a few years the numbers of professing Christians in these countries became very large; although it cannot be denied both that the means which the missionaries took to increase the number of their conversions were little in accordance with the spirit of their religion, and that the form of Christianity which they allowed to be propagated was more degraded and idolatrous than that of Rome itself. It should be remarked, however, that the great secret of their success seems to have been the address with which they obtained the confidence of the ruling powers. In Japan and China they became the intimate advisers of the sovereign, and frequently obtained the assistance of the civil power in the furtherance of their missionary system.

The Jesuits obtained also, throughout Roman Catholic Europe, the direction of the education of youth: they founded many schools and colleges, not only for the instruction of those who were designed for members of their own order, but for that of the upper and lower classes generally, in the education of both of which they were eminently successful.

As a religious body, the Jesuits differ from their predecessors, inasmuch as, their principle being to conform as much as possible with the manners of the age, they have never adopted the austere observances and exclusive spiritual character upon which all earlier orders had grounded their claims to notoriety. They are divided into different classes; of which only *the professed* take the religious vows of poverty, chastity, and obedience to their superior. Among the novices are frequently enrolled influential laymen, as was Louis XIV. himself in his latter years; and this is one of the means which the order has employed to extend its efficiency where it would be least liable to observation. The Professed are of several ranks, the whole body being under the absolute control of the General, whose abode is fixed in Rome, and whose council consists of an admonitor and five assistants or councillors, who represent the five principal Catholic states, — Italy, Germany, France, Spain, and Portugal. To Rome, as the central seat of the order, are sent monthly communications from the superiors of the different provinces through which its members are distributed.

The Pope has conceded to the Jesuits greater indulgence than even to laymen, in exempting them from the religious observances which are enjoined to all Roman Catholics, and especially to the religious orders; and hence it is that they have been enabled to devote so great a portion of their time not only to instruction, but to many branches of learning and practice, by means of which they have insinuated themselves into the confidence and the concerns of the laity. They are remarkable also for the worldly air which when occasion serves they studiously assume, — for the ease with which they dispense with all the outward appearance of their spiritual character in places where their objects seem to be more attainable by a different behaviour; and they have been reproached at all times with allowing themselves on the same principle to make use of mental reservations and other *pious frauds* in pursuance of the peculiar ends of their society. Hence, even when their influence in Europe was at its height, great distrust was manifested towards them in many quarters. In France they were supposed to be implicated in the plots by which Henry III. fell, and the life of Henry IV. was attempted, and were indeed banished from that country by royal decree before the end of the 16th century: they were re-admitted, however, and continued in the enjoyment of their full influence in spite of the strong opposition of the Jansenists in the reign of Louis XIV. They were banished, in the course of the 18th century, from France, Spain, Portugal, and other Catholic states; and in 1773 Clement XIV. issued a bull by which he decreed the total abolition of the order. The invitation, however, of Catherine II. into Russia, and the favour of the successor of Clement, restored them in some degree; and they still exist and exercise considerable influence in Italy and Spain. From Russia they are at the present moment entirely banished; nor has Portugal re-admitted them since their expulsion in 1759. In France and Germany their presence appears to be connived at, though they have never formally been allowed to re-establish themselves in those countries. In England they have been allowed to found and maintain the Roman Catholic college at Stonyhurst, and their numbers in Ireland are supposed to be considerable. By the Roman Catholic Relief Bill, natural-born Jesuits resident in the United Kingdom are required to register themselves with the clerk of the peace in every county: foreigners must provide themselves with licences from a secretary of state.

The history of the order of Jesus has often been written; but with so much exaggeration both of friends and enemies, that it is difficult to point out a fair account. The *Historia Jesuitica* of Hospinian, a Protestant, carries it down to the end of the 16th century. *Orlandi and Sacchetti's History of the Jesuits* was proscribed by the parlement of Paris; a 5th part was added to it by Souvency. Coudrette, one of the order, published a history of it just before its dispersion, 6 vols. 12mo., with Supplement, 1761-4. D'Alembert published an account of the destruction of the order in France, 1765. See also *Georget's Mémoires*, Paris, 1817. The celebrated *Léttres Provinciales* of Pascal contain a powerful exposure of the errors of the casuistical theologians of the 16th and 17th centuries, of whom a large proportion were Jesuits. (See also *Mosheim*, transl. (ed. 1790), iv.154.) The voluminous French collection, entitled *Nouvelles Ecclesiastiques*, continued from the reign of Louis XIV. to the Revolution, was under the management of Jansenists, and contains every charge which hostility could suggest against the Jesuits. *Ranke's History of the Popes of the 16th and 17th Centuries* contains much valuable matter relative to that period.

JESUITS' BARK. *See* CINCHONA, or PERUVIAN BARK.

JET. A bituminous carbon. Some varieties admit of polish, and are used for ornamental purposes.

JET D'EAU. (Fr.) A fountain which throws up water to some height in the air. According to the theory of hydrostatics, the velocity with which water issues from an orifice is equal to that which would be acquired by a heavy body in falling through a height equal to the difference between the levels of the orifice and the fountain head; whence, if the resistance of the air and other impediments were removed, the height of the jet would be equal to that of the surface of the reservoir. Among the causes which prevent the jet from obtaining the height which theory assigns to it, the following are the principal: — 1st, The resistance of the air, which is proportional nearly to the square of the velocity. 2d, The friction against the sides of the pipe and the orifice through which the water issues. 3d, The velocity of the particles diminishing at every instant as they ascend, the lower particles of the ascending column press against those next above them; and the pressure being by the nature of fluids communicated in all directions, the consequence is that the column is enlarged and proportionally shortened. 4th, The water at the top of the jet does not fall off instantaneously when its velocity is destroyed; it rests for a moment at the top of the column, where its weight opposes an obstacle to the particles next succeeding, which retards their velocity, and this retardation is communicated to the whole column. This last obstacle may be avoided by slightly inclining the jet from the vertical; and it is found by experience that a jet so inclined plays higher than one quite upright, though the effect is thereby rendered less pleasing. It is necessary that the diameter of the adjutage or orifice be considerably less than that of the pipe. (See *Desagulier's Experimental Philosophy*; Mariotte, *Mouvement des Eaux.*)

JE'TERUS. A disease of plants, where the system becomes affected with a general yellowness.

JEWS' HARP. An instrument of metal, with a flexible vibratory thin metal tongue fixed to its circular base; on which tongue the breath, acting in different degrees of force, produces something like a modulated air. Shaped thus, . The outer bars are placed between the teeth, and the central piece or tongue is set in vibration by the action of the fingers.

JEW STONE. The fossil spine of a large egg-shaped echinus.

JE'ZIDS, or DA'VASIN. A sect of religionists, long settled in the mountainous country near Mosul: said to be disciples of Yezid Ben Anisa, a Mohammedan doctor. Their religion, however, is said to be a mixture of the ancient Manichean belief of those regions with the tenets of Mohammedanism and Zendism. They appear to be on better terms with the Christians than with the neighbouring Turks, by whom they are characterized as worshippers of the Devil (Arab. *Scheitan*), whose name, it is said, no threats of punishment will force them to pronounce, and whom they only mention by periphrases, as "the great sheikh," or "he whom you know of." They live in villages, huts, and tents, and are dreaded for their ferocity and robber-like habits. They are noticed at length in a preliminary dissertation to *Sylvestre de Sacy's Description du Pachalik de Bagdad*, 1809; said to be the work of Father Garzoni, who was eighteen years a missionary in Kurdistan. (See the art. "Jeziden" in *Ersch and Gruber's Encyclopædia.*)

JIB. A large triangular sail, between the fore-topmast head and the boom (thence called jib-boom), which projects beyond the bowsprit.

The effect of this sail would seem to be to lift the ship's head; yet seamen find that as the wind freshens it causes the ship, on the contrary, to plunge, and they either *ease it in* (along the boom), or haul it down. This anomalous effect may be explained as follows: —

Let x and z be the horizontal and vertical co-ordinates of the centre of effort, the centre of gravity of the vessel being the origin: let P be the resultant of the pressures on the sail. This may obviously be resolved into three: δ the direct effort along x, λ the lateral effort along y, and ϱ the vertical effort in z. The moment to raise the bow is $x\varrho - z\delta$. If $z\delta$ exceed $x\varrho$, the effect is negative, or tends to depress the bow. In all vessels $x > z$, also $\delta > \varrho$ generally; hence the effect is not so decided as it may appear at first to be.

Let ι be the angle which P makes with the horizon, and φ be the angle between x and the horizontal projection of P; then $\varrho = \text{P} \sin.\iota$, and $\delta = \text{P} \cos.\iota \cos.\varphi$: hence the effect is

$$\text{P}\,(x \sin.\iota - z \cos.\iota \cos.\varphi).$$

When the wind is aft, $\varphi = 0$, and $\iota = 90 - \varkappa$ (the inclination of the jib-stay to the horizon nearly); and the effect is

$$\text{P}\,(x \cos.\varkappa - z \sin.\varkappa),$$

which, as $\varkappa = 45^{\circ}$, is positive or lifting.

When the wind blows fresh, the vessel being close-hauled and heeling over, the stay *sags* to leeward; and the after-leech being also slacker than the foot, the resultant P may become horizontal, or $\iota = 0$, or even negative; in which last case the effect is

$$-\,\text{P}\,(x \sin.\iota + z \cos.\iota \cos.\varphi)$$

which is altogether depressing. If now the jib be eased in, x and z are diminished. Hence, in general, the plunging effect of the jib is owing to the heeling of the ship, and to the sheet being too flat aft. The like reasoning obviously applies to staysails.

JIB DOOR. (Derivation uncertain.) In Architecture, a door so constructed that it stands flush with the adjoining face of the wall on both sides, and without dressings or architraves. Thus it appears part of the wall, the intention being to conceal even the appearance of a door.

JO'GGLED JOINTS. In Architecture, the joints of stones or other masses indented in such a way that the adjacent stones fitting into the indentations, they are prevented from being pushed away from each other by any force perpendicular to the pressures by which they are thus held together.

JO'GGLE PIECE. (Perhaps from joug, *a yoke.*) In Architecture, a truss post whose shoulders and sockets receive the lower ends of the struts.

JOHN BULL, the well-known collective name of the English nation, was first used in Arbuthnot's satire, *The History of John Bull*, usually published in Swift's works; in which the French are designated as Lewis Baboon, the Dutch as Nicholas Frog, &c.

JOI'NERY. (Fr. joindre.) In Architecture, the art of framing wood-work for the finishing of houses, such as doors, sashes, shutters, &c. The term Carpentry is applied to the rough timbering, in which the only tools used are the axe, adze, chisel, and saw.

JOINT STOCK COMPANY. In Mercantile Law, a partnership consisting of a large number of members, whose rights and liabilities are defined by certain peculiar regulations imposed by themselves, generally contained in an instrument termed a deed of settlement, and heretofore in an act of parliament passed for the purpose; but now, by 4 & 5 W. 4. c. 94., the king is enabled to grant the necessary powers by letters patent. The deed constitutes trustees, directors, and other officers; contains the necessary covenants; limits the number of shares, &c.; and details the rules to be adopted in the management of of the concern. By a clause contained in this instrument the shares are rendered transferable by each partner without the consent of the other shareholders, subject, in general, to the approbation of the directors. The act of parliament, or letters patent, enables the company to sue and be sued in the name of its secretary or other officer, &c. It concludes with the customary proviso, that nothing therein contained shall be construed to incorporate the partnership.

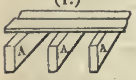
JOINT TE'NANCY, in Law, is where lands and tenements are granted to two or more persons to hold in fee-simple, fee-tail, for life, for years, or at will. It is created by particular words in a deed or devise. Its properties are said to be unity of interest, of title, of time, and of possession; and it is subject to the right of survivorship in the case of estates for life. Joint tenancy may be severed by partition, or by the alienation of any party. Personal chattels may be the subjects of a joint tenancy.

JOI'NTURE. In Law, a settlement of lands and tenements made on a woman in consideration of marriage: ordinarily an estate for life. A jointure was made a bar of dower, if granted with certain requisites, by 27 H. 8. c. 10. *See* MARRIAGE, LAW OF.

JOISTS. (Fr. joindre.) In Architecture, the timbers of a floor whereto the boards or laths for the ceiling are nailed. They either rest on the walls or on girders, or sometimes on both.

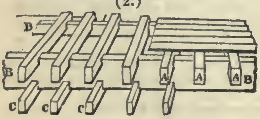
Where only one tier of joists is used, it is called *single flooring* (fig. 1.), A A A being the joists; and in this sort of flooring such joists should not exceed sixteen feet in length or bearing, and even when the length is more than eight feet they should have stiffening pieces to prevent torsion.

(1.)



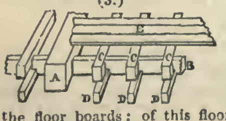
When two sets of joists are used, it is called *double flooring* (fig. 2.); in which A A are called *floor* or *bridging joists*, B B the *binders*, C C C the *ceiling* joists.

(2.)



If the binding joists be framed into girders, the floor is then properly called a *double-framed floor*, of which the subjoined is a diagram (fig. 3.); wherein A is a girder, B a binding joist, C C C are bridging joists, and D D D are ceiling joists, E being the floor boards: of this floor it is manifest that the girders are the main support.

(3.)



JO'LLY-BOAT. *See* YAWL.

JOU'RNAL. (Ital. giornale, *i. e.* diurnale.) Strictly a record or account of daily occurrences. It is more extensively employed to signify a narrative, periodically or occasionally published, of the transactions of a society, &c.; as by ourselves in the phrase "Journals of the Houses of Parliament," &c. It is also used as synonymous with *Magazine*, or other periodical publications of that class.

JU'BA. (Lat. *a mane.*) The long and thick-set hairs which adorn the neck, chest, or spine of certain quadrupeds.

JUBILA'TE. (Lat. *rejoice.*) A name given to the third Sunday after Easter; so called because in the primitive church divine service was commenced with the words of the 66th Psalm, "Jubilate Deo, omnes terræ," — "Sing to the Lord, all ye lands."

JU'BILEE. (Lat. jubilo, *I rejoice.*) The name given among the Jews to the grand sabbatical year, which was celebrated after every seven septennaries of years: whether every forty-ninth or fiftieth year is still a question among the learned. The institution of this festival is recorded in Lev. xxv. 8—17. This was a year of general release not only of all debts, like the common sabbatical year, but of all slaves, and of lands and possessions which had been alienated from their original owners. It has been commonly supposed that the jubilee was intended to be typical of the release and redemption of mankind under the Gospel dispensation; and it was with this idea that Pope Boniface VIII., at the end of the thirteenth century, proclaimed a general indulgence to all Christians who should visit the tombs of the Apostles at Rome in the secular year 1300. At this period it was intended that the same celebration should take place only every hundredth year. In consequence, however, of the enormous afflux of pilgrims which this proclamation brought together, and the gain which resulted from it, Clement VI. abridged the interval to fifty years; and the solemnity then received the name of the jubilee in imitation of the Jewish custom. The second jubilee was accordingly solemnized in 1350. In 1389, Urban V. reduced the term to thirty-three years, the number of the life of our Saviour: it was raised again by Nicholas V. to fifty; and finally, in 1470, fixed by Paul II. at twenty-five; and the jubilee has ever since been solemnized every quarter of a century, beginning on Christmas eve, when the Pope opens with great pomp the door of St. Peter's, closed except on that occasion. (*Mosheim's Eccl. Hist.*, Transl., ed. 1790, iii. 263.)

JU'DAISM. Attachments to the rites of the Jewish law. The Judaizing spirit of many of the early Christians is a subject of observation in many of St. Paul's Epistles (especially that to the Galatians), and continued for a long period to exercise much influence on the character of the religion. (See *Milman's Hist. of Christianity*, vol. i. 21. 451. &c.)

JU'DGES. (Lat. judex.) Certain supreme magistrates who presided over the Israelites from the time of Joshua to the reign of Saul, a period of about 330 years. They were so called because they formed at once the civil and the military governors of the people. The dignity was retained for life, though it was not always hereditary.

JU'DGMENT. (Lat. judicium.) In Law, the sentence of the law pronounced by the court upon the matter contained in the record. The term judgment, in English legal language, is restricted to the decisions of a court of common law: those of a court of equity are denominated decrees. Judgments are said to be of four sorts:—1. Judgments in law (on demurrer, where the facts are confessed upon the pleadings); 2. Judgments in fact (on the verdict of a jury); 3. Judgments by confession or default, *i. e.* where both facts and law are admitted by the defendant; 4. Judgments on a nonsuit or retraxit, where both fact and law are admitted by the plaintiff, who thereupon withdraws his claim. Judgments are also said to be either interlocutory, on matter arising in the course of the proceeding; or final, on the merits of the case. Judgments, when obtained, must be signed by the proper officer, and entered of record, without which they are not judgments. Arrest of judgment arises from error appearing upon the face of the record; but such error must now be, generally speaking, in substantial matter of law, and not on mere matter of form.

JU'DGMENT, in Logic, is defined to be the second of the three logical operations of the mind. It is the comparing together two of the notions which are the subjects of simple apprehension, and pronouncing that they agree or disagree with each other. Judgment, therefore, is either affirmative or negative; and the subjects of judgment are *propositions*, which are expressions of the agreement or disagreement of one term with another.

JU'DGMENT. In the Fine Arts, the faculty of selecting that which is most suitable to the purpose.

JU'DICA. (Lat. *judge.*) The fifth Sunday after Lent was so called, because the primitive church began the service on that day with the words of the 43d Psalm, "Judica me, Domine,"—"Judge me, O Lord."

JUDI'CIUM DEI. (Lat. *judgment of God.*) The

term formerly applied to all extraordinary trials of secret crimes, as those by arms, single combat, ordeals, &c.; in which it was believed that Heaven would miraculously interfere to clear the innocent and confound the guilty. (*See* ORDEAL, QUESTION.) Full particulars of the ceremonies instituted on such occasions will be found in *Ducange*.

JU'GAL BONE. (Lat. jugum. or Gr. ζυγον, *a yoke.*) The cheek bone; so called because it has a *yoke-like* articulation to the bone of the upper jaw.

JUGA'TA. Two heads represented upon a medal side by side, or joining each other.

JU'GGERNAUT. *See* VISHNU.

JU'GGLERS. (Fr jongleurs.) A general denomination for those persons who practise the arts of legerdemain, or who exhibit feats of uncommon strength or dexterity. The reader will find in *Beckman's History of Inventions* a learned and curious account of the origin and history of all the feats of this kind exhibited both in ancient and modern times.

JUGLANDA'CEÆ. (Juglans, one of the genera.) A small natural order of Exogenous trees, distributed through the temperate parts of North America and Asia. The common walnut, *Juglans regia*, is well known for its agreeable fruit, and the useful oil it yields by pressure. Hickory, a very elastic kind of timber, is the wood of *Carya alba;* and that of other species, especially *Juglans nigra* and *regia*, is valuable for cabinetmakers' work and similar purposes.

JU'GULARS, *Jugulares.* (Lat.) The name under which Linnæus comprehended all those fishes which have the ventral fins anterior to the pectorals.

JU'GULAR VEINS. (Lat. jugulum, *the throat.*) The veins which bring the blood from the head, descending upon the sides of the neck: they are divided into *external* and *internal*. By their union with the subclavian vein they form the superior *vena cava*, which terminates in the superior part of the right auricle of the heart.

JU'GULUM. (Lat. *the throat.*) In Mammalogy, it is restricted to the fore-part of the neck, which intervenes between the throat (gula) and the chest. The *fossa jugularis* is the hollow in front of the sternum at the base of the neck.

JUJU'BE. The fruit of the *Rhamnus zizyphus:* it resembles a small plum, and is occasionally used as a sweetmeat. What is sold under the name of *jujube paste* professes to be the dried jelly of this fruit, but is in fact a mixture of gum arabic and sugar slightly coloured.

JU'LIAN ÆRA. The commencement of a period invented to correspond with the cycles of the Julian year. It coincides with the 710th year before the creation of the world, according to common chronology.

JULIAN CALENDAR. The civil calendar introduced at Rome by Julius Cæsar, and used by all the Christian countries of Europe till it was reformed by Pope Gregory XIII. in 1582. Before the time of Julius Cæsar the Roman year was lunisolar; and as the pontiffs, who had a discretionary power of adjusting the calendar, followed no certain rule in their intercalations, but sometimes inserted a greater or less number of days for the purpose of prolonging or shortening the period of a particular magistracy, the civil year did not long correspond with the astronomical or the course of the seasons, and the reckoning of time fell into great confusion. With the advice of the astronomer Sosigenes, Cæsar fixed the mean length of the year at 365¼ days; and in order that the year should always commence with the commencement of a day, he decreed that three successive years should contain 365 days, and the fourth 366, and so on for ever. He also restored the vernal equinox to the 25th of March, the place it occupied in the time of Numa; and thus fixed the correspondence of the civil year with the seasons.

In distributing the days of the year among the twelve calendar months, Cæsar adopted a very commodious arrangement, which unfortunately was not long suffered to prevail. He ordained that the odd months, viz. the first, third, fifth, seventh, ninth, and eleventh, should have each 31 days, and the even months 30 days; with the exception of February, which in common years should have only 29, but in the intercalary years 30 days. This was as simple and natural a disposition as, perhaps, it is possible to make; but the whole arrangement was soon thrown into disorder and confusion, to gratify the frivolous vanity of Augustus, by giving to the month which he had named after himself the same number of days as July, which bore the name of the first Cæsar. A day was accordingly taken from February and given to August; and in order that three months of 30 days might not come together, September and November were reduced to 30 days, and 31 given to October and December. Such was the origin of the capricious arrangement which has ever since been adhered to. *See* CALENDAR.

JULIAN EPOCH. In Chronology, the epoch or commencement of the Julian Calendar. The first Julian year commenced with the 1st of January of the 46th year before the birth of Christ, and the 708th from the foundation of Rome.

JULIAN PERIOD, in Chronology, is a period consisting of 7980 Julian years. The number 7980 is formed by the continual multiplication of the three numbers 28, 19, and 15; that is, of the cycle of the sun, the cycle of the moon, and the cycle of indiction. The first year of the Christian era had 10 for its number in the cycle of the sun, 2 in the cycle of the moon, and 4 in the indiction. Now the only number less than 7980 which, on being divided successively by 28, 19, and 15, leaves the respective remainders 10, 2, and 4, is 4714. Hence the first year of the Christian era corresponded with the year 4714 of the Julian period; and hence also the year of our era corresponding to any other year of the period, or *vice versâ*, is found by the following rule:—

1. When the given year is anterior to the commencement of the era, subtract the number of the year of the Julian period from 4714, and the remainder is the year before Christ; or subtract the year before Christ from 4714, and the remainder is the corresponding year in the Julian period.

2. When the given year is after Christ, subtract 4713 from the year of the period, and the remainder is the year of the era; or add 4713 to the year in the era, and the sum is the corresponding year of the Julian period. (*Ency. Brit.*, art. "Chronology.")

JU'LIAN YEAR. The year adopted in the calendar of Julius Cæsar, and equal to 365¼ days. The Julian year exceeds the mean solar year, as determined by the best astronomical observations, by 11 minutes and 10·35 seconds, which amounts to a day in 129 years. In the course of a few centuries this error would become very perceptible, as the equinoxes and solstices would fall back towards the beginning of the year. When the Julian calendar was introduced by Cæsar the vernal equinox fell on the 25th of March; at the time of the Council of Nice, in 325, it fell on the 21st; and at the reformation of the calendar, in 1582, it had retrograded to the 11th. This observation enabled Pope Gregory to fix the length of the year more precisely, and correct the intercalations. *See* CALENDAR.

JU'LIS. (Lat. *the name of a fish.*) A genus of Labroid fishes, distinguished by the following characters. — Head smooth; cheeks and gill-covers without scales; lateral line bent suddenly downwards when opposite the end of the dorsal fin. The rainbow wrasse (*Julis Mediterranea*) has been taken on the coast of Cornwall.

JULY, so named by Mark Antony, in honour of Caius Cæsar, the dictator, whose gentile name was Julius, is at present the seventh month of the year. In the Latin calendar it was the fifth, and hence was termed *Quintilis.* The Dog-days are supposed to commence on the 3d of this month.

JU'MPING HARE. A Rodent quadruped, the largest of the family of the Jerboas (*Dipodidæ*), and the type of the genus *Helamys*, is so called. It is a native of the Cape of Good Hope, and inhabits deep burrows. *See* HELAMYS.

JUNCA'CEÆ. (Juncus, one of the genera.) A small obscure natural order of Endogenous plants, in most respects resembling *Liliaceæ*, and differing chiefly in their flowers being glumaceous; that is, thin, dry, and either brown or green in colour. There are, however, species intermediate between the two orders in this respect. None of the species are of any importance. The common rush is the usual type of this order.

JUNCA'GINACEÆ. A small natural order of Endogenous plants growing in marshes, with minute green flowers. They are considered by botanists allied to *Araceæ*, on account of the structure of the embryo; in their general aspect they are something like little rushes.

JUNE; so named, according to some, either from the Latin Junius, Juno, or Juniores (May, as was alleged, being derived from Majores). At present the sixth month of the year, but in the old Latin calendar the fourth. It consisted originally of twenty-six days, to which Romulus is said to have added four. Numa afterwards deprived it of one day; which, however, was again restored by Julius Cæsar, and it has ever since remained unaltered.

JUNGERMANNIA'CEÆ. (Jungermannia, one of the genera.) A very small natural order of Acrogenous or Cryptogamic plants, resembling mosses in appearance, and, like them, growing upon the bark of trees and in damp ground in shady places. They bear their seeds in cases containing spiral threads, which, by their elasticity, disperse the former when ripe. Until lately they were considered to form a part of *Hepaticæ*.

JU'NIPER BERRIES. The fruit of the *Juniperus communis*. They are used in medicine as a diuretic; but their principal consumption is in flavouring gin. When distilled with water they yield an essential oil, upon which their peculiar flavour depends. The resin of this tree is called juniper gum or sandarach, and is occasionally used in varnishes. When powdered it is

used under the name of *pounce*, to prevent ink sinking into paper from which writing has been erased.

JUNK. A large flat-bottomed vessel, with three masts, and a short bowsprit placed on the starboard bow, used by the Chinese. The masts are supported by two or three shrouds, which at times are all carried on the windward side; and the fore or main mast carries a sort of lug sail of cane of bamboo.

JU'NO. The Latin name of the divinity called by the Greeks Hera (Ἥρη). She was the sister and consort of Jupiter, and was held to preside over marriage, and protect married women. She was represented as the model of majestic beauty, in royal attire, and attended by her favourite bird the peacock. Her principal temples in Greece were at Samos and Argos. She was also the patroness of Veii, whence she was invited to Rome on the occasion of the last siege of the former city.

JU'NO. One of the four small extra-zodiacal planets which circulate between the orbits of Mars and Jupiter. Juno was discovered by Professor Harding of Lilienthal (near Bremen), on the 22d of September, 1804; Ceres and Pallas having been discovered previously. Juno appears like a star of the eighth or ninth magnitude, and is of a whitish colour, without nebulosity. This planet is distinguished by the great eccentricity of its orbit, exceeding that of any other planet, and amounting to ·2578, the semi-axis major being taken as unit. The effect of this eccentricity on the motion of the planet is such, that the half of the orbit which is bisected by the perihelion is described in about half the time in which the other half is described. The sidereal revolution is performed in 1592·66 mean solar days. The inclination of the orbit to the ecliptic is 13° 4′ 10″; and the greatest equation of the centre 29° 46′ 19″. The extreme smallness of the planet renders it impossible to determine its apparent diameter, and consequently its magnitude, with any degree of certainty.

JU'NTA. (Span. *an assembly*.) A grand Spanish council of state. Besides the assembly of the states or *cortes*, there were two juntas: one which presided over the commerce, the mint, and the mines; and the other forming a board for regulating the tobacco monopoly. The assembling of a junta by Napoleon in 1808, and the part they subsequently played in Spanish history, are sufficiently known to the reader. In England the term *junto* (evidently of Spanish origin) is used almost synonymously with cabal or faction.

JU'PITER. In Mythology, the Latin name of the deity called by the Greeks Zeus (Ζεύς): it is derived from that word with the addition Pater, *Father*. He was the son of Saturn, whom he deposed from his throne, and thence became the supreme monarch of gods and men. He married his sister Juno, by whom he had Vulcan; but besides this deity he had a large progeny of gods and demigods by his numerous divine and mortal paramours. The most celebrated of his children were, Minerva, who had no mother, but sprung armed from her father's forehead; Bacchus, the Muses, Venus, Apollo and Diana, Mercury, Proserpine, Hercules, Perseus, and Minos. The most celebrated Grecian temple of this god was at Olympia in Elis, where every fourth year the Olympian games were celebrated in his honour: his most revered oracle was among the oak woods of Dodona in Epirus. The Romans considered Jupiter as especially the patron of their city, in which he accordingly had some splendid temples: that in the capitol was the grandest. Of that dedicated to Jupiter Stator there are still three columns standing. Jupiter was represented as the model of dignity; grave, but mild: he is seated on a throne grasping his sceptre and a thunderbolt, and by his side stands his peculiar bird, the eagle.

It has been remarked that there is a striking similarity between *Jove* (from *Jovis*, gen. of Jupiter), and the Hebrew name of the Supreme Deity, Jehovah.

JUPITER. In Astronomy, one of the planets, and the largest in the system. The mean diameter of Jupiter is no less than 87,000 miles, or about eleven times that of the earth; consequently his bulk is about 1300 times greater than that of the earth. The distance of Jupiter from the sun is nearly 490 millions of miles, or about 5¼ times the radius of the earth's orbit; and he performs his revolution in respect of the stars in 4332 days, 14 h. 2 m. 8½ sec., which is nearly 12 years. The inclination of the orbit to the plane of the ecliptic was 1° 18′ 51″ at the beginning of the present century, and undergoes a diminution of about a fourth of a second in a year.

"The disc of Jupiter is always observed to be crossed in one certain direction by dark bands or belts. These belts are, however, by no means alike at all times; they vary in breadth and in situation on the disc (though never in their general direction). They have even been seen broken up, and distributed over the whole face of the planet; but this phenomenon is extremely rare. Branches running out from them, and subdivisions, as well as evident dark spots, like strings of clouds, are by no means uncommon; and from these, attentively watched, it is concluded that the planet revolves in the surprisingly short period of 9 h. 55 m. 50 sec. (sid. time) on an axis perpendicular to the direction of the belts.

"The parallelism of the belts to the equator of Jupiter, their occasional variations, and the appearances of spots seen upon them, render it extremely probable that they subsist in the atmosphere of the planet, forming tracts of comparatively clear sky, determined by currents analogous to our trade winds, but of a much more steady and decided character, as might indeed be expected from the immense velocity of its rotation. That it is the comparatively darker body of the planet which appears in the belts is evident from this — that they do not come up in all their strength to the edge of the disc, but fade gradually away before they reach it." (*Herschel's Astronomy*, *Cabinet Cyclopædia*, p. 281.)

The radius of Jupiter being 11 times greater than that of the earth, and the rotation on the axis being 2·4 times more rapid, the space passed over by a point on the equator of the planet will be 26 times greater than that described by a point of the terrestrial equator in the same time. Hence the centrifugal force is about 26 times greater, and we may therefore conclude that its effect in impressing a flattened form on the planet will be much greater than takes place with regard to the earth. Now observation shows this to be the case. The disc of Jupiter is evidently not circular, but elliptic, being considerably flattened in the direction of its axis of rotation; and this appearance is no optical illusion, but is authenticated by micrometrical measures, which assign 15 to 14 as the proportion of the equatorial and polar diameters. This far exceeds the compression of the earth, the ratio of the equatorial to the polar diameter of which is 302 to 301.

The annual parallax of Jupiter is less than 12°; consequently the earth, as seen from Jupiter, will never appear at a greater distance than 12° from the sun. The digressions of Mars will be 17°, those of Venus 8°, and those of Mercury only 4° 16′. An inhabitant of Jupiter would therefore probably be ignorant of the existence of Mercury, which will be almost constantly plunged in the sun's rays, and likewise diminished in splendour, on account of the greater distance.

The density of Jupiter is very nearly the same as that of the sun, and about one fourth of the mean density of the earth. The mass of the planet, compared with that of the sun taken as unity, is ·000943; but this is sufficient to produce a very sensible perturbation of the motions of some of the other planets. The proportion of light and heat received by Jupiter from the sun, compared with that received by the earth, is as ·037 to 1.

Jupiter, through the telescope, is observed to be accompanied by four moons or satellites, which revolve about the planet nearly in the plane of its equator, exactly in the same manner as the moon revolves about the earth. Their configuration changes at every instant; they appear to oscillate on each side of the planet, and their rank or order of distance is determined by the extent of their oscillations. In coming between the sun and Jupiter, the satellites throw their shadows on the planet, and produce eclipses of the sun; and when they come to the side of the planet opposite to the sun they are eclipsed in passing through the shadow. The beginnings and endings of these eclipses can be observed with great precision; and their observation furnishes the surest means of determining the sidereal and synodic revolutions of the satellites. The same observations also afford a means of determining terrestrial longitudes; and it was by means of them that astronomers discovered and measured the velocity of light. *See* PLANET and SATELLITE.

JU'RISCONSU'LT. (Juris consultus, *learned or skilled in law*.) A title given to a class of Roman lawyers, and commonly denoted by the abbreviation *ictus*. From what we know of the jurisconsults, they appear to have been a different class from the advocati or causidici who conducted causes, and to have confined themselves to the employment of giving responsa or opinions on cases put to them. (See *Mem. de l'Ac. des Inscr.* vol. xli.) From the recorded opinions of the most learned jurisconsults the *Digest*, the great work of Justinian, was chiefly compiled. *See* ADVOCATE.

JU'RISPRU'DENCE. The science of right. (From the Latin words juris prudens, *skilled in law*.) The term *civil jurisprudence* is sometimes restricted to the science of the Roman or civil law. For a literally complete list of works on this extensive subject, see *Krug's Philosophisches Lexicon*, art. "Rechtslehre."

JURY-MAST. In Naval affairs, a temporary mast erected in a ship in the room of one that has been carried away by tempest or any other accident. Jury-masts are sometimes erected in a new ship to navigate her down a river, or to a neighbouring port, where her proper masts are prepared for her.

JURY, TRIAL BY. Of the origin and progress of this institution, as far as it has been very imperfectly traced by antiquarians, some account has been given in

the historical review of the Common Law. When issue has been taken in fact in a civil suit (*see* PLEADING), the cause stands ready for trial *at bar* of the court itself (*see* LAW, SUPERIOR COURTS), unless by the fiction of *nisi prius* (ib.) it is transferred to the sittings in London and Middlesex, or the assizes in the country. (A trial at bar is now only granted on application in some special cases.) The sheriff of the county is directed by writ of venire facias to summon jurors to attend at the assizes; and by a further compulsory process, called a *distringas*, he is ordered to distrain them by their lands and goods if they make default in appearance. On motion of either the plaintiff or defendant, the court orders a *special jury* to be summoned. The list of persons liable to serve as common jurors is made out by the churchwardens and overseers in each parish, and, after being considered by justices at petty sessions, is copied into a book and delivered to the sheriff. On the return of the writs of venire facias, the sheriff annexes a *panel* or list of persons taken from this book, in number from 48 to 72; and the judges are empowered to direct the same panel to attend both for the civil and the criminal sides, amounting in all to 144. The twelve jurors who are to try the cause are chosen by ballot out of this list. The qualification of a common juror is, to be a natural-born subject (unless on trial of an alien, in which he may if he pleases have a jury *de medictate linguæ*, of which one half consists of aliens), to be free from attaint of an infamous crime, and to be between the ages of 21 and 60. All such persons (with certain privileged exceptions) possessing 10*l*. a year in freehold or copyhold lands and tenements, or 20*l*. a year in lands held on lease for 21 years, or rated as householders to the poor's rate in Middlesex for 30*l*., elsewhere 20*l*., or occupying a house with 15 windows, are liable to serve. In the city of London the juror must be a householder or occupier within the city, and have property, real or personal, to the amount of 100*l*. All persons described in the jurors' book as esquires or of a higher degree, or as bankers or merchants, are qualified to serve on special juries. If on a trial sufficient qualified jurors are not in attendance, a *tales* may be prayed; and bystanders are called in to fill up the number. This seldom occurs but in special jury cases; and in these the *talesmen*, as they are vulgarly termed, are taken from the common jury list.

The jury being summoned, the trial proceeds; unless either party *challenge* the jurors. *Challenges* are either *to the array* or *to the polls*. A challenge to the array is an objection to the whole panel, and can only be on account of default or partiality of the sheriff. Challenges to the polls, *i. e.* to individual jurors, are said to be of four kinds; *propter honoris respectum*, *propter defectum*, *propter affectum*, and *propter delictum*. 1. Where a party is exempted by statute from serving, he may challenge himself. 2. Insufficient qualification is a ground of challenge by either party. 3. On supposed bias or partiality, as by reason of kindred. Challenges to the favour are on a mere suspicion of partiality. 4. Legal infamy is the fourth ground of challenge. In a criminal case the law of challenges is the same as in a civil one; except that the prisoner for felony has the additional privilege of making *peremptory* challenges without cause assigned to any number of jurors not exceeding twenty. Challenges for cause, if *to the polls*, are tried by the court; except those to the favour, which the court appoints two jurors if sworn, if not two indifferent persons, to try. Challenges to the array are tried entirely at the discretion of the court.

According to the common course of a trial at nisi prius, the counsel for that party on which the affirmative of the issue is thrown by the pleadings (that is, except in occasional cases, the plaintiff) *opens his case* by a statement to the jury, and then calls witnesses to prove it. The counsel for the other party then replies; and if he also calls witnesses, the first speaker has a final reply. After the evidence is given and the case closed, the jurors are kept together to deliberate of their verdict. They must be without meat, drink, or fire, unless otherwise ordered by the judge; and as unanimity is necessary to a verdict, it was held at common law that if the jury could not agree, the judge might cause them to be carried round the circuit from town to town in a cart. In practice it is usual, when they cannot be brought to agreement, to discharge the jury. Although the jury in ordinary language are said to be judges of the *fact* only, yet a general verdict in a civil or criminal case ordinarily decides both the facts, and whether the law as stated by the judge is immediately applicable to those facts: *e. g.* a verdict "guilty" on a charge of murder implies both that the act was committed, and that it was committed under circumstances amounting to murder. The jury may, however, find under certain circumstances a *special* verdict, that is, a verdict in which the facts of the case are specially stated, and it is left to the court to apply the law; or they may find a general verdict, subject to a special case as to a point of law. In cases of criminal prosecution for libel, much difference of opinion formerly prevailed as to the effect of a verdict. It was held by most lawyers that the only questions for their consideration were the fact of publication, and the truth of what is technically called *the innuendos*, viz. that the passages of the libel cited did apply to such or such facts and individuals. But by 32 G. 3. c. 60. (passed through the influence of Mr. Fox) it was enacted that on every trial of an indictment or information for libel the jury may find a general verdict of guilty or not guilty upon the whole matter in issue, thus deciding whether the matter published amounts to a libel or no. As to the grand jury, see LAW, CRIMINAL.

JUST, or **JOUST**. (Ital. giostra.) A combat between two persons with lances: properly, a mere amicable contest or trial of strength. *See* TOURNAMENT.

JUSTE MILIEU. *See* MILIEU JUSTE.

JUSTICES OF THE PEACE, in Law, are descended from the ancient conservators of the peace, and are appointed to their office in every county by the king's special commission under the great seal; which appoints them all, jointly and separately, to keep the peace, and any two or more of them to inquire of or determine felonies and misdemeanours. Some justices, also, are so by act of parliament (namely, a few high ecclesiastical officers); and some by charter or grant, as the mayor and other magistrates in corporate towns. Some justices are expressly nominated in the commission, so that certain business cannot be transacted without their presence; these are said to be of the *quorum*, and all the justices are now usually included in the list. The qualification of a justice is to have an estate of 100*l*. a year free of incumbrance, or a reversion after one or more lives of 300*l*. a year; but many privileged persons may act without qualification by estate. A justice intending to act under this commission sues out a writ of *dedimus potestatem* from the clerk of the crown in chancery, and takes certain usual oaths.

The duties and powers of a justice of the peace are of two kinds; ministerial and judicial. 1. He acts in the former capacity in preserving the peace; hearing charges against offenders; examining the informant and his witnesses; binding over the parties to prosecute or give evidence; and committing, or admitting to bail, according to the nature of the offence, parties who are brought before him. The stat. 7 & 8 Geo. 4. c. 64. requires justices to take the most material part of the evidence on examinations before them in writing, to be returned to the assizes, both in charges of felony and misdemeanor. 2. An extensive jurisdiction, summary and formal, is now exercised by justices of the peace, numerous branches of judicature, both criminal and civil, having been gradually confided to their authority, either exercised by them individually, or at the petty sessions and general quarter sessions of the peace. The latter court, by 34 Ed. 3., has jurisdiction over all felonies and trespasses whatever: in practice, simple larcenies and many other felonies and small misdemeanors are tried by a jury before it. It has also by various statutes jurisdiction over several offences relating to highways and to game; it is an appellate court from many decisions of individual magistrates; and it has one large and exclusive power committed to its care by the legislature, viz. the hearing and deciding appeals from orders of magistrates relative to the imposition of the poor's rate, and to the removal of paupers from one parish to another in which they are shown to have a legal settlement. (*See* SETTLEMENT.) Justices have, either singly or jointly, summary jurisdiction in questions of contract between certain classes of masters and servants; in small illegal takings of property, whether strictly personal, or in part connected with the freehold, not exceeding 5*l*. in value; and in common assaults and batteries not causing injury exceeding 5*l*. (in the latter case two justices are required); and in certain malicious injuries to property. The proceedings are in general on a written charge, sometimes termed a complaint; but in proceedings for a penalty more generally an information: on receiving which, the justice grants a summons to cause the appearance of the party charged. An appeal to the quarter sessions from the conviction or order of justices is sustainable only where expressly given by statute; and the court of session, on hearing the case, is said either to *affirm* or *quash* the conviction or order. And the proceedings are further removable in some cases into the superior courts by certiorari.

Other summary remedies afforded by magistrates are in cases of forcible entry and detainer, and some that arise between landlord and tenant.

Justices of the peace are liable to actions at the suit of parties injured by them wilfully in the exercise of their authority. But it is provided by statute that they shall have notice of any action commenced against them, and the cause of such action, one month before the writ is sued out; and the action must be commenced within six months after the injury complained of. Persons recovering a verdict against a justice for any wilful or malicious injury are entitled to double costs. These magistrates are also punishable criminally by indictment or information.

The police justices of London and its vicinity are stipendiary magistrates, created by act of parliament.

JUSTI'CIARY, CHIEF. (Lat. magnus justiciarius, or capitalis justiciarius totius Angliæ.) An officer of high power and dignity under the Norman kings of England, who presided over all functionaries in the aula regia, or king's court, so long as it followed the person of the king; and was, says Blackstone, by virtue of his office, guardian of the realm in the king's absence. The formidable power of the chief justiciary was curbed to some extent by the provisions of the great charter, especially that which fixed the trial of common pleas at Westminster; and became altogether obsolete when the various branches of his jurisdiction were broken into distinct courts of judicature under Edward I. (*Bl. Com.* iii. 39.)

JUSTI'CIARY, THE HIGH COURT OF, IN SCOTLAND, is composed of five of the Lords of Session, added to the Justice-Clerk, the president of the court. It is the supreme court of criminal justice; with the power of advocating or suspending all sentences of inferior criminal judges. It has circuit courts twice a year; and an additional circuit is now held in Glasgow during the Christmas recess of the Court of Session. The sinecure office of Lord Justice-General was in 1831 merged in that of the Lord-President. *See* SESSION, COURT OF.

JUSTI'CIES. In Law, a special writ empowering the sheriff of a county to hold plea of an action in his court. By means of this writ all personal and many real actions may be tried in the county courts.

JUSTIFICA'TION. (Lat. transl. of the Greek word δικαιωσις.) In Theology, men are said to be justified when accounted just or righteous in the sight of God, or placed in a state of salvation. Justification is used of the state of Christians in the present life only; as in Rom. v. 9., "Being justified by his blood, we *shall be* saved from wrath through him." The doctrine of justification through faith or rather by faith (εκ πιστεως, δια πιστιν *for or by reason of faith*) is set out with peculiar distinctness in the whole Epistle to the Romans. According to the eleventh article of the Church of England, we are justified "by faith, and not for our works or deservings." The twelfth declares, that "although good works, which are the fruits of faith, and follow after justification, cannot put away our sins and endure the severity of God's judgment, yet are they pleasing and acceptable to God in Christ, and spring necessarily out of a true and lively faith, insomuch that by them a lively faith may be as evidently known as a tree is discerned by the fruit." The first of these articles is chiefly directed against the Romanist doctrine of meritorious works; the second, based on the language of St. James, that a "man is justified by works, and not by faith only" (c. 2. v. 24.), regards faith and works as inseparably connected, and is aimed principally against the doctrine of those who were termed Antinomians or Solifidians. For a summary of the opinions generally embraced by the best divines of the early Church of England on this difficult subject, see *Hoskin's Sermon on Justification;* for the views of what is called the High Church body of the present day, *Newman's Lectures on Justification.*

K.

K, a consonant, used in most ancient and modern languages. It is derived from the Greek *kappa*, or the Hebrew *koph*. It has the same sound as C before *a*, *o*, and *u*, and hence it has often been pronounced superfluous. In Latin K occurs only in a few words, though it was frequently used in the same language as an abbreviation for words beginning with C; as K.T. for capite tonsus, K. R. C. for cara civitas, &c. &c. In the French alphabet K is only used in words derived from foreign languages. As a numeral it was employed to express 250,—

K quoque ducentos et quinquaginta docebit.

KA'ABA. *See* CAABA.

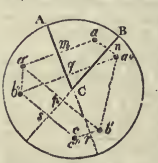
KA'KOXENE. (Gr. κακος, *bad*, and οξυς, *sharp;* so called probably from the mischief it does to the iron.) A mineral occurring in brown or red radiated crystals in the ironstone of Zbiron in Bohemia: when heated it emits a green phosphoric light. It contains phosphoric and fluoric acids, peroxide of iron, and silica.

KA'LAND. (Germ.) A lay fraternity instituted in Germany in the 13th century for the purpose of doing honour to deceased relatives and friends. The term is probably derived from kalendæ, *the first day of any month*, as the members of this society chose that day for the observance of their ceremonies. These consisted originally of prayers, followed by a slight repast, in which all the members participated; but in process of time the religious purposes of the society became wholly merged in the festivities, so that it eventually was found necessary to abolish the fraternity on account of its excesses.

KALEI'DOSCOPE. (Gr. καλος, *pretty;* ειδος, *form;* and σκοπεω, *I view.*) An optical toy invented or revived by Sir David Brewster, which, by a particular arrangement of reflecting surfaces, presents to the eye a series of symmetrical images often remarkable for their beauty. The kaleidoscope is formed by two plane mirrors or slips of glass, from six to ten inches in length, and from an inch to an inch and a half in breadth at the one end, though somewhat narrower at the other, joined together along the edges lengthwise, and inclined to each other in an angle, which must be an even aliquot part (that is to say, the sixth, eighth, tenth, &c.) of four right angles. The edges of the mirrors are kept in contact by a strip of black silk glued along the back of the plates, which, if formed of glass, must be coated with black varnish or sealing wax, to prevent reflexion from their posterior surfaces. The mirrors being adjusted at the proper angle, are placed within a tin tube, where they are kept in their proper position by pieces of cork or wood wedged in between them and the tube. One end of the tube has a small circular aperture in its centre, to which the eye is applied; in the other end two plane glasses are fixed parallel to each other, and perpendicular to the axis of the tube, and about an eighth of an inch apart. Between these glasses, which form a cell, the objects which produce the images are placed. Those which answer the purpose best are small fragments of coloured glass, beads, or other coloured diaphanous matters, of such a size that when the tube is turned round they move freely within the cell and assume new positions. In order that the eye may not be disturbed by objects without the tube, the outer glass should be slightly ground, but the inner must be perfectly transparent.

On applying the eye to the aperture of the tube the objects within the cell at the other end are seen multiplied by repeated reflexions from the two mirrors, and a succession of symmetrical images presented, all arranged round a centre, and combined into a perfect whole. As the objects are placed loosely in the cell, every motion of the tube changes their relative positions, whereby an entirely new image is produced; and it is this constant change and endless variety of new combinations which create the pleasing effect.

In order to show how this multiplication of the images is produced, let A C represent one of the mirrors, and B C the other, and suppose them to make with each other an angle of 60°: let *a* also be an object placed between the planes of the two mirrors, or one of the diaphanous bodies in the cell between the two parallel glasses at the end of the tube. Now when an object is seen reflected from a mirror, the image always appears as far behind the mirror (in a perpendicular line) as the object itself is before it; and, with relation to a second mirror, this image will have all the effect of a real object. Let, therefore, $a\,m$ and $a\,n$ be drawn perpendicular to A C and B C, and produced till $m\,a' = m\,a$, and $n\,a'' = n\,a$; then a' and a'' will be the two first images of the object *a*. Make $a'\,p$ perpendicular to B C, and $a''\,q$ to A C, and let $p\,b' = a'\,p$, and $q\,b'' = a''\,q$; then will b' and b'' be the images of *a* formed by a second reflexion. Again, draw $b'\,r$ perpendicular to A C, and $b''\,s$ perpendicular to B C, and let $r\,c' = b'\,r$ and $s\,c'' = b''\,s$; then will c' and c'' be the images of *a* formed by the third reflexion. But by the geometrical properties of the figure these two points c' and c'' coincide, or the two images are blended together, and the object will be seen in six different places symmetrically arranged in a circular field about the centre C. In like manner, if A B C had been the 8th part of 360°, the object would appear in eight positions, and so on; but if the angle at C, which is the angle of the mirrors, be the 7th or 9th, or any odd aliquot part of 360°, the images will not coincide, and the symmetrical arrangement will not be produced.



The kaleidoscope here described was first made known by Sir David Brewster, who took out a patent for it in the year 1817; but by some means or other its properties were discovered, and it had acquired great popularity as an agreeable toy, and was in the hands of every body before any number of the patent kaleidoscopes could be prepared for sale. It was also very soon remarked that the discovery was by no means new, as an instrument on the same principles had been described by Baptista Porta and Kircher; and also in a work published in England in 1810, under the title of *New Improvements of Planting and Gardening*, by R. Bradley, in which it was recommended as useful for assisting to form designs of garden plots and fortifications. In fact, the principle, so far as the multiplication of images and their general arrangement are concerned, had been long known; but in order to produce the symmetry which constitutes the principal beauty of the kaleidoscope, it is also necessary that the object and the eye have certain positions with respect to the mirrors, and the discovery of this condition seems to belong exclusively to Sir D. Brewster. See *Brewster's Treatise on the Kaleidoscope; Harris's Treatise on Optics; Brewster's Optics. Cab. Cycl.;* the *Ency. Brit.*, &c.

KA'LENDERS. (From an Arabic word signifying

pure gold.) Wandering dervises. (See *Lane's Arabian Nights' Entertainments*.)

KA'LI. An Arabic word, signifying the ashes left after the combustion of vegetable substances; hence the word *alkali*. Potassa is frequently termed *kali*, and potassium *kalium*, by the German chemists; hence they use K as the symbol for potassium.

KA'LMIA. (From Kalm, a traveller in North America.) A genus of beautiful North American plants, with a monopetalous corolla, which confines ten stamens by their anthers in the same number of niches in its sides. The flowers are white or pink, and the leaves evergreen; but the plants are said to be deleterious.

KA'MI. Spirits or divinities, the belief in which appears to have characterized the ancient religion of Japan before it became intermingled with foreign doctrines, and still constitutes its groundwork. These spirits are partly elemental, subordinate to the gods of the sun and moon, and partly the spirits of men; but in fact every natural agent or phenomenon has its spirit or genius. The human spirits survive the body, and receive happiness or punishment for the actions of the individual in life. Distinguished benefactors of their species, or men renowned for purity of life, are deified; and their *kami* become objects of worship, like the heroes of antiquity. The number of them is said at present to be above 3000. They are worshipped in temples in which no images are retained, each particular divinity being merely typified by a mirror, the emblem of purity; and all the rites of the worship appear to be symbolical of purification. The priests of these temples are styled Kami-Nusi, *i. e.* ministers of the spirits. (*Klaproth, Annals of Japan*, 1834; *Wiener Jahrbuch* for 1837.)

KAMIC'HI. The name of a Rassorial or Gallinaceous bird, remarkable for having its wings armed with two strong spurs, and its head with a long, slender, cylindrical and nearly straight horn. *See* PALAMEDEA.

KA'NGAROO. The native name of a large indigenous quadruped of New Holland; it belongs to a genus characterized by a strictly herbivorous modification of the marsupial type of the dental organs, and by a remarkably long and strong tail and hind legs. *See* MACROPUS and MARSUPIALIA.

KA'NTIAN PHILOSOPHY (known also by the name of the Critical Philosophy). A system which owes its existence to Immanuel Kant, professor of logic and metaphysics in the university of Königsberg in the latter half of the 18th century. The promulgation of Kant's doctrines forms a very marked era in the history of philosophy. Our limits will prevent us from giving an explanation of this system in any degree adequate to its importance. We must confine ourselves to a brief outline of its leading features. At the time when Kant commenced his metaphysical labours the philosophical world was divided between the sensualism of the French followers of Locke on the one hand, and the dogmatic rationalism of the disciples of Wolf and Leibnitz on the other. The former, by a species of analytical legerdemain, resolved all our mental powers into modifications of sense; while the latter, in an equally indiscriminating spirit, though with far more laudable intentions, sought to construct a system of real truth out of the abstract conceptions of the understanding. Against both of these schools Kant declared open warfare. Withdrawing himself from all ontological speculation, he sought, by a stricter analysis of our intellectual powers, to ascertain the possibility and to determine the limits of human knowledge. He divides the speculative part of our nature into three great provinces,—sense, understanding, and reason. Our perception of the outward world is representative merely: of things as they are in themselves it affords us no notices. In order to render human experience possible, two ground-forms, under which all sensible things are contemplated, are assumed, —time and space. To these he assigns a strictly subjective reality. The truth of the fundamental axioms of geometry rests on the necessity and universality of our intuitions of space in its three dimensions,—intuitions which are not derived from any one of our senses, or from any combinations of them, but lie at the ground and are the condition of all sensible human experience. The understanding, or the faculty which combines and classifies the materials yielded by sense, Kant subjects to a similar analysis. All its operations are generalized into four fundamental modes or forms of conception; which, after the example of Aristotle, he names categories. (*See* CATEGORY.) These are four in number:—1. Quantity, including unity, multeity, totality; 2. Quality, divided into reality, negation, and limitation; 3. Relation, viz. substance and accident, cause and effect, action and reaction; and 4. Modality, also subdivided into possibility, existence, and necessity. These form, as it were, the moulds in which the rude material of the senses is shaped into conceptions, and becomes knowledge properly so called. The categories in themselves are the subject-matter of logic, which is so far forth a pure science, determinable à priori. The third and highest faculty, the reason, consists in the power of forming ideas,—pure forms of intelligence, to which the sensible world has no adequate correspondents. Out of these ideas no science can be formed: they are to be regarded as regulative only, not as constitutive. The existence of God, immortality, freedom, are the objects after which the reason is perpetually striving, but concerning which it can decide nothing either one way or the other. Thus far Kant's system may be regarded as one of pure scepticism. The deficiencies of our speculative reason he conceives to be supplied by the moral faculty, to which he has given the name of practical reason, the object of which is to determine, not what is, but what ought to be. As the former determines the *form* of our *knowledge*, so the latter prescribes the form of our *action*. Obligation is not a mere feeling; it is a pure form under which the reason is compelled to regard human conduct. The personality of man, which lies at the ground of speculative knowledge, becomes in relation to action freedom of the will. It is in our moral nature that we must seek for the only valid foundation of the belief in God, the immortality of the soul, and a future state in which the demands of the practical reason shall be realized. (See *Kant's Philosophical Works; Kritik der Reinen Vernunft; Kritik der Practischen Vernunft*, &c.)

KA'OLIN. The Chinese name for *porcelain clay*. A large tract of this useful substance occurs near St. Austle in Cornwall, whence our potteries and porcelain manufactories are copiously supplied. Its essential component parts are silica and alumina; the former usually preponderates. The kaolin of Cornwall, and probably of other countries, is derived from the decomposition of the felspar of granitic rocks.

KA'RA. A Tartar word, signifying *black*, used in many of the Eastern languages as a prefix to geographical names; as Karamania, *the country of the black people*. It has also been employed in the same capacity to signify "tributary;" as kara kalpacks, *tributary kalpacks*.

KARMA'THIANS, or KARMATIANS. A Mohammedan sect which arose in Irak during the 9th century of the Christian era. It derived its name from Karmata, its founder, a poor labourer, who assumed the rank of a prophet. They maintained bloody wars with the caliphs for nearly a century. (*Taylor, Hist. of Mohammedanism*, p. 223.; *Secret Societies of the Middle Ages*, Lib. Ent. Kn. 1837.)

KA'RPHOLITE. (Gr. κάρφω, *I dry or shrivel*.) A mineral which occurs in stellated crystals of a yellowish colour and silky lustre: it is a hydrated silicate of alumina and manganese.

KARPHOSIDE'RITE. A mineralogical name of the hydrated phosphate of iron of Labrador.

KEEL. (Probably from the Gr. κοῖλος, *hollow*.) The principal piece of timber in a ship, usually first laid on the blocks in building. If we compare the body of a ship to the human skeleton, the keel seems to resemble the back bone, and the timbers the ribs. It is generally composed of several thick pieces of wood placed lengthways, which after being scarfed together, are bolted and clenched upon the upper side.—*Keelage* signifies the duty paid by a ship on coming into port.

KEEL. In Botany, a name applied in a figurative sense to the two lowest petals of a Papilionaceous corolla, which, together, have some resemblance to the keel of a boat.

KEEL-HAULING. A nautical punishment practised chiefly in the Dutch navy, by which the culprit is let down on one side of the ship, and after passing under the keel is *hauled* up on the other. This punishment was formerly not altogether unknown in the British navy; but it is not now resorted to.

KEE'LING. A name for the common cod (*Morrhua vulgaris*, Cuv.). *See* MORRHUA and GADUS.

KEEP. (Anglo-Sax. kepan.) Applied in ancient Military History to the stronghold of a castle, to which in cases of emergency the besieged inmates retreated, and there made their last efforts of defence. It is almost synonymous with *donjon* (which see).

KEE'PER OF THE GREAT SEAL, LORD, or LORD KEEPER. An officer of high dignity in the English constitution, whose office is created by the delivery of the king's great seal into his custody. He is prolocutor or speaker of the House of Lords by prescription. By 5 Eliz. c. 18. the offices of lord chancellor and lord keeper are declared to be of exactly the same authority; and when there is no chancellor the great seal is ordinarily put in commission. (*See* CHANCELLOR, SEAL. *Bl. Com.* iii. 47.) The keeper of the privy seal is styled lord privy seal.

KEEPING. (Ang. Sax. kepan, *to keep*.) In Painting, the management of the lights, shadows, colours, and aërial tints in such subordination to each other, that each object may seem to stand rightly in the place that the linear perspective has assigned to it. Objects in the nearer parts or foreground of a picture will necessarily receive the strongest lights and shadows; and as more air is interposed in nature between the eye and the objects as they

become more distant, so in the representations of them the colours must be less brilliant as they recede from the eye towards the distance wherein they are lost. This word must not be confounded with the term *effect*, though effect is doubtless the result of keeping in a picture, that word being more peculiarly applicable to the sensation produced by the combination of accidental circumstances in the disposition of light and shade.

KELP. A common term for sea weed or vraic, which consists of different species of *Fucus* (Lin.). In a strict sense, the term kelp is confined to the produce of sea weeds when burned, which consists of alkaline ashes used in the manufacture of glass and soap. It has been recently found, however, that the alkali required for these purposes can be obtained more abundantly from sea-salt, and kelp is at present chiefly used as a manure. For this purpose it is eagerly sought after by all farmers on the sea coast, and especially by those who have dry soils, the salt contained in the kelp being a powerful absorbent of moisture from the atmosphere. It has lately acquired much importance as a source of *iodine*.

KE'NNEL. Applied literally to the house in which a pack of hounds is lodged, but used metaphorically also for the pack itself. It signifies also the spot to which the fox after his nocturnal depredations retires about the dawn of day. Hence, on being found by the hounds in drawing cover, he is said to be *unkennelled*.

KE'PLER'S LAWS, in Astronomy, are the laws of the planetary motions, first discovered and demonstrated by Kepler, and which form the basis of the whole theory of gravitation and physical astronomy. They are three: — 1. That the planets describe ellipses, each of which has one of its foci in the same point, namely, the centre of the sun. 2. That every planet moves so that the line drawn from it to the sun describes about the sun areas proportional to the times. 3. That the squares of the times of the revolutions of the planets are as the cubes of their mean distances from the sun. These three laws or general facts were discovered by Kepler from a comparison of astronomical observations; and though it was by means of them that Newton established the more general law of attraction inversely as the square of the distance, they are themselves direct consequences of that hypothesis. The first law, that of the elliptic motion of the planets, was announced by Kepler in his famous work, *Physica Cœlestis tradita Commentariis de Motibus Stellæ Martis*, 1609. Kepler having computed from the observations of Tycho Brahe the distances of Mars from the sun at different points of his orbit, found that the orbit was not circular, as had always been supposed by astronomers till then, but elliptical; and that the sun occupies one of the foci of the ellipse. He afterwards discovered the same thing to be true of the earth's orbit; and thence extended it by analogy to all the other planets. Newton demonstrated in the *Principia* that if a body projected in space is acted upon by a central force varying inversely as the square of the distance, the body will necessarily describe one of the three conic sections; but whether the orbit will be an ellipse, an hyperbola, or a parabola, depends on the intensity of the force with which it is projected.

Kepler was led to the discovery of his second law by a comparison of the sectors formed by two contiguous *radii vectores* and the angles included between them. The data which he assumed were not rigorously exact; but Newton afterwards demonstrated from the theory of dynamics that the fact is necessarily true of all motions regulated by a central force, whatever the law of that force may be.

The history of the discovery of the third law is remarkable, and detailed by Kepler himself in his *Harmonices Mundi*, lib. v. He had long been persuaded that some numerical relation must exist between the periodic times of the planets and their distances from the sun. In order to discover this relation he tried successively numerous hypotheses, each of which involved a mass of tedious calculation. He began by comparing the intervals between the planetary orbits with the five regular solids; and having failed in this speculation as well as various others, he at length thought of comparing the different roots and powers of the periods and distances. After many attempts and failures, he at last perceived the analogy of which he had been so long in search.

—— "Sera quidem respexit inertem,
Respexit tamen et longo post tempore venit,"

he exclaims; and in the fulness of his delight he has recorded the year and day on which the discovery was made. It was the 15th of May, 1618; and, as Professor Playfair has remarked, "perhaps philosophers will agree that there are few days in the scientific history of the world which deserve so well to be remembered." (*Dissertation*, *Ency. Brit.* See *Kepler's Harmonices Mundi*, p. 189.)

KE'PLER'S PROBLEM. The discovery made by Kepler, that the planetary orbits are ellipses having the sun in the focus which is common to each ellipse, and that the line which joins the centres of the sun and a planet passes over equal areas in equal times, made it necessary to solve a problem which transcended the geometry of that time: — Supposing the semitransverse axis of a planet's orbit to be represented by 1, and the eccentricity by e; also the mean anomaly at any given instant of time by z, and the eccentric anomaly by x, both being reckoned from the perihelion. Kepler found the relation between the angles x and z to be expressed by the equation $z = x - e \sin. x$. When x is given, z is easily found from the trigonometrical tables; but there is no direct way, unless by infinite series, of finding x when z is given, which is the case that occurs in astronomy. The determination of x in terms of z constitutes what is called Kepler's Problem. Solutions of this important problem are to be found in most works on astronomy. They are generally tentative, depending on a combination of geometrical and trigonometrical principles; but two very elegant ones, purely analytical, are given by Professor Wallace, in the *Memoirs of the Royal Astronomical Society*, vol. ix. p. 185. The first of these solutions is as follows: —

1. Find x', a first approximation to the eccentric anomaly x, by this formula,

$$\tan. (x' - \tfrac{1}{2} z) = \frac{1 + e}{1 - e} \tan. \tfrac{1}{2} z.$$

2 Find y such that

$$\tan. (\tfrac{1}{2} x' + y) = \frac{1 + e}{1 - e} \tan. \tfrac{1}{2} x'.$$

3. Find c, a correction of x', so that

$$\sin. (y - c) = \frac{\sin. y}{\sin. x'} \cdot \frac{\sin. 1''}{e} (x' - z).$$

(Here $x' - z$ must be expressed in seconds of a degree.)

4. Then the eccentric anomaly, $x = x' + c$. The computation of the eccentric anomaly by this method is extremely simple.

KE'RATONY'XIS. (Gr. κερας, *a horn*, νυξις, *puncture*.) A term applied by the German surgeons to the operation of couching, performed by introducing a needle through the cornea or horny coat of the eye, and depressing or breaking the opaque lens.

KERI-CHETIB. (Heb.) In Philology, the name given to various readings in the Hebrew Bible. Keri signifies *that which is read*, and Chetib *that which is written*. When any such various readings occur, the false reading or chetib is written in the text, and the true reading or keri is written in the margin, with ק under it. These corrections, which are about 1000 in number, have been generally attributed to Ezra; but as several Keri-chetibs are found in the sacred books the produce of his own pen, it is more probable that they are of later date. (See *Dr. Kennicott's Dissertatio Generalis*.)

KE'RMES. (Arab. *little worm*.) An insect found in many parts of Asia and the south of Europe; the *Coccus ilicis* of Linnæus. They were long taken for the seeds of the tree on which they live, and hence called *grains of kermes*. They are used as a red and scarlet dye, but very inferior to cochineal. Previously to the introduction of cochineal, by which it is now nearly wholly superseded, kermes had been the most esteemed drug for dyeing scarlet from a remote period of antiquity. Cloths dyed with kermes are of a deep red colour; and though much inferior in brilliancy to the scarlet cloths dyed with real Mexican cochineal, they retain the colour better and are less liable to stain. The tapestries of Brussels and other parts of Flanders, which have scarcely lost any thing of their original brilliancy, even after a lapse of 200 years, were all dyed with kermes. (See *Beckmann's History of Inventions*; and *Bancroft's Permanent Colours*.)

KE'RMES MINERAL. A name given by the old chemists to the hydrosulphuret of antimony, in consequence of its reddish colour.

KE'RODON. (Gr. κεαρ, *a heart*, οδους, *a tooth*.) A genus of Herbivorous Rodents, characterized by $\frac{4 \cdot 4}{4 \cdot 4}$ molar teeth, each composed of two equal parts, of which the transverse section presents a cordiform or heart-shaped figure: the two parts are united on the external side in the upper, and on the internal side in the lower jaw. The incisors are two in number in both jaws, and present the form common to the Cavies, to which family the present genus belongs. The species are small, scarcely equalling in size the Guinea-pig. They are peculiar, with the other Cavies, to the South American continent.

KE'RSEY. (Probably a corruption of Jersey, whence it originally came.) A kind of coarse cloth, usually ribbed, and woven from long wool. It is chiefly manufactured in the North of England. *Kerseymere*, on the other hand, is a thin stuff, generally woven plain from the finest wools; and hence it has been inferred that these two terms, whose meaning is so distinct, cannot be referred to the same origin. Kerseymere is said to have derived its appellation from Cashmir, a country which

produces the finest wool, and is consequently most celebrated for the works of its looms. In England it is principally manufactured in the Western districts.

KETCH. (Ital. caicchio.) An old English term, applied to a vessel equipped with two masts, and from 100 to 250 tons burden. It was nearly synonymous with the modern term *yacht*, being used chiefly by ambassadors or other distinguished personages in voyages from one place to another, and was furnished with all the apparatus necessary for defence or aggression.

KE′TCHUP. The juice which exudes from salted mushrooms.

KEU′PER. A term applied by the German geologists to the upper portion of the new red sandstone formation.

KEY. (Sax. cæze.) In Architecture, a piece of wood let into the back of another in the contrary direction of the grain, to preserve the last free of warping.

KEY, or KEY NOTE. In Music, the principal or fundamental note in a composition, on which frequent closes or cadences are made. It is that in which the piece begins and usually ends, and is, as it were, the musical subject to which regard must be had in all the other combinations of sounds in the composition, and under whose influence they are.

KEY-BOARD. In Music, the series of levers in a keyed instrument, as a piano-forte, organ, or harpsichord, upon which the fingers press to produce percussion of the strings, or in the organ the opening of valves. It consists of short black and long white keys.

KEYSTONE. The middle voussoir in the arch of a bridge, or the arch-stone in the crown or immediately over the centre of the arch. The length of the keystone, or thickness of the archivolt at top, is allowed to be about 1-15th or 1-16th of the span by the best architects.

KHALIFF. *See* CALIPH.

KHAN. In Persia, properly speaking, the title of an officer or governor, added after his name. The sovereigns of many independent states of northern Asia are styled Khans. Khan is frequently used by our own countrymen to signify an Eastern caravansera (which see); in which travellers find a gratuitous lodging, provided their stay be limited to a single night.

KHOH. A Persian word signifying *bald*, and used as a prefix in many geographical terms. It has been suggested that the name Caucasus has been derived from Khoh Kasp, or *bald mountain*; i. e. having the summit without vegetation. But be this as it may, it is singular enough that the same metaphorical expression has been introduced into two modern languages, the French and the German; in the former of which is found *Chaumont*, and in the latter *Kahlenberg*, both indicative of a mountain *bald* or without vegetation.

KHO′TBAH (Arab.), denotes a peculiar form of prayer, used in Mohammedan countries at the commencement of public worship in the great mosques on Friday at noon. It was originally performed by the Prophet himself, and by his successors till the time of Mohammed VIII. (A. D. 936), who appointed special ministers for the purpose, on which footing it has continued to the present time. The khotbah is chiefly a "confession of faith," and a general petition for success to the Mohammedan religion. It is divided into two distinct parts, between which the officiating khatib or priest makes a considerable pause, and is regarded by the Mussulmans as the most solemn and important part of their worship. The insertion of his name in this prayer has always been considered one of the chief prerogatives of the sultan of Turkey.

KIDNA′PPING. In Law, the forcible abduction of any one from his own country into another. It is an offence at common law. By the 11 & 12 W. 3. c. 7. penalties were denounced against masters of vessels having aboard persons who had been kidnapped against their will, which was probably occasioned by the practice, not uncommon in those days, of carrying away by force or fraud labouring persons to serve in the plantations in America. This clause is repealed by 9 G. 4. c. 31., by which masters of vessels are made punishable for leaving abroad any of their men against their will, or refusing to take them back if in a condition to return. The stealing of children away from persons having the lawful custody of them (popularly termed kidnapping) is felony under the same statute.

KI′DNEYS. The organs in which the urine is secreted: there is one on each side in the loins, near the first lumbar vertebra, and behind the peritonæum. The pelvis of the kidney terminates in the ureter, and is divided into several portions called *calyces*, into each of which a papilla projects, through the minute orifices of which the secreted urine passes into the cavity called the pelvis, and thence by the ureter into the bladder.

KI′LLAS. A provincial term, applied to the clay-slate rocks of Cornwall.

KI′LLINITE. A mineral, sometimes described as a variety of spodumene, from Killiney, near Dublin. It is a hydrated silicate of alumina, containing potash and oxide of iron.

KILN. A term applied to various furnaces and stoves: as *brick* and *lime kilns*, and *hop* and *malt kilns*. (See those articles.)

KI′LOGRAM. A French measure of weight, equal to 2 lbs. 3 oz. 5 drs. avoirdupois.

KILT. A loose dress, extending from the belly to the knee in the form of a petticoat; worn in the Highlands by men, and by children in the Lowlands. The term is, according to Jamieson, unquestionably Gothic. The Highlanders designate the kilt as the *filibeg*. This singular national dress is fast hastening into disuse; and but for a few Highland regiments in which it is still maintained, it would probably long ere now have been universally superseded by the dress of the Lowlanders.

KING. A title of dignity in the languages, extinct and living, of the Gothic and Teutonic races. The term has long been considered of uncertain origin; but there can be little doubt that it is derived from the German word können, *to be able*, thus in the very threshold giving an idea of superior power or ability. In its primary acceptation it denotes a person in whom is vested the chief executive authority; but it is susceptible of as great a variety of shades of meaning as there are states or nations to be governed. Thus it is applied equally to the limited sovereign of England and the absolute sovereign of Prussia; to the chief magistrate of Poland in former times, who was *elected*, and to that of England, who succeeds by *hereditary* right; to the head of a savage tribe or barbarous horde, as well as to that of the most refined and civilized nation. It is expressed in Greek by the word Basileus, and in Latin and its cognate languages by Rex; but all the nations of Europe have adopted into their respective languages the equivalent terms in use among the people with whom they carry on intercourse. Thus we speak of the Shah of Persia, the Grand Sultan, the Pasha of Egypt, the Dey of Algiers, &c.

In countries where the kingly office is hereditary some form has always been gone through on the accession of a new king, in which there is a recognition on the part of the people of his right; a claim from them that he should pledge himself to the performance of certain duties; and generally a religious ceremony performed, in which anointing him with oil, by which a certain sacredness is thrown around his person, and placing a crown upon his head as a symbol of supremacy, are conspicuous acts. (*Penny Cyclop.*) The whole solemnity is styled the coronation. In modern Europe the Pope and the Emperor of Germany assumed as a joint prerogative the right of conferring the dignity of king. Frederic I. of Prussia was the first sovereign who assumed the title, and had it acknowledged by the other states of Europe without their authorization.

KING. The sacred books of the Chinese, containing at once the principles of their domestic and public morality and the foundation of their historical traditions. According to a learned dissertation by M. Freret, in vol. xv. of the *Memoires de l'Ac. des Inscr. et Belles Lettres*, the original books known properly under this title are only four in number; but those commonly so designated amount to thirteen, which are published together. The first four contain the writings of Confucius. (See also vols. xxxvi. xxxviii.; and *Ersch and Gruber's Encyclopedia.*)

KING AT ARMS. An officer of great antiquity, and formerly of great authority, whose business is to preside over the chapters, and to direct the proceedings of heralds. The origin of this office is involved in obscurity. There are three kings at arms in England — Garter, Clarencieux, and Norroy; the first of whom is styled *principal king at arms*, and the two latter *provincial kings*, because their duties are confined to the provinces. The name Clarencieux is said to be derived from Clarence, brother of Henry V., first king at arms for the south of England; that of Norroy (Norman French for *northern king*) is self-explanatory. There is also a Lyon king at arms for Scotland, as well as an Ulster king at arms for Ireland, whose duties are nearly analogous to those of England. (See *Noble's History of the College of Arms.*)

KING, THE, OF ENGLAND, exercises the supreme executive power, together with a share in the legislative authority jointly with the two Houses of Parliament. (For his legislative functions, *see* PARLIAMENT.) The right to the throne of England (now extended to Great Britain and Ireland) is hereditary, subject to the authority of parliament to limit the succession. This was last done by the stat. 12 & 13 W. 3., when it was fixed in the heirs of the electress Sophia of Hanover, being Protestants. The duties of the king according to the constitution are embodied in the coronation-oath, fixed by stat. 1 W. & M. Incidental prerogatives are legal exceptions in favour of the crown where its claims clash with those of a subject; relating to such matters as descents of land, debts, &c. The direct prerogatives of the crown are those which attach to his person in respect of his political authority: such as the sanctity of his person;

his prerogatives as head of the executive; the power of making war and peace; treaties with foreign powers; military and naval command; the supreme dispensation of justice through his courts; the power of erecting and disposing of offices and honours; the power of issuing proclamations binding on the subject in certain cases, with the advice of his privy council; and, lastly, the supreme government of the national church. The king's revenue is of two sorts, ordinary and extraordinary. The ordinary revenue or patrimony is such as either has subsisted in the crown time out of mind, or has been granted by parliament in exchange for such. (*See* Civil List.) The extraordinary revenue consists of the supplies annually granted by parliament. *See* Parliament, Prerogative.

KING CRAB. *See* Limule.

KING FISH. A name sometimes applied to the *opah* (*Lampris guttatus*, Retz.).

KING POST. In Architecture, the middle post of an assemblage of trussed framing for supporting, or rather suspending, the tie beam at the middle and the lower ends of the struts.

KING'S BENCH, COURT OF, in Law, originated in the ancient Aula Regia, in which the king was accustomed (as he still is supposed in the King's Bench by fiction of law) to sit in person, and which followed him in all his progresses. The judges of the court of King's Bench, as well as of the other superior courts, formerly varied in number according to the royal discretion. At a later period they were reduced to four; now increased, by stat. 1 W. 4. c. 70., to five — the chief justice, who is the highest common law judge, and four *puisné* or *younger* judges. The court of King's Bench, besides those branches of its jurisdiction which it has in common with the other two superior common law courts (*see* Courts, Superior), has also peculiar authority, or presents more advantages in some particular proceedings.

It is the preferable although not the only tribunal for discharging prisoners under the Habeas Corpus Acts. It has controul over all inferior courts by means of the process called *certiorari*, which is a writ sued out of this court, by virtue of which proceedings may be removed into it out of such inferior jurisdiction, whether in criminal or civil cases. It has also an exclusive authority (except in a few cases) to compel all inferior courts and officers, and in some instances private persons, to perform acts of a public nature, and connected with a public duty. By means of a *prohibition* it can restrain all other courts from proceeding where they exceed or misuse their jurisdiction: this is likewise a writ directed to the judge and the plaintiff in the inferior court. A writ of error in law from all *inferior courts* is, with certain exceptions, returnable in the King's Bench. This court likewise hears and determines cases stated by courts of sessions. The greater proportion of these are questions on the validity of poor's rates, or on parochial settlements. When a court of sessions entertains a doubt on a point of law arising in the argument, it will usually authorize the party against which it decides to have the judgment thus reviewed, the cases being stated in writing. The criminal jurisdiction of the King's Bench is still extensive. It has, at common law, jurisdiction by indictment over every species of criminal offence committed in Middlesex; and in practice misdemeanors, as conspiracies or perjuries, committed in the county, are still indicted in this court, and tried after term at nisi prius among the civil causes. Sometimes also trial at bar, or by the full court, is granted on special application. It has also jurisdiction by criminal information, which lies in cases of misdemeanor only; a proceeding which supersedes the necessity of an indictment found by a grand jury. An information is filed either by the attorney-general *ex officio*, as it is termed, — a proceeding generally adopted in certain misdemeanors of a public nature; or at the suit of a private party, by leave of the court.

An information in the nature of a *quo warranto* is in form a criminal, but substantially a civil, proceeding. It is granted where any subject or body politic has assumed a franchise or privilege not being legally entitled, and to the injury of some other party or the public. Any indictment, presentment, &c. found in any part of England, may be moved by *certiorari* into this court; as may be also all convictions or orders of justices of the peace, unless where such appeal is prevented by particular statutes.

KING'S EVIL. Scrofula attacking the glands, respecting which a superstitious notion long existed that it was curable by the touch of royalty.

KI'NGSTON. A name sometimes given to the angel-fish (*Squatina angelus*, Dunn.). *See* Squatina.

KING'S YELLOW. A pigment, the basis of which is *orpiment*, or yellow sulphuret of arsenic.

KI'NIC ACID. The acid with which quinia and cinchonia are combined in yellow and pale Peruvian bark. Its ultimate elements are, according to Lubig, 15 atoms of carbon, 9 of hydrogen, and 9 of oxygen.

KI'NKAJOU. The native name of a Plantigrade quadruped of South America, of arboreal habits, with a long prehensile tail, a short muzzle, and a thick coat of woolly hair. It forms the type of the genus *Potos* of Cuvier, which name Illiger changed to *Cercoleptes*. Only one species is well established, the *Cercoleptes caudivolvulus* of Illiger.

KI'NO. An Indian word, applied to an astringent vegetable extract, the source of which is doubtful; it is probably a name given to the products of different plants in Africa, and in the East and West Indies and America. The finest kino is in brilliant fragments of a deep brownish red colour, and highly astringent: it contains tannin, gum, and extractive matter.

KIOSK. A Turkish word, signifying a kind of open pavilion or summer house, supported by pillars. These ornaments have of late years been introduced to a considerable extent into the gardens of European countries.

KIRK. (Germ. kirche.) A Scottish term synonymous with church, and used chiefly to designate the form of religion established in that country. *See* Presbyterianism.

KIRK SESSION. The lowest ecclesiastical court of the kirk of Scotland. It is composed of the minister of the parish, and of lay elders. It takes cognizance of cases of scandal, of the poor's fund, and of matters of general ecclesiastical discipline. There is an appeal from its decisions to the presbytery.

KI'RSCHWASSER. (Germ. *cherry water*.) An alcoholic liquor, obtained by fermenting the small and sweet black cherry. The liquor produced is distilled, and often flavoured with hydrocyanic acid, derived from the bruised kernels of the fruit: this gives to kirschwasser, when sweetened, the character of noyau.

KIT CAT CLUB. The name of a celebrated association, instituted about 1688 by "some young men of wit and pleasure about town," originally for convivial purposes; but as its most distinguished members were Whigs in politics, it gradually assumed a political character, till in the reign of Queen Anne it came to be regarded as exclusively political in its objects. At that period it comprised above forty noblemen and gentlemen of the first rank and quality, merit and fortune, firm friends to the Hanoverian succession; among whom were Addison, Steele, Marlborough, Walpole, &c. &c. It was originally formed in Shire Lane, and derived its name from one Christopher (Kit) Kat, who supplied the members with mutton pies. The fame of this club has been transmitted chiefly by the collection of the portraits of the members painted by Sir Godfrey Kneller, himself a member, who was obliged to invent a new-sized canvass accommodated to the height of walls; whence has originated the application of the epithet *kit cat* to any portrait about three quarters in length. It was dissolved in the year 1720. (*Quart. Rev.* vol. xxvi.)

KITE. A well-known toy; first employed by Romas in France, and Dr. Franklin in America, to elevate a conductor into a thunder-cloud, whereby the identity of lightning with the electric spark was ascertained. It is formed of a slender frame of wood and pack-thread, rounded at one end and terminating in a point at the other, resembling in some measure a cross-bow, and covered with paper. A long string is attached to the frame, near its centre of gravity, by which it is held in the hand. In order that the kite may be capable of being raised, it is necessary that its flat surface be presented obliquely to the direction of the wind; a string or *tail*, carrying some light substance, is therefore attached to the sharp end of the frame, and serves by means of its gravity to maintain the proper inclination. The force of the wind, impinging obliquely on the surface, is resolved into two parts; one perpendicular and the other parallel to the surface: the first of these parts is counterbalanced by the tension of the string held in the hand, and the second is expended in elevating the kite. The position in which the wind acts with the greatest effect is when the perpendicular to the surface is inclined to the direction of the wind (that is, to the horizon) in an angle of about 54½ degrees.

Kite. The native bird so called is a species of the genus *Milvus*, separated by Bechstein from the genus *Falco* of Linnæus on account of the forked tail, length of wings, and the short and weak beak and feet in proportion to the size of the body. This deterioration of their destructive instruments renders the kite the most cowardly of the birds of prey. The common kite, or glead (*Milvus vulgaris*), preys chiefly on the smaller quadrupeds and birds, young chickens, &c.; yet the courage of the mother hen renders her more than a match for the robber, and she generally repels his attacks on his favourite prey. The female lays two or three eggs of a whitish colour, spotted with pale yellow, and of a roundish form.

The term *kite* is applied in some places, as Devonshire and Cornwall, to the brill (*Rhombus vulgaris*).

KI'VI-KIVI. The native name of the New Zealanders for their singular bird the *Apteryx australis*. *See* Apteryx.

KNEE. (Sax. cneo.) In Architecture, a naturally or artificially bent piece of timber, on which another is received to relieve a weight or strain.

KNEE PAN. A small flat heart-shaped bone placed

at the fore part of the knee joint. It is an important defence to that large joint, and also serves to increase the powers of the muscles which extend the leg. It is attached by a strong ligament to the upper end of the tibia.

KNIGHT-ERRANT. In the language of Chivalry, a knight wandering in search of adventures, sometimes under vows, for a certain period. Knight-errantry was not altogether a fiction of romance. It originated, as Mr. Turner says, partly from the frequency of private war in feudal times, which made military aid constantly acceptable to the great barons; and as a knight had, for the most part, no other tie to the soil than his duties towards his feudal superior, he was at liberty to follow his own bent whenever his services were not needed by him. Such a mode of life peculiarly suited the tastes of the men of that age, and in some degree served the exigencies of society. "Knights, therefore, were perpetually errant, or travelling in quest of adventures or employment: some from the pleasure of the expedition, and some for its expected profits. They often met the oppressed or the unsuccessful; and they cheerfully engaged themselves to redress those wrongs which laws were too feeble to remedy, and for redressing which honour, plunder, or rich donations became usually their compensation." (*Turner's Hist. of England during the Middle Ages*, ch. xiii.)

KNIGHT, KNIGHTHOOD. The word knight is undoubtedly derived in its first origin from the root "to knit," or connect; from whence also the German knecht, *slave* or *servant*. The Anglo-Saxon cnicht bore the same meaning; and this etymology points to the primitive meaning of the institution of knighthood. This may be found in the usage recorded by Tacitus and other writers of the ancient Germans, among whom the kings and chiefs were attended in war and peace by a select body of faithful companions. Kings, and great thanes, and aldermen had each among the Anglo-Saxons their attendant cnichts or military servants, who owed them a species of fealty rather personal than territorial. But the order of knighthood, in the more recent sense of the word, was introduced among us from France. Among the French and Germans, indeed, the order of knights was designated by another name — *chevalier* or *ritter*, from their serving on horseback in battle, and holding a rank above the footmen. But the Norman chevalier so completely answered to the Saxon cnicht in the peculiar attribute of being personally attached to the military service of some chieftain, that the English appellation was soon in general use, as if to express the same meaning conveyed by the French title, and by its Latin equivalent miles. The Saxons appear, indeed, to have occasionally practised, long before the Conquest, some ceremonies resembling those which became usual in later times on the creation of a knight; thus Alfred is said to have honoured Athelstan by the gift of a belt and robe, and girding him with a sword.

Like most other inquiries into the ancient usages of Europe, that into the origin of knighthood as an order, — that is, the period when the term miles or chevalier, instead of merely denoting the higher class of military companions of a chief, came to signify one enjoying a definite rank in society and admitted by certain ceremonies, — is altogether inconclusive. It is said in general that knighthood had become an established institution in the 11th century; but that the characteristic which belonged to it in later times, that of being restricted to men of noble birth, did not become general until the fourteenth. The privilege of conferring knighthood seems to have belonged originally to the sovereign, and to have been retained as his prerogative in all European constitutions, although frequently delegated to or usurped by high feudatories, generals of armies, &c.; although in later times, and when knighthood had assumed its peculiar romantic character, the most distinguished and valorous knights were allowed to confer it, and kings themselves sought for the distinction of knighthood at their hands. It was a prerogative of high value and importance; and we frequently find the states and other authorities in feudal sovereignties interfering to limit its exercise, especially before usage had absolutely restricted it to those of noble birth.

It was common to create knights on various occasions. The most honourable species of knighthood was that conferred on the field and after a battle; but the more common fashion, especially in France, the parent country of chivalrous institutions, was to make knights when a battle was expected. Five hundred were created at once in the French army before the battle of Agincourt. Some inconvenience attended this practice. For example, on one occasion in Flanders, in the 14th century, when two armies were ranged in battle order, on the eve of engagement, the French, according to their usual practice, created a great number of knights; but on the following morning the forces separated without coming to action. A hare having been seen crossing the space between the armies, the French knights made on that occasion received the nickname of Chevaliers du Lièvre. Knights were also created on other solemn occasions; as great festivals, coronations, princely marriages, &c.

In describing the ordinances of knighthood as they existed when that institution was brought to the point of imaginary perfection, the period to which we must refer is the 14th century; and the countries chiefly France, Germany, and England. In Italy and Spain, and generally in other parts of Christendom, the chivalrous customs of the first-named regions were imitated, but do not appear to have grown up spontaneously as part of the popular usages. Before this epoch, indeed, the Crusades had communicated to the institution much of its religious character; and the poems of the Troubadours and Trouveurs attest how much of gallantry had already been fancifully interwoven with the military habits of the age. But it was not, perhaps, until the epoch alluded to, when the favourite fictions of romance had begun to act strongly on the popular imagination, that the ideal usages of chivalry were completely engrafted in practice on the substantial institution of knighthood.

The orders of chivalry were three. The future knight was first educated, in general, as a page attached to the family, and especially to the ladies of some noble house: when of full age, he became a squire (écuyer). The proper office of the squire, in the theory of chivalry, was, as his name of "shield bearer" denotes, to attend on the person of a knight, to whom he was bound to render devoted and faithful service. In this capacity he was a sort of apprentice to knighthood; but as many esquires never reached the order of knighthood at all, but remained independent, the rank of esquire, in ordinary usage, became an intervening order between the knight and the simple gentleman: in which sense it is still retained in England. The order of knighthood followed this double probation. Knights, however, were often made without having passed regularly through the intervening stages; and even in the age of chivalry, the honour was occasionally conferred on mere children; although this was an evident abuse, and regarded as such. When the order of knighthood was conferred with full solemnity in the leisure of a court or city, imposing preliminary ceremonies were required of the candidate. He prepared himself by prayer and fasting, watched his arms all night in a chapel, and was then admitted with the performance of religious rites. Knighthood was conferred by the *accolade*, which, from the derivation of the name, should appear to have been originally an embrace; but afterwards consisted, as it still does, in a blow of the flat of a sword on the neck of the kneeling candidate. The oath of knighthood was previously administered, which contained at different times various fanciful clauses: in France there were twenty vows comprised in it. (See on this subject, among many other authorities, the *Memoirs on Chivalry* of the French antiquary Sainte-Palaye.)

Knighthood was an institution which served in some respects as a compensation for the inequalities of rank incident to the feudal system. All knights, from the king to the lowest bachelor, were brethren of the same order; and when chivalry was in its most flourishing state, it may almost be said that they were all of the same country. National distinctions had little place between knights, who were only enemies in time of warfare, from their feudal duties, which attached them to the banner of a particular king or suzerain. At tournaments, court festivals, &c., in time of peace, knights of all nations were admitted indifferently; and the candidate for knighthood sought that honour at the hands of the most distinguished name in chivalry rather than of a countryman. The chief distinction of rank which subsisted between knights, in France and England, was rather of a feudal than a chivalrous character; it was that of knights-bachelors and knights-bannerets. The knight-bachelor was of the lower order. His name has been variously derived. It is by some considered as a corruption of "bas-chevalier;" but others deduce the name from the barbarous Latin word "baccalare," said to signify a small fief, such as was originally considered as entitling its possessor to the honour of knighthood. But in the more chivalrous times (as in all later periods) this honour was conferred without any reference to a qualification of property. Many knights-bachelors were in fact mere adventurers, unconnected by feudal ties of any sort; who offered their services in war to any successful leader, and who found in their sword a means of subsistence, not only by pay and plunder, but by the regularly established system of ransom which every knight taken in action paid for his liberty. The "chevalier-banneret" was one who possessed fiefs to a greater amount, was obliged to serve in war with a greater attendance, and carried a banner. Under Charles VII. the bannerets of France made remonstrances against the services required of them, on the ground of their impoverishment by the English wars; and it appears that this order fell afterwards into disuse in that country. In England the distinction appears to have been of a somewhat different character. The "knights' fees," into which England was divided by the Conqueror, were such portions of land as could maintain a simple knight or

bachelor; and by a statute of Edward II. persons who had the amount of 20*l.* a year in fee, or for life, were obliged to take this order of knighthood. This statute grew into disuse, except when occasionally put in force, as it was for the last time under Charles I., as a means of extorting money, by way of fines, for not taking up the order. Bannerets, on the other hand, in England, appear to have been such knights as were made or promoted from the lower degree on the field of battle. (*See* BANNERET.) The distinction in the field between the different orders of chivalry was, at least at one period, the following: — The esquire bore the *pennoncel* or triangular streamer; the knight-bachelor the *pennon* or forked streamer (swallow-tailed), made by dividing the end of the pennoncel; the banneret a banner (which was, in strict usage, of an oblong shape, barons being entitled to the square banner). Thus, when a banneret was made on the field, the ceremony was accomplished by cutting off the forked end of his pennon and converting it into a banner. Common knights and esquires were then under his command.

The confinement of the order of knighthood to men of noble birth (on the Continent, for the strict line of demarcation between nobility and commonalty was never accurately drawn in England), although necessary in theory to the completion of the chivalric system, tended in practice to its decay. Knighthood, after the 14th century, became more and more an honorary distinction, to which birth alone gave a title, and which was not considered to represent any actual duty or service; and finally, through various steps, it became again a mere personal distinction, which it was part of the sovereign's prerogative to confer, either to military persons or any others; and by the multiplication of orders, into which nobility of birth was not always a necessary qualification for admission, this peculiar property of the knightly order became again effaced. There are, however, in most Continental countries, several orders into which nobility still constitutes a necessary title for admission.

Orders of knighthood are of two classes: either they are associations or fraternities possessing property and rights of their own as independent bodies, into which knights are admitted as members into a religious foundation; or they are merely honorary associations, established by sovereigns within their respective dominions, consisting of members whose only common tie is the possession of the same titular distinction. To the former class belonged the three celebrated religious orders founded during the Crusades, — Templars, Hospitallers, and Teutonic knights; which were societies, not belonging to any particular crown or realm, possessed of extensive property, and acting in some respects as independent republics. (See those articles.) Several of the Spanish and Portuguese orders of knighthood partake of both characters: they were originally religious, but have become secular. The kings of those countries, as grand masters, exercise the privilege of admission, and make use of it as a means of conferring distinction; but the knights, as a body, form an independent society possessed of property and privileges. (*See* ORDERS of CALATRAVA, ALCANTARA, &c.) The other class, consisting of orders merely titular, embraces most of the European orders, including all those of our own country. These were probably founded in imitation of the great military societies; although antiquarians have traced real or imaginary orders of knighthood under the reigns of princes of much more remote date, as Charles Martel, Charlemagne, &c. But these accounts are apocryphal; and no subsisting order of knighthood is of the date of the Crusades, except a few of those in Spain and Portugal, which, as we have said, were framed on the model of the great societies first mentioned. (See as to foreign orders of knighthood, the work of Carlisle, 1839.)

KNIGHT OF THE SHIRE, is the designation given to the representative in parliament of English counties at large, as distinguished from such cities and towns as are counties of themselves (which are seldom if ever called shires); and the representatives of which, as well as the members for other cities and towns, are called citizens or burgesses. It was formerly imperative on knights of the shire, as well as their choosers, either to be resident or to have a household in the county; but this regulation, which had long fallen into disuse, was formally repealed by 14 Geo. 3. c. 58.

KNIGHT SERVICE, *Servitium Militare.* The tenure by which a knight held his land. *See* FEUDAL SYSTEM.

KNIGHT'S FEE, *Feodum Militare.* In the language of English feudal usage, a portion of land held by custom sufficient to maintain a knight to do service as such for the king. William the Conqueror by his military grants is said to have created 60,000 such fees. But although William's vassals were undoubtedly bound to follow him to war, it is doubted by modern antiquarians whether feudal services, strictly so called, were attached to these grants by the Conqueror, or whether they were not peculiarities arising subsequently when the feudal system grew into vigour, and attributed to the Conqueror by the legists of later times.

KNOLL. A term used in many parts of England for the pinnacle of a small hill, or for the hill itself.

KNO'PPERN. A species of gall-nut or excrescence formed by the puncture of an insect upon several kinds of oak. They are flat, hard, and prickly: they abound in Croatia, Styria, Sclavonia, and Natolia, and are used in Austria and Germany for tanning and dyeing.

KNOT. *See* LOG.

KNOUT, THE. An instrument used in the infliction of a well-known Russian punishment. The following description is by a writer in the *New Monthly Magazine* for 1830 (vol. xxviii. p. 128.): — "The handle may be two feet long, a little more or less, to which is fastened a flat leather thong about twice the length of the handle, terminating with a large copper or brass ring; to this ring is affixed a strip of hide about two inches broad at the ring, and terminating, at the end of two feet, in a point. This is soaked in milk, and dried in the sun to make it harder; and should it fall, in striking the culprit, on the edge, it would cut like a penknife. At every sixth stroke the tall is changed. In the hands of a stranger it would be a most innocent weapon; nor could I, after a quarter of an hour's practice, make any considerable impression on the snow, while the executioner will leave a pretty fair mark on a deal plank." Notwithstanding the assertion of Dr. Granville to the contrary (*Travels to St. Petersburgh*, ii. 451.), there is no doubt of the excessive severity of the punishment.

KOA'LA. The native name of a Marsupial quadruped of New Holland. (*See* PHASCOLARCTUS.) The Mahrattas apply the same name to the jackal.

KO'BOLD. A German word signifying a spirit, or spectre, and corresponding to the English *goblin*, of which it is probably the origin. In many parts of Germany there is scarcely a house or a family to which kobolds are not said to be attached; and according to the superstitious notions of the peasantry, they preside over all domestic operations, many of which they perform. The name of the metal *cobalt* is derived from the above.

KOLPO'DES, *Kolpoda.* (Gr. κολπωδης, *sinuous.*) The name of a genus of Polygastric Infusories, characterized by their flat and sinuous figure.

KO'RAN. *See* ALCORAN.

KOSSACKS. *See* COSSACKS.

KOU'MISS, or KUMISS. A vinous liquid, obtained in Tartary by fermenting the whey of mares' milk.

KO'UPHOLITE. (Gr. κουφος, *light*, and λιθος, *a stone.*) A species of zeolite or prehnite from the Pyrenees: it occurs in small rhomboidal plates, of a pearly lustre, and of a yellowish or green colour.

KRAAL. The name given to the villages of the Hottentots.

KRA'KEN. A name applied in the fabulous epoch of zoology to a marine monster of gigantic size.

KRAMERIA'CEÆ (Krameria, one of the genera), is a small natural order of plants, allied to *Polygalaceæ*, and chiefly remarkable for the extreme astringency of their roots; one of the species furnishing the rhatany or rhatanhia root of the druggists, a substance notoriously used in the adulteration of port wine.

KRAME'RIC ACID. An acid obtained from the root of the *Krameria triandria*, or rhatany.

KREOSO'TE. *See* CREOSOTE.

KRY'OLITE. (Gr. κρυος, *ice*, and λιθος, *a stone.*) A hydrated fluate of alumina and soda. When heated it suddenly fuses; hence its name.

KRY'STALLINE. A term applied by Unverdorben to a salifiable base which forms crystallizable compounds with the acids, and which he obtains from animal empyreumatic oil.

KU'FIC. An epithet given to the ancient Arabic characters; from Kufa, a town on the Euphrates.

KU'PFERNICKEL. (Germ.) An ore of nickel of a copper colour.

KU'PFERSCHI'EFER. (Germ. *copper slate.*) A term applied by German geologists to certain laminated rocks at the base of the magnesian limestone formation of Thuringia: they are impregnated with copper, and abound in fossil remains of fishes. These rocks appear to correspond to the marl slate of Durham and Northumberland.

KY'ANITE. (Gr. κυανος, *blue.*) A mineral which occurs in long radiated crystals, and occasionally massive; it is the *disthene* of Haüy, and the *sappare* of some other mineralogists. *See* CYANITE.

KYRIOLO'GICAL, or CIVIOLOGICAL. (Gr. κυριος, *proper;* λογος, *discourse.*) A term applied by Warburton, in his *Divine Legation* (book ii. s. 4.), to that class of Egyptain hieroglyphics in which a part is conventionally put to represent a whole — *e.g.* a pair of armed hands for a battle, a scaling ladder for a siege, &c.; distinguished from the *tropical*, in which visible objects are used as emblems, or figuratively. *See* HIEROGLYPHICS.

L.

L. The first of those letters in the English and most other alphabets called liquids or semivowels; because, like vowels, they can be pronounced for any length of time, which is not the case with the consonants called mutes, as *p*, *d*, &c. It is derived from the Greek lambda, or the Hebrew or Phœnician lamed, and is found in the languages of almost all nations, excepting those of some Brazilian and Japanese tribes. In the ancient Greek, Hebrew, Phœnician, Celtic, and Latin languages, and in those derived from them, the letter L consists invariably of two strokes, though in every possible shape and combination. Thus, in the most ancient Greek alphabets it is written Λ V Λ, in the Etruscan >, in the Celtic < V, in Hebrew ל, and in Latin L. (For the interchanges which this letter has undergone, see the *Penny Cyclo.*) L, as an abbreviature, stands for Lucius, L. L. D. Doctor of Laws, and L. L. S. for a sestertium. As a numeral, L represented among the ancients, as at present, the number 50, according to the line—

Quinquies L denos numero designat habendos.

LA. In Music, the syllable by which Guido denoted the last sound in the hexachord.

LA'BADISTS, or LA'BBADISTS. A sect of religious enthusiasts in the 17th century; so called from Jean Labadie, a native of France domiciled in Holland, who was deposed from his preachership by the synod of Dort. They endeavoured to introduce among Protestants similar notions to those of the Quietists in the Roman Catholic church (see that word), and were accused of similar perversities in practice. (See *Mosheim*, transl., ed. 1790, v. 511.)

LABARRA'QUE'S DISINFECTING LIQUID. A solution of carbonate of soda impregnated with chlorine.

LA'BARUM. The standard of Constantine, which he caused to be formed in commemoration of the vision of the cross in the heavens. It is described as a long pike surmounted by a golden crown inclosing a monogram which contains the two first letters of the name of Christ, and is at the same time a representation of the figure of the cross. Ancient monuments exhibit the figure under two forms, ☧ or ☧ (*sc.* χ, ρ). The silken banner which depended from it was embroidered with the figure of Constantine and his family. The labarum is engraved on some of his medals with the famous inscription,

EN ΤΟΥΤΩΙ ΝΙΚΑ;

and it was preserved for a considerable time, and brought forward at the head of the armies of the emperor on important occasions, as the palladium or safeguard of the empire. The origin of the word is still undecided. (See Beugnot, *Hist. de la Destruction du Paganisme en Occident*, i. 57.; Milman, *Hist. of Christianity*, ii. 152.)

LA'BDANUM, or LADANUM. The resin of the *Cystus Creticus*.

LA'BEL. In Heraldry, a figure chiefly used by way of distinction or difference in the coat-armour of an eldest son during the life of the father; in which case it has three points; five points when borne by the heir-presumptive of a grandfather living, and so forth.

LABE'LLUM. (Lat.) A term given to the lower lip of a labiate corolla. It is usually differently formed from the other divisions of the corolla, and in the natural order *Orchidaceæ* assumes various grotesque appearances.

LA'BIALS. (Lat. labium, *a lip*.) The letters B, P, V, F, M, are so called, on account of the organ chiefly employed in their pronunciation.

LA'BIA'TÆ, or LAMIACEÆ. A natural order of Monopetalous Exogenous plants, consisting of many hundred species, inhabiting the more temperate regions of the earth. A two-lipped monopetalous corolla, an irregular number of stamens, and a four-lobed ovary, are the essential marks by which it is known from all others. The species are generally herbaceous, with square stems; a small number only consists of shrubs. The flowers are all colours, but pure blue is uncommon in the order. Many of the species are valued for their fragrance, as lavender and thyme; others for their stimulating qualities, as mint and peppermint; some as aromatics, as sage, basil, and marjoram; while a few are regarded as febrifuges. Numerous species are objects of great beauty, on which account the order is well known in gardens. Among the most ornamental are various kinds of sage, gardoquia, and dracocephalum.

LA'BIUM (Lat. labium, *a lip*), in Entomology, is a moveable organ, often biarticulate, which, terminating the face anteriorly, covers the mouth from beneath, and represents the under lip.

LA'BORATORY. A place properly constructed and fitted up for the purpose of carrying on chemical investigations. Those who are about to fit up a chemical laboratory will do well to consult the first section of *Mr. Faraday's Chemical Manipulation*.

LA'BOUR. (Lat. labor.) In Naval language, the action of a ship in a heavy sea when she jerks or is *uneasy*.

LA'BOUR. *See* POLITICAL ECONOMY.

LA'BOURED. In the Fine Arts, a term applied to works of art wherein are apparent the marks of constraint in the execution; and used in opposition to the term *easy* or *free*.

LA'BRADORITE. Labrador spar. A beautiful variety of opalescent felspar from the coast of Labrador: it exhibits brilliant and mutable tints of blue, red, green, and yellow, and is susceptible of a good polish. It is cut into small slabs, and employed in ornamental jewellery. It is a silicate of alumina, lime, and soda, with traces of oxide of iron.

LA'BRAX. (Lat.) A genus of Percoid fishes, dismembered by Cuvier from the Linnæan *Perca* on account of certain modifications of the gill-covers and tongue; the differences being that the opercula of the *Labrax* terminates in two spines, and the tongue, instead of being smooth, is roughened with many minute teeth.

LA'BRIDANS, LABRIDÆ, or LABROIDES. The Bream tribe. A family of Acanthopterygii, having the genus *Labrus* as the type. The fishes of this family may be recognized by their oblong scaly body; a single dorsal fin, supported in front by spines, each of which is generally furnished with membranous appendages: the jaws are covered with fleshy lips, and the pharyngeal bones are armed with numerous and strong teeth, disposed like a pavement.

LA'BRUM (Lat. labrum), in Entomology, is the usually moveable part which, terminating the face anteriorly, covers the mouth from above, and represents the upper lip.

LA'BRUS. (Lat. labrum, *a lip*.) A genus of spiny-finned fishes in the system of Cuvier, so called on account of their well-developed double fleshy lips. The fishes of this genus are termed "breams;" and are further characterized by their conical maxillary teeth, of which the middle and anterior are the longest, and by their cylindrical and obtuse pharyngeal teeth, which are arranged like a pavement, — the upper ones on two large plates, the lower ones on a single one, which correspond with the two others.

LA'BYRINTH. (Gr. λαβυρινθος.) Literally a place, usually subterraneous, full of inextricable windings. Ancient history gives an account of four celebrated labyrinths; the Cretan, Egyptian, Lemnian, and Italian. The first was built by Dædalus at the instigation of Minos, to secure the Minotaur; the second is said to have been constructed by Psammetichus, king of Egypt; the third was on the island of Lemnos, and was supported by columns of great beauty; and the fourth was designed by Porsenna, king of Etruria, as a tomb for himself and his successors. Of these labyrinths the Cretan is most celebrated in the historical and mythological writings of antiquity; but the Egyptian was by far the most important, both in extent and magnificence. The latter, which was built on the isle of Meroe, was a vast edifice, composed of twelve palaces, all contained within the compass of one wall, and communicating with each other. It had only one entrance; but the innumerable turnings and windings of the terraces and rooms of which it consisted rendered it impossible for those who had once entered within its walls to get out without a guide. It is said to have been designed either as a burial-place for the Egyptian kings, or for the preservation of the sacred crocodiles, the chief objects of Egyptian idolatry. It was partly demolished between the reigns of Augustus and Titus; but even at the period of Pliny's visit, its ruins were magnificent. (*Pliny*, lib. xxxv.) *Pococke's History of the East* (vol. i. p. 61. &c.), and *Perry's View of the Levant* (p. 381.), contain a plan and description of the modern state of this labyrinth. With regard to the labyrinth of Crete, no doubt can now remain, after the statements of Cockerell and Tournefort, that its existence was a reality, and not merely a fabulous creation of the Grecian imagination. According to these travellers, the island of Crete abounds even at the present day in extensive caverns, one of which, consisting principally of many long windings and narrow passages that can only be safely explored by means of a clue, exhibits a wonderful similarity in all essential particulars to the famous labyrinth of Dædalus. It is impossible, at this distant period, to pronounce with certainty on so difficult a question; but the substantial coincidences that exist between the ancient and modern labyrinths seem to leave little doubt as to their identity. (See *Geo. Dict.* art. "Crete.")

LA'BYRINTH. In Metallurgy, a series of troughs attached to a stamping mill, through which a current of water passes for the purpose of washing away the suspended pulverized ore, and subsequently depositing it at different distances, depending upon its state of comminution.

LA'BYRINTH. A term applied by anatomists to the internal parts of the ear, from the intricacy of their winding passages. See EAR.

LABYRI'NTHODON. (Gr. λαβυρινθος, and οδους, *a tooth.*) The name of an extinct genus of Reptiles, probably of the Batrachian order, characterised by teeth of a peculiarly complicated structure, the outer coat of enamel being inflected in complex wavy folds into the body of the tooth, and alternating with corresponding wavy plates of dentine, which give the appearance of a labyrinth to the transverse section of the tooth. The remains of the reptiles of this genus peculiarly characterise the Keuper formation of Germany, and the corresponding sandstones, as that of Warwick in England.

LAC. This substance flows from the *Ficus indica*, the *Khamnus jujuba*, and some other trees, in the form of a milky fluid, in consequence of punctures made upon their branches by a small insect, the *Coccus ficus*. The commercial varieties of lac are, *stick lac*, which is the substance in its natural state, investing the small twigs of the tree; *seed lac*, which is the same, broken off the twigs, and which when melted and formed into thin cakes constitutes *shell lac*. These varieties of lac have been examined by Mr. Hatchett (*Phil. Trans.*, 1804), with the following results: —

	Stick lac.	Seed lac.	Shell lac.
Resin - -	68·0	88·5	90·9
Colouring matter -	10·0	2·5	0·5
Wax - -	6·0	4·5	4·0
Gluten - -	5·5	2·0	2·8
Foreign bodies -	6·5		
Loss - - -	4·0	2·5	1·8
	100·0	100·0	100·0

The great consumption of lac is in the manufacture of dye stuffs, sealing wax, and of certain varnishes and *lacquers*.

LA'CCIC ACID. A peculiar acid separated from stick lac by Dr. John. It is yellow, crystallizable; and forms soluble salts with potassa, soda, and lime, and insoluble salts with the oxides of mercury and lead. It occasions no precipitate in solution of baryta or of oxide of silver.

LACCINE. A substance discovered in shell lac by Unverdorben. It remains after all the soluble matters in water, alcohol, and ether have been extracted. It is brittle, yellow, translucent; and soluble in caustic potash, and in sulphuric acid.

LAC DYE, LAC LAKE. These are two preparations of lac imported in small cubic cakes from the East Indies, and extensively used in the production of scarlet dye. They are said to be prepared by digesting lac in an alkaline solution, which produces a deep pink liquid, the colouring matter of which is thrown down in combination with alumina by the addition of a solution of alum.

LACE. (Lat. lacinia, *the hem of a garment.*) An ornamental fabric of linen or cotton thread, formerly made by hand (when it was called *pillow* or *bone* lace), but of late years produced by machinery, and generally termed *bobbin-net.*" This manufacture," says Dr. Ure, "may be said to surpass every other branch of human industry in the complex ingenuity of its machinery; one of Fisher's spotting frames being as much beyond the most curious chronometer in the multiplicity of mechanical device, as that is beyond a common roasting jack."

The costly and complicated machines by means of which bobbin-net is produced are termed *lace frames.* They are constantly undergoing improvements, and this beautiful branch of manufacture is apparently destined to become much more perfect than even at present.

A *rack of lace* is a certain number of meshes counted perpendicularly, and contains 240 meshes or holes; and such has already been the improvement in this manufacture, that the cost of labour in making a *rack*, which was twenty years ago three shillings and sixpence, is now reduced to one penny. Formerly the wholesale price of a 24-rack piece, five quarters broad, was 17*l.* sterling; the same is now sold for seven shillings. In the *Commercial Dictionary* will be found full statistical details of the value of the lace manufacture in this country, together with a learned and curious account of the origin and history of the fabric.

LACE'RNA. A long woollen military cloak, worn at first only by the Roman soldiers, but which increased so much in fashion that at the period of the triumvirate it became a favourite piece of dress with all the higher classes of Roman citizens, both civil and military, and remained so till the times of the emperors Valentinian and Theodosius, when the senators were prohibited from wearing them in the city. Martial speaks of lacernæ which cost 10,000 sesterces (80*l.*).

LACE'RTA. (Lat.) The *Lizard;* a constellation of the northern hemisphere, near Cepheus and Cassiopeia, formed by Hevelius.

LACE'RTIANS, or LACERTINE SAURIA. A name sometimes given to a primary division of the order *Sauria* of Cuvier, including all those species which differ from the Loricate or Crocodilian Sauria in having a direct communication between the ventricles of the heart, a double intromittent organ, a tongue bifurcate or emarginate at the tip, an ear-drum unprotected by an opercular fold, and a covering of scales sometimes bony, without osseous plates or scutæ.

LACE'RTIDÆ. (Lat. lacerta, *a lizard.*) A group of the order *Sauria*, forming the second family in the Cuvierian system, in which the characters are given as follows: — Tongue long, slender, extensible, and bifurcate at the extremity, as in the serpent tribe; ear-drum membranous, on a level with the surface of the head, or very slightly sunk; eyelids consisting of a production of the skin, with a longitudinal slit, closed by a sphincter, and a rudimental nictitating or third eyelid; body elongated; feet with five toes each; digits separate and unequal, particularly the hind ones, all armed with nails; scales on the belly and round the tail arranged in transverse and parallel bands. Cuvier subdivides the *Lacertidæ* into the two great genera *Monitor* and *Lacerta*, each of which have been again subdivided.

LA'CHES. (Fr. lache, *negligent.*) In Law, slackness or negligence. A term used to signify that degree of negligence which throws on the party committing it the evil consequences resulting to him from it.

LA'CHRYMAL. Relating to tears; as the *lachrymal glands*, by which they are secreted. They are placed in a depression of the frontal bone, above the external angle of the eye: the tears pass from them to the eye by the lachrymal ducts, which are six or eight in number.

LA'CHRYMATORY. A small vessel of glass or earthenware, which it was customary at Roman funerals to fill with the tears of the mourners, and deposit them with the ashes of the deceased in the sepulchre.

LACK. In Commerce, a word used in the East Indies, to denote the sum of 100,000 rupees, or 12,000*l.* sterling.

LACI'NULA. In Botany, a term given to the abruptly inflexed acumen of each of the petals of an umbelliferous flower.

LACO'NICUM. (Lat.) In Ancient Architecture, an apartment in the baths, which received its name from having been first used in Laconia.

LA'CONISM. A short and pointed saying; so termed from the celebrity which the Lacedæmonians enjoyed in antiquity for their brief and sententious mode of expressing themselves, produced by the severe discipline of their institutions, and the gravity which it engendered. When they became famous for this quality, they appear to have begun to aim at the exhibition of it in rather an affected manner, of which some curious instances are contained in Herodotus. None of the many Laconisms recorded in ancient history are more noble than the expression of the Spartan mother to her son, when presenting him with his buckler: ἢ ταν ἢ ἐπι ταν, — "either bring it back, or be brought home dead upon it." There is an essay by Puteanus, *De Laconismo*.

LA'CQUER. A yellow varnish, consisting of a solution of shell lac in alcohol, coloured by gamboge, saffron, annotto, or other yellow, orange, or red colouring matters. Lacquers are chiefly used for varnishing brass and some other metals, in order to give them a golden colour and preserve their lustre.

LACTA'RIUM. (Lat.) In Architecture, strictly a dairy house. In Ancient Architecture, it was a place in the Roman herb market, indicated by a column, called the Lactaria Columna, where foundlings were fed and nourished.

LA'CTEALS. (Lat. lac, *milk.*) The absorbents of the mesentery, which convey the milky fluid called *chyle* from the small intestines to the thoracic ducts.

LA'CTIC ACID. (Lat. lac.) The acid of sour milk. A similar acid is obtained from the fermented juice of the beet root. It appears to consist of 6 atoms of carbon, 5 of hydrogen, and 5 of oxygen, its equivalent being 81.

LACTO'METER. (Lat. lac, and metrum, *a measure.*) A term applied to a glass tube for ascertaining the proportion which the cream bears to the milk of any particular cow, or of the produce of a whole dairy. The tube is about half an inch in diameter, and a foot in height, with a graduated scale marked on the outside. It is filled with milk when newly drawn from the cow, and as it cools the cream rises to the surface, and the proportion which it bears to the milk is ascertained by counting the degrees opposite to each.

LACTU'CARIUM. The inspissated milky juice of the *Lactuca sativa*, or common garden lettuce. It possesses slight anodyne properties, and is sometimes used as a substitute for opium.

LACTU'CIC ACID. A peculiar acid, discovered by Pfaff in the juice of the *Lactuca virosa*. It bears some resemblance to oxalic acid; but differs from it in giving a green precipitate with the protosalts of iron, and a brown precipitate with sulphate of copper.

LACU'NA. (Lat.) In Botany, a term applied in describing lichens, to denote one of the small hollows or

pits on the upper surface of the thallus. Also a name given occasionally to the internal organ, commonly called an air-cell, lying in the midst of the cellular tissue of plants.

LACU'NAR. (Lat.) In Architecture, the ceiling or under surface of the member of an order. Also the under side of the larmier or corona of a cornice. The under side also of that part of the architrave between the capitals of columns. The ceiling of any part in architecture only receives the name of lacunar when it consists of compartments sunk or hollowed without spaces or bands between the panels: if it is with bands, it is called *laquear*.

LACUNO'SE. (Lat. lacuna. *a break.*) In Zoology, when a surface has a few scattered, irregular, broadish, but shallow excavations.

LACU'STRINE. (Lat. lacus, *a lake.*) Belonging to a lake. The term *lacustrine deposit* is applied by geologists to certain fresh-water formations which occur in the newer rocks. *See* GEOLOGY.

LADDER. The sea term for the staircases between the decks. Ladders are also made of rope.

LA'DY. A title said to be compounded of two Saxon words, and to signify the giver or distributor of bread; *i. e.* the mistress of a family. It properly belongs to the daughters of all peers above the rank of a viscount; and is extended, by courtesy, to the wives of knights of every degree.

LA'DY DAY. In the Calendar, the 25th of March, being the annunciation of the Holy Virgin. It is one of the immoveable festivals of the church, having relation to Christmas, or the day of the nativity of Christ, which it precedes by nine months.

LÆMODI'PODS, *Læmodipoda.* (Gr. λαιμος, *throat*, πους, *foot.*) The name of an order of Crustaceans, in which the head is confluent with the first segment of the thorax, and supports the four anterior feet. The *Læmodipods* are the only Malacostracans with sessile eyes, and in which the posterior extremity of the body exhibits no distinct branchiæ. The females carry their ova beneath the second and third segments of the body in a pouch formed of approximated scales. All the species are marine.

LA'GOMYS. (Gr. λαγως, *a hare;* μυς, *a mouse.*) The generic name of certain Rodents, called "rat-hares," now peculiar to Siberia. They differ from the hares proper in having moderate-sized ears, legs nearly equal, clavicles nearly perfect, and no tail. The fossil bones of a species of *Lagomys* have been discovered in the osseous breccia of Corsica.

LAGOO'N. (Lat. lacuna, *a morass.*) The name given particularly to those creeks extending along the coast of the Adriatic, and which are formed by water running up in the land. In some places they are deep; but generally they are so shallow as to emit noxious exhalations. They contain many islands; on sixty of which the city of Venice is built. Towards the sea these islets are secured by dams, either natural or artificial.

LAGO'PUS. (Gr. λαγως, *a hare;* πους, *a foot.*) The generic name of those birds of the grouse tribe which have a round or square tail, and whose toes are feathered as well as the legs. *See* PTARMIGAN.

LAGO'STOMA. (Gr. λαγως, and στομα, *the mouth.*) The harelip.

LA'GOTHRIX. (Gr. λαγως; θριξ, *a hair.*) A genus of South American or Platyrrhine monkeys, characterized by their round head, a thumb on the anterior hand, and the tail partly naked. The grison, or silver-haired monkey, is a species of this genus.

LAGRIMO'SO. (Ital.) In Music, a direction to the performer, when appended to a piece of music, denoting that it is to be performed in a weeping, plaintive manner.

LAIRD. A Scottish term, applied, as Libb observes, to "a landed gentleman under the degree of a knight;" but regarded by many philologists as originally equivalent to *lord* (quod vide). Anciently the title of laird was given only to those proprietors who held immediately of the crown; and this distinction is still preserved in the Highlands. The designation *tiern*, corresponding to laird and rendered by it, is given to no one whose property is not worth two or three hundred per annum, while it is withheld from another whose rental extends to as many thousands; because the former acknowledges no superior under the king, while the latter does.

LA'ITY. (Gr. λαος, *people.*) The great body of the faithful, as opposed to those who are set apart for the ministration of the services and sacraments — the clergy. This distinction is plainly observed in the writers of the third century — Origen, Cyprian, and Tertullian; and is generally supposed to have prevailed from the first foundation of Christianity. The word laity is properly a general name for the people: in the writings of the Fathers βιωτικοὶ, seculars, ἰδιῶται, private men, and λαικοὶ, laymen, are used indifferently to express this class.

LAKE. (Lat. lacus.) In Geography, a collection of water surrounded by land. Lakes are divided into four distinct classes: — 1. Those which have no outlet, and receive no running water. 2. Those which have an outlet, but receive no superficial running water, and are consequently fed by springs. 3. Those (by far the most numerous class) which both receive and discharge streams of water. 4. Those which receive streams of water, and which have no visible outlet or communication with the sea. The Caspian Sea, which receives the Wolga and several other large rivers, and Lake Aral, which receives the Amoo, belong to this class. It is a remarkable fact, that all lakes of this class are salt. Some lakes present the curious phenomena of disappearing and reappearing periodically, without regard to the rainy season. Lake Chirtunitz in Illyria is of this description. Some of them, as Loch Lomond in Scotland, and Lake Wetter in Sweden, experience violent agitations during severe weather. This may be supposed to proceed from an escape of subterraneous gases, or winds blown into some cavern with which they communicate; though a coincidence of dates leaves ground to suppose that the phenomenon was connected with earthquakes in distant countries.

LAKE. A compound of aluminous earth with the red colouring matter of certain animal and vegetable substances; thus we have cochineal and lac lakes, madder lake, &c. Sometimes the term *lake* is indiscriminately applied to all compounds of alumina and colouring matter.

LALLA'TION. The imperfect pronunciation of the letter *r*, which is made to sound like *l;* hence also the term *lambdacismus*. The imperfect pronunciation of the letter *r* is peculiar to the Chinese.

LA'MA. (Mother or pastor of souls.) Among the Mongols a title given to priests in general; among the Calmucks to the higher classes of priests only. The Dalai-Lama (*i. e.* Great Lama) is honoured as the representative of divinity, or rather as a real divinity dwelling on the earth, by various tribes of Tartaric descent. This personage resides at Lassa in Thibet, and pilgrimages are made to his residence by the inhabitants of many distant regions of Tartary. He is now chiefly dependent, in a political sense, on the Chinese empire. When the actual Dalai-Lama dies, his spirit is supposed to seek another body in which to be born again; and the new Dalai-Lama can only be discovered by a certain favoured class among the priests. The worshippers of the Dalai-Lama also pay peculiar reverence to two other subordinate Lamas (Teeshoo and Taranaut Lama). They are distinguished by the title of *Yellow Caps:* the *Red Caps*, another sect in Tartary, are under three other Lamas, styled the three *Shamonars*.

LAMA, LLAMA, or GLAMA. The name of a species of the camel tribe peculiar to South America. *See* AUCHENIA.

LAMA'NTIN. The name given by French naturalists to the manatee or sea cow. *See* MANATUS.

LAMBDOI'DAL SUTURE. The union of the parietal with the occipital bones; shaped something like the Greek letter Λ, or *lambda*.

LAME'LLA. In Botany, a term applied by some writers to the foliaceous erect scales appended to the corolla of many plants, as in *silene*. Also used in describing fungi, to denote the gills forming the hymenium of an agaric.

LAMELLIBRA'NCHIATES, *Lamellibranchiata.* (Lat. lamella, *a thin plate;* branchiæ, *gills.*) An order of Acephalous Mollusks, comprehending those which have the gills in the form of large semicircular layers disposed symmetrically, two on each side.

LAME'LLICORNS. (Lat. lamella, *a plate;* cornu, *a horn.*) The sixth and last section of Pentamerous Coleoptera of the system of Latreille, in which the antennæ are inserted into a deep fossula under the lateral margin of the head: they are always short, usually consist of nine or ten joints, and are always terminated in a club, usually composed of the three last, which are lamellar. Sometimes flabelliform, or disposed like the leaves of a book, opening and closing in a similar way; sometimes concentrically contorted and fitting into each other, the first or inferior then being semi-infundibuliform and receiving the others; and sometimes arranged perpendicular to the axis, and forming a sort of comb.

The body is generally ovoid or oval, and thick. The exterior side of the two anterior tibiæ is dentated; and the joints of the tarsi, with the exception of those of some males, are entire, and without brush or pellet beneath.

The anterior extremity of the head most commonly projects, or is dilated in the manner of an epistome. The mentum is usually large, covers the labrum, or is incorporated with it, and bears the palpi. The mandibles of several are membranous, a character observed in no other Coleopterous insects. The males frequently differ from the females, either by prominences on the thorax or head in the form of horns or tubercles, or by the largeness of their mandibles.

This family is very numerous; and with respect to the size of the body, and the variety of forms exhibited in the head and thorax, is one of the most beautiful of the order; and frequently also as regards the splendour of the metallic colours which ornament those species feeding on living vegetables. The other species, however, feed-

ing on decomposed vegetable matter, are usually of one black or brown hue. Some of the Coprophagi, however, do not yield even in this respect to the former. They are all furnished with wings, and their gait is heavy.

The body of the larvæ is long, almost semicylindrical, soft, frequently rugose, whitish, and divided into twelve annuli, with six squamous feet: the head is squamous, and armed with stout mandibles. Each side of the body is furnished with nine stigmata or breathing pores. Its posterior extremity is thicker, rounded, and almost always doubled under it; so that the back being arcuated or convex, the animal cannot extend itself in a straight line, crawls badly on a level surface, and falls backwards or on its side every instant.

Some of them require three or four years to become pupæ: they construct in their place of residence an ovoid shell, or one resembling an elongated ball, composed of earth or the remains of substances they have gnawed, the particles of which are cemented by a glutinous matter produced from their body. Their aliment consists of the dung of various animals, mould, and the roots of vegetables (frequently such as are necessary to man), of which they sometimes destroy immense quantities, to the great loss of the cultivator of the soil.

LAMELLIRO'STRALS, *Lamellirostres*. (Lat. lamella, *a thin plate;* rostrum, *a beak.*) A tribe of swimming birds, the fourth in the system of Cuvier, comprehending those in which the margin of the beaks are furnished with numerous lamellæ or dental plates, arranged in a regular series, as in the swan, goose, and duck. The birds comprised in this family pass most of their time in the fresh waters. Some come on shore to graze; others feed on aquatic plants, insects, vermes, or small fish, and reptiles, which their long neck enables them to reach or seize with facility. Some of the species dive in quest of their prey, and can remain a considerable time under water. All the Lamellirosters of Cuvier were comprised in the great genus *Anas* of Linnæus.

LA'MIA. (Gr. Λαμια.) An imaginary being, concerning which many superstitious notions were prevalent among the Greeks and Romans; sometimes represented as a species of monstrous animal, sometimes as a spectre or vampire. The Lamiæ of Pliny are animals, with the face and head of a woman and tail of a serpent, inhabiting the deserts of Africa. According to mythologists, the first Lamia was a daughter of Neptune, a malevolent goddess, who seizes and devours new-born infants in their cradles: whence Horace's caution to tragic writers against indulging in the description of unnatural horrors: —

Nec pransæ Lamiæ vivum puerum extrahat alvo.

In the well-known story of Machates and Philemon from which Goethe has borrowed his magnificent ballad of the *Bride of Corinth*), a young man is represented as marrying a Lamia, or Empusa, who sucks his blood at night. A similar tale occurs in the *Life of Apollonius of Tyana* by Philostratus. The Christian superstition of incubi, and the oriental belief in vampires, seem to bear marks of the same origin.

LAMI'DÆ. (Lat. lamia, the name of an imaginary animal in Pliny.) The subdivision or family of *Laminæ*, in which the sides of the thorax are either smooth and rounded, or tuberculate, rugous, or spiny, but not furnished with moveable tubercles or spines.

LAMI'NÆ. (Lat. lamia.) A tribe of Longicorn beetles, distinguished, according to Latreille, by their vertical head; filiform palpi, whose terminal joint is more or less ovoid and tapers to a point; maxillæ with the outer lobe slightly narrowed at the end; antennæ frequently setaceous and simple; and thorax, exclusive of the lateral spines or tubercles, nearly equal throughout. Some species are apterous, a modification which occurs in no other tribe of Longicorn beetles.

LA'MINARITES. A term applied by Brogniart to a species of fossil fucies found in the secondary strata of Aix, near La Rochelle.

LA'MMAS DAY. In the Calendar, the 1st of August. Dr. Johnson supposes this term to be a corruption of *Lattermath*, which signifies a second mowing of grass. Others derive it from a custom which once prevailed in some parts of England, of bringing a lamb alive on this day into the church at *high mass*. Others again derive it from a Saxon term signifying *loaf-mass*, so named as a feast of thanksgiving for the first fruits of the corn.

LAMP. (Gr. λαμπας.) The general term for the well-known contrivances used in producing artificial light from the combustion of liquid or other inflammable bodies. The peculiar applicability of oil to the production of artificial light, which could not fail to be discovered at a very early period, rendered the use of lamps universal among the nations of antiquity. The Egyptians, the Hebrews, Greeks, and Romans, vied with each other in the construction of these instruments; and the specimens of some that have been transmitted to our times display much taste and elegance of external design. It would seem, however, that the ancients had confined themselves merely to the external embellishment of the lamp; for it is a singular circumstance, that notwithstanding the simplicity of the invention, and its obvious capability of improvement, it is only within the last sixty years that any material improvement has been effected in its original construction. To give any thing like a complete view of the principles and structure of the numerous lamps of which the present age has witnessed the invention would be quite impracticable without a multiplicity of illustrative diagrams, which would be foreign to the purpose of this work; but a brief notice of the principle on which the action of every lamp, both simple and complicated, depends, and of some of the most celebrated improvements in their structure, may not be considered out of place.

The most simple lamp consists in a vessel of any shape filled with oil or other inflammable liquid, and having a short depression or spout on one side, in which lies a wick composed of any fibrous substance, and capable of imbibing the oil by its capillary attraction. The oil thus raised and diffused through the wick, when ignited, admits of being heated to such a degree of temperature as is capable of volatilizing the oil, the vapour of which, in a state of combustion, constitutes the flame of the lamp. The wick of a lamp serves only for the purpose of raising up the oil by capillary attraction, and thus giving a constant and adequate supply to the flame. It furnishes no part of the light by the combustion of its own substance; for the quantity consumed is too small to merit attention, and it is usually coated over with a broad deposit of carbonaceous matter, which cannot burn for want of the access of air, from which it is kept by the flame. To render the air accessible to every part of the flame in order to ensure the most perfect combustion of the oil, is one of the most essential objects in the modern improvement of lamps; and hence the texture, materials, and dimensions of the wick are matters of much importance. If, on the one hand, the wick be large, a great deal of carbon vapour remains unburnt in the interior of the flame, and breaks out in the form of smoke, producing a most disagreeable smell; and if, on the other hand, the wick be too small, though the unconsumed carbon will naturally be less, and the flame consequently clearer than those of the larger wick, it will yield but very little light, as the light diminishes with the superficies of the flame. The inconvenience of a thick wick had been long observed, and attempts were often made to remove it; in some instances by substituting two or more small wicks for one large one, and in others by making the wick flat instead of cylindrical. These experiments, though limited in their operation, were no doubt beneficial; and in houses where economy more than elegance was studied, they procured for the lamp a more extended use than it previously enjoyed. Still, however, the smoke and disagreeable smell arising from the burning of oil in common lamps, and the unsightly appearance of the whole process, had long banished the lamp from the apartments of the wealthy; and it was not till the year 1780, when M. Argand invented the well-known lamp which bears his name, that the instrument came into general use. This invention embraces so many improvements upon the common lamp, and has become so general throughout Europe, that it may be justly regarded as one of the greatest discoveries of the age. As a substitute even for the best wax candles, it combines the advantage of economy and convenience, with much greater brilliance; while even as a means of producing heat it is found to be of most essential service in chemical operations. The great principle on which the superiority of this lamp depends is the admission of a quantity of air into the centre of the flame. This Argand accomplished by making the wick of a circular form, instead of a solid cylinder as before; by which means a current of air rushes through the hollow cylinder while the wick is burning, thus admitting air into the centre of the flame. Improving upon this invention, which was found perfectly to succeed, he added a glass cylinder or chimney, open at bottom, to surround the flame at a short distance; by which another current of air is made to pass upwards on the exterior part of the flame, and between it and the glass. Thus every part of the thin circular flame is between two currents of air, which supply the combustion with such a quantity of oxygen as to create a heat sufficient to convert into a brilliant flame the smoke which escapes from an ordinary lamp.

Such is a brief account of the leading principles of Argand's invention. Various improvements have since been made on the original by the Sinumbra, the French, the Iris lamp (now in general use as a table lamp), and a variety of others, which it would be superfluous to enumerate; all of which, however, may be regarded as improvements more of *detail* than *principle*. Indeed, the great merit of Argand's invention consists in the facility with which it can be ingrafted on lamps of every variety of form and structure; while not all the beauty of design and execution witnessed in the endless diversity of the lamps at present in general use, would be sufficient

to procure for them any considerable notice, if they were destitute of the Argand principle. This facility of general application has recently been exemplified in an ingenious invention, by which lamps on the Argand principle have been made to burn the common fish oil, instead of spermaceti, which had hitherto been indispensable. This improvement, which is so desirable in an economical point of view, consists chiefly in an extension of Argand's original principle; viz. in supplying the flame with a greater quantity of oxygen than had hitherto been effected. This is accomplished by means of apertures in the sides of the lamp, and a cap with a *deflector*; but in applying this improvement to lamps on Argand's principle, a larger and coarser kind of wick must be employed, and the tubes with which the burners and the wick are supplied with oil must also be enlarged. Lamps constructed on this principle are designated *solar lamps*. The best account of lamps is to be found in *Peclet, Traité de l'Eclairage*, Paris, 1827; and in *Krünitz's Encyclop.*, art. "Lampe." See also the *Haus Lexicon*.

LA'MPADEPHO'RIA. (Gr. λαμπαδηφορία, *a carrying of torches*.) A torch race, which it was customary to exhibit at certain sacred festivals at Athens. The performers were three young men, to one of whom, chosen by lot, was given a lighted torch, which he was to carry to the goal unextinguished; or if he failed, to deliver it to the second; who, if he failed also, gave it to the third: whence a metaphor is sometimes derived by ancient writers, to be applied to persons who anxiously wait for the deaths of others. If the runners slackened their pace, they were driven on by the blows of the spectators. This ancient usage is beautifully applied by Lucretius to the succession of human generations: —

Et, quasi cursores, vitaï lampada tradunt.

LAMPBLACK. Finely divided charcoal. It is the soot obtained by the imperfect combustion of resin of turpentine; this is burned in chambers hung with old sacking, upon which the smoke collects, and is from time to time scraped off. It contains about 20 per cent. of peculiar resinous products, water, and saline matter.

LA'MPIC ACID. A term given by Mr. Daniell to the acid produced by the slow combustion of the vapour of alcohol and ether in the lamp without flame: he has since ascertained that it is acetic acid modified by the presence of a peculiar hydrocarbon.

LAMPOO'N. *See* SATIRE.

LAMP, SAFETY. *See* SAFETY LAMP.

LAMPY'RIDÆ, *Glow-worms*. (Gr. λαμπυρις, *a glow-worm*.) A family of soft-skinned Serricorn beetles, of the tribe *Lampyrinæ* (which see), characterized by antennæ closely approximated at their base; head concealed beneath the thorax, or produced in the form of a snout; eyes of the males large and globular; mouth small. In one division the abdomen of the female is luminous; and the male, which is destined to be attracted by this luminosity, has his head almost entirely occupied by his largely developed eyes, and it is not produced in the form of a snout. The luminous property of the glow-worm is confined to the two or three terminal segments of the flattened abdomen, which differ in colour from the rest, and are usually yellowish or whitish; this character is peculiar to the true glow-worms, and announces their phosphorescence. The light diffused by the glow-worm is of a lambent, electric, greenish colour: the insect can vary or suspend its luminosity at will. The light-emitting segments preserve their peculiar property for some time after being separated from the rest of the body, and manifest it even *in vacuo*, or when immersed in gases which are not supporters of combustion.

In a second division of *Lampyridæ* the females are not luminous, but are provided with wings; the head is exposed, and is mostly produced in the shape of a snout; the thorax is widened posteriorly, with pointed lateral angles. The elytra, in several, expand posteriorly, where they are sometimes strongly dilated or rounded, especially in the females. To this group belong the genera *Lycus*, *Dictyoptera*, and *Omalisus*.

LAMPY'RINÆ. (Gr. λαμπυρις, *a glow-worm*.) A Linnæan genus of Coleopterous insects, which constitutes the type of the present tribe of the soft-skinned or Malacodermous Serricorns in the system of Latreille. This tribe is characterized by the enlarged termination of the palpi, or at least of the maxillary palpi; by their soft, straight, depressed, or but slightly convex body; and by the thorax, sometimes semicircular, at others nearly square or trapezoidal, and projecting over the head, which it either wholly or partially covers. The mandibles are usually small, and terminate in a slender, arcuated, very acute point, which is generally entire. The penultimate joint of the tarsi is always bilobate, and the terminal claws have neither dentations nor appendages.

The females of some of the Lampyrine tribe are apterous, or have but very short elytra, and are luminous. All the Lampyrines, when seized, press their feet and antennæ against their body, and remain as motionless as if they were dead. *See* LAMPYRIDÆ.

LA'NATE. (Lat. lana, *wool*.) In Zoology, when a part is covered with fine, very long, flexible, and rather curling hair, like wool.

LANCASTER, CHANCELLOR OF THE DUCHY OF. The officer before whom, or his deputy, the court of the Duchy-Chamber of Lancaster is held: which is a court having special equitable jurisdiction as to lands holden of the duchy. The office has long been a sinecure, and is one of the most valuable at the disposal of the ministry of the day; the salary is 4000*l.* per annum.

LANCE. (Fr.) A weapon consisting of a long shaft with a sharp point, much used by the nations of antiquity, and also by the moderns before the invention of gunpowder. The Macedonian phalanx and the Roman infantry, as well as the most barbarous nations, all considered the lance as one of the most effective weapons; and even at the present day it is still considered of great value, though it is now almost universally borne by cavalry. Almost all the armies of Europe have now regiments of *lancers*, so called from the lance being the chief offensive weapon with which they are armed. The lances in use among the European cavalry have a shaft of ash or beech wood, eight, twelve, or in some cases even sixteen feet long, with a steel point eight or ten inches in length, adorned by a small flag, the waving of which is said to frighten the enemy's horses. The ancient lancea was a general term for missile weapons or javelins: the pilum is termed lancea in Lucan: —

Cujus torta manu commisit lancea bellum. (Lib. vii.)

For a detailed description of the lances of knights in the middle ages, see *Mem. de l'Ac. des Inscr.* vol. xx. From its being the common knightly weapon, the force of the mounted gendarmerie on its first institution in the 15th century was usually numbered by "lances," each "lance" having four or five attendants. The lance has become again a favourite cavalry weapon of late years, owing to the exploits of Napoleon's Polish lancers and the Cossacks.

LA'NCEOLATE. (Lat. lancea, *a lance*.) In Zoology, an animal or a part is so called when it is oblong and gradually tapering towards each extremity.

LAND (Germ.), in its widest acceptation is used to denote the solid matter of which the globe is composed, in contradistinction to the liquid matter, or water; but in its most restricted signification it is confined to *arable ground*. The latter is the legal meaning of the term; and in this sense it is used in all original writs, and in all correct and formal pleadings.

LA'NDAMMAN, in Switzerland, the president of the diet of the Helvetic republic. The highest magistrate in ten of the cantons also bears the title of landamman; in the others he is designated by various appellations.

LA'NDAU. The name given to a peculiar kind of carriage, which opens and closes at the top; so called from Landau in Germany, where they were originally made.

LA'NDFALL. The first land seen after a voyage is so called. A *good* landfall is when the land is seen as expected.

LA'NDGRAVE. A title taken by some German counts in the twelfth century, who wished to distinguish themselves from the inferior counts under their jurisdiction; and thus assumed the designation of land-graf, or count of the whole country. This was the origin of the landgraves of Thuringia, of Lower and Higner Alsace, the only three who were princes of the empire.

LAND-LOCKED. A term applied to a harbour or piece of water which is so environed by land on all sides as to exclude the prospect of the sea, unless over some intervening land. If a ship is at anchor in such a place, she is said to ride land-locked, and is therefore considered to be safe from the violence of winds and tides.

LA'NDMARK signifies, in a general sense, any thing by which the boundary of a property is defined. In ancient times the correct division of lands was an object of great importance; and various means were adopted to give distinctness and permanency to the boundaries of every man's property. Stones and hillocks were the most usual landmarks. The importance of this subject, among the Israelites particularly, may be judged of from the denunciation of Moses: "Cursed be he that removeth his neighbour's landmark." In naval language, *landmark* is applied to any conspicuous object which serves as a guide in entering a harbour, or avoiding a danger.

LANDREEVE. A subordinate officer on an extensive estate, who acts as an assistant to the land steward.

LANDSCAPE. The scenery presented to the eye in the country; as also, in its more common acceptation, a picture representing such scenery. A landscape in the latter sense may, however, become allegorical and historical, in the meaning applied by artists to those terms. The chief study of the landscape painter is the vegetable world, air, water, rocks, and buildings. To these he may impart an ideal beauty, and thus elevate his art

above mere topographical painting; which may be applied to his work, if he merely copies without refinement what is presented to his eye.

LANDSCAPE GARDENING. The art of laying out grounds so as to produce the effect of natural landscape. Its principles are the same as those upon which the landscape painter proceeds in composing a picture; and though it is an art of which, like many others, every body thinks he is a judge, it requires, to be properly practised, powers of a much higher order than fall to the lot of most men. Mr. Brown, commonly called Capability Brown, was the first who practised the art in this country so as to render himself worthy the name of an artist. To lay down the principles of the art would be quite impossible in this article; but this general observation contains the sum of them, — let selected and beautiful nature be constantly your model, and success must follow.

LANDSLIP. A portion of land that has slid down in consequence of disturbance by an earthquake, or from being undermined by the action of water.

LAND SPRINGS. Land springs are sources of water which only come into action after heavy rains; while constant springs, which derive their supplies from a more abundant source, flow throughout the year. All springs owe their origin to rains. In the case of land springs, the water, when it sinks through the surface, is speedily interrupted by a retentive stratum, and there accumulating soon bursts out in a spring, which ceases to flow a short period after the cause which gave it birth has ceased to operate; but the water which supplies constant springs sinks deeper into the earth, and accumulates in rocky or gravelly strata, which become saturated with the fluid.

LAND STEWARD. A person who has the care of a landed estate, and whose duties vary in different countries according to the mode in which landed property is managed. In England, where the landlord very commonly undertakes to keep the buildings and fences of his tenants in repair, the duties of the land steward are constant and multifarious; while in Scotland, where the buildings and fences are kept in repair by the tenant, the duties of the steward are limited to receiving the rents, and seeing that the covenants of the leases are duly fulfilled. In many parts of the Continent, and particularly in Italy, where the landlord is a partner with his tenant, and shares the produce with him, the duties of the land steward, or *fattore*, as he is there called, are much more onerous than in Britain. It is generally considered, both by British and Continental writers on agriculture, that one principal cause of the retardation of this art has been the employment of lawyers as land stewards; and the truth of this can hardly be denied, more especially in those countries where the tenant is bound down by his lease to particular modes of cropping, or where there is a discretionary power as to cropping on the part of the steward. The objection to lawyers as stewards is founded on their general habits of acting from precedent rather than from principle; and hence such a habit, exercised in the case of an art that is calculated to be so rapidly progressive as agriculture, must materially impede its advancement. At the same time the convenience to a landed proprietor of having a land steward who possesses legal knowledge is so great, as generally to overpower the objections that are made against them by farmers and agricultural writers.

LA'NDWAITER. An officer of the customs, whose duty it is upon landing any merchandise to taste, weigh, measure, or otherwise examine the various articles, &c., and to take an account of the same.

LA'NDWEHR. (Germ. *land-guard*.) The militia of Prussia and Austria are so called. *See* MILITIA.

LA'NGREL. A particular kind of shot formed of bolts, nails, and other pieces of iron, tied together, and forming a sort of cylinder which corresponds with the bore of the cannon from which it is discharged. It is used chiefly to destroy the masts and rigging of the enemy's ships.

LANGUAGE (Lat. lingua, *tongue*), has been defined "the expression of our ideas and their various relations by certain articulate sounds, which are used as the signs of those ideas and relations."

Whether language was originally given to man by his Creator, or is the fruit of human invention, is a subject of dispute, on which philosophy is scarcely capable of arriving at satisfactory conclusions. Among those writers who have maintained the latter thesis, three (*Lord Monboddo on the Origin and Progress of Language; Adam Smith's Considerations on the Formation of Languages;* and *Stewart's Philosophy of the Human Mind*, part 3.) are particularly deserving of attention. The first of these, in his ingenious speculation on the subject, mentions four ways in which he conceives that ideas could have been communicated before the invention of speech: viz., 1. Inarticulate cries, expressive of sentiment sand passions; 2. Gestures, and the expression of countenance; 3. Imitative sounds, expressive of audible things; and, 4. Painting, by which visible sounds are represented. And he appears to consider language to have been produced by gradual development out of the *first* of these.

Many, whether satisfied with Lord Monboddo's speculations or not, are ready to condemn the supernatural theory as "unphilosophical." But our views on this subject must materially depend on those which we may take of the kindred speculations respecting the origin of civilization. If we are led to the conclusion — once commonly adopted, with little inquiry, by philosophical writers — that the progress of man from the lowest state of barbarism to refinement has been gradual in all societies, we shall probably also believe that the formation of language accompanied this development in its course. But if we are more forcibly impressed with the strength of the *historical* difficulties which oppose this theory; that all our research only reveals to us the story of one family of civilized men (in the proper sense of that word) succeeding another; that the more barbarous races appear to have lost civilization, — to have fallen back from some better condition, instead of being at the lowest or commencing step (a notion strongly entertained by the gifted historian Niebuhr, among many others); and that the languages of some of the most savage races (such as several of the American Indians), instead of partaking in their want of refinement in other respects, are remarkable for the number and delicacy of their inflexions; — we shall probably arrive at the conclusion, that the more likely speculation is that which coincides best with the faint indications afforded by the inspired writings, and points out Revelation as the source both of knowledge and of the primary laws of human society.

Considering the phenomenon of language as it now presents itself, the most interesting philosophical questions to which it gives rise are those which concern the connection and relative antiquity of existing languages, and their comparative utility and beauty as modes of communicating ideas. The first lead the mind to consider the history of language; the latter the principles of its structure.

The former of these subjects is one of those which may be most emphatically pronounced peculiar to modern research. The affinity of the great family of European and Western Asiatic languages, those with which we are the most familiar, was scarcely studied with serious attention before the time of Adelung (whose great work, *Mithridates*, appeared, we believe, in 1804). The affinities of the Semitic and other oriental tongues had been, perhaps, earlier investigated; but their elucidation remains nevertheless still more imperfect at the present day. On a topic now pursued with great interest, especially by the learned men of Germany and Britain, we must content ourselves with indicating a few simple rules for the guidance of the student.

The importance of the coincidence of single words, as a proof of the connection of languages, is rather under than over estimated in common opinion. The late Dr. Young, whose researches into this question are of such high value, calculated that nothing could be inferred, as to the relation of two languages, from their agreement in *one* word; that the odds are only three to two against their casual agreement in *two;* but that they rise so rapidly that there are nearly 100,000 chances to one against their casual agreement in *eight*.

But, again, nothing could be inferred as to the relationship of languages from their agreement in particular words, if the nations which spoke them were neighbours, and the words such as the one might easily borrow from the other by mutual intercourse. The Latin word and the low German word for wine are the same; vinum, wyn, pronounced *veen*. But the Germans learnt the use of the thing from the Romans; and along with it they doubtless borrowed the name. No conclusion could therefore be drawn from this example, as to the connection between German and Latin. The Greek name for a lion, *lis*, is nearly the same with that used in a very different family of languages, the Semitic (Hebrew, laist; Arabic, laith). But the animal itself, although at one time occasionally found in Greece, was probably a wanderer from Asia; and the fact of its name being common to both tongues proves therefore nothing as to their relationship.

In examining the connection of languages by their agreement in words, two things are to be considered: the root, and the inflexions. The root is arrived at by striking off the inflective part of the word. Thus the termination *us* (properly *os* or *o*) is the inflective part, in the nominative, of a numerous order of masculine nouns in Latin as well as Greek. The root of "equus" is equ, or ec; the root of "albus" (white), alb. It is in these roots that we are first to look for the connection of languages; and in examining them it is necessary to acquire a knowledge of one of the most important and most difficult to ascertain among the primary facts relating to languages, the ordinary substitution of letters, especially consonants, in different cognate languages of the same family. With reference to the great class of languages already alluded to, commonly called the "Indo-European," these substitutions have been only of late classified, and that as yet

imperfectly. Thus it has been found that the Greek aspirate is often represented in Latin by *s*, ἑξ, ἑπτα, *sex*, *septem*; that the Greek π is frequently represented in the Teutonic tongues by *f*, πους, πατηρ, *foot*, *father*; that the Greek and Latin *d* is often *z* in German, *dens*, *digitus*, *decem*—*zahn*, *zehe*, *zehen*. A good list of the most common among these transformations will be found in the *Penny Cyclopædia*, art. "Language," taken from *Potts' Etymologische Forschungen*.

Correspondence in inflexions is a still closer sign of relationship. That peculiar class of Greek verbs commonly called in our grammars "verbs in *mi*" has a corresponding class in the Sanskrit, Zend, and some Sclavonic tongues.

	Greek.	Sanskrit.	Lithuanian.
I stand,	ἱστημι	Tisthâmi.	Stowmi.
Thou standest,	ἱστης.	Tisthâsi.	Stowi.
He stands,	ἱστησι.	Tisthâti.	Stow.
I give,	διδωμι.	Dadâmi.	Dudmi.
Thou givest,	διδως.	Dadâsi.	Dusi.
He gives,	διδωσι.	Dadâto.	Dusti.

In other cognate languages this mode of conjugation is either lost or much altered. Here, therefore, is an indication (not, of course, a conclusive one) of a nearer connection between these than others of the same family; Celtic and Latin, for instance.

The connection between languages being established, the mind is next led to consider their derivation one from another. And here historical assistance soon fails us. We say that Spanish and Italian are derived from Latin, because we know the fact historically; but at the earliest period of which we have any authentic account we find several independent nations using different, but strongly resembling varieties of speech, of whose historical connection we know nothing. We know little, for example, on the question in what consisted the relationship between the Latins and the Greeks; and nothing whatever as to the connection of either with the Celts or the Sclavonians. And hence it is easy to perceive the absurdity of the fashion, of which we still constantly meet with examples in dictionaries and works of reference, of speaking of words in cognate languages as "derived" from one another; for example, a Latin word as "derived" from the Greek, an English as "derived" from the German. The Romans undoubtedly, in later ages, borrowed a few words from the richer vocabulary of Greece; *e. g. historia, poema;* and the English have borrowed a very few from the Germans. But Greek and Latin, Anglo-Saxon and German, are respectively only varieties, derived alike from some ancient original which our inquiries are unable to reach.

The distinction between a separate language and a dialect is very arbitrary. We speak of Spanish and Portuguese, Swedish and Danish, as distinct languages; yet they resemble each other quite as nearly as some varieties of French, perhaps of Italian. The name seems appropriated, in ordinary usage, to every variety of speech which is in national use for purposes of government and literature.

The relative antiquity of languages is a subject involved in obscurity, and on which our conclusions are little better than conjectural. The theory that all languages are derived from a common original is difficult to be maintained; and yet there is no doubt that the tendency of modern research is, by accurate classification, to reduce the number of original tongues from which those in actual use are derivative varieties.

The following table of languages, divided into classes or groups, is given by Dr. Young, in the art. "Language," in the *Encyclopædia Britannica*.

1. Monosyllabic class: Chinese. Siamese. Avanese. Tibetan.

2. Indo-European class: Sanskrit. Zend (Median). Semitic (Arabian, Syriac, Hebrew, &c.) Lycian. Phrygian. Greek. Germanic. Celtic. Etruscan. Latin. Cantabrian. Sclavic.

3. Tartaric class.
4. African class.
5. American class.

This classification, however, is rather geographical than ethnographical, and in some respects apt to mislead. For example, those great families of languages, the Sanskrit, Greek, Latin, and Germanic, are all nearly connected with one another. The Celtic and Sclavic belong to the same division; while the Semitic languages form a very peculiar group apart, and should be excepted from the Indo-European class.

Languages have also been classed in the following manner:—

1. Languages composed of monosyllabic roots without any form of grammar. These have no inflexions, and variety of meaning is only shown by the position of words in a sentence. To this order belong the languages which Dr. Young terms monosyllabic.

2. Languages composed of monosyllabic roots with a great abundance of grammatical forms. Of these the great Indo-European family are an example.

3. Languages whose verbal roots consist, in their present form, of two syllables, and require three consonants to express their fundamental meaning. This division appears to comprehend the Semitic languages only, as far as is at present ascertained.

The comparative perfection of a language, as an instrument for the communication of thought, depends mainly on its copiousness. In order to estimate this, it must be borne in mind that the classes of words employed in a language are all reducible into two, which have been termed by some *notional* and *relational*. The former express distinct ideas or notions; the latter serve to display the relation, connection, and order of ideas. Nouns and verbs belong to the first class; prepositions, adverbs, &c., and the signs denoting the inflexions of verbs and nouns, to the latter. With respect to the former class, all languages, to be serviceable for the purposes of life, must be sufficiently copious to express all distinct notions. But the comparative richness of a language is mainly shown by the manner in which this is done. As nations advance from barbarism towards civilization new notions, and new varieties of notions, are constantly requiring utterance. In those in which this can easily be done by composition (as in Greek and German), great facilities are afforded for the easy expression of thought, comparatively with those in which it can only be effected by the laborious process of borrowing and adopting words from the vocabularies of more advanced nations.

But it is in the *relational* words, or modes in which relations of ideas are expressed, that the genius of different languages most varies. The Chinese, in their singular and obscure tongue, seem never to have reached beyond the process of varying the collocation of their unchangeable roots in the sentence, in order to express varieties of meaning. The next process should appear to be that of using auxiliary words. In many languages (our own among the number) relations are almost wholly expressed in this manner. But in others the auxiliary words have, in course of time, coalesced with the principal; so that many relations are expressed by varying the beginning, termination, &c. of the principal word. This, at least, is the most probable origin of those forms termed in grammar *inflexions*, or forms of declension and conjugation, in which Greek, Latin, Sanskrit, German, and their derivative languages are more or less rich; the Greek, for example, being more copious than the Latin or modern German, in having the dual form and additional tenses (the aorists, and the paulo-post futurum). And some languages (especially among the American Indians) are so curiously constructed as to carry the power of inflexion far beyond this point. A complex idea which, in English, would require to be expressed by a pronoun, an adverb, and an auxiliary verb (or perhaps a second auxiliary verb also, *e. g.* "I desire," or "I abstain"), together with the principal verb, would in some American languages be expressed merely by a variety of the form of the principal verb itself.

As a general rule, the power of inflexion adds greatly to the copiousness of a language; and although some enthusiasts in their admiration of our own have maintained that the process of conjugating or declining by auxiliary words and particles is more convenient, and affords more variety and harmony, than that by changes in the termination of the verb or noun, it is probable that few candid reasoners will hold the same opinion. But there are distinctions in language, arising out of relations simply imaginary, which may be pronounced unnecessary and cumbersome. Such are the genders, common to almost all languages of the Indo-European family except our own, but for which it would be difficult to assign either utility or beauty.

Another and a more substantial disadvantage of languages rich in inflexions, if the fact be true, is to be found in the greater difficulty which common people are supposed to have in framing their speech grammatically and accurately under this system than the other. The greater the niceties of a language, it has been urged, the greater the difference must inevitably be between the variety spoken and written by educated men and that in use among the uneducated; and it has been contended that in ancient Italy, for instance, the rustic language was altogether different from the written Latin. But the facts on which this reasoning rests may be pronounced extremely controvertible. There are certainly some grounds for the suspicion that there was an unusual difference between the vulgar and the polished Roman

tongue, at least in the later times of the empire; but if this was always the case, it is singular that Plautus and Terence should no where furnish us, by way of heightening the ludicrous, with instances of ungrammatical locution. The language of ancient Greece was more refined and inflective than that of Rome; and there is no appearance that there was a greater diversity between the speech of the peasant and the philosopher and rhetorician than in any modern country. In Attica the very reverse seems to have been the truth, since its most elegant writers and orators appear carefully to have modelled their language on the common dialect of their countrymen. And, finally, the wild Indian of America speaks with purity a language often surpassing in variety of inflexions those of the most civilized and illustrious nations of the Old World.

Among the numerous and valuable works which may assist the reader in acquiring a knowledge of the existing varieties of spoken tongues, may be mentioned *Vater's Linguarum Totius Orbis Index Alphabeticus*, 1815; *Marsden's Catalogue of Dictionaries, &c.*, 1796, and his *Miscellaneous Works* (as to Oriental languages); *Adelung's Mithridates*, already cited; the Works of Dr. Prichard; a very valuable article in the *Penny Cyclopædia*, of which much use has been made in the above pages.

LANGUE'NTE. (Ital.) In Music, a direction to the performer, when prefixed to a composition, denoting that it is to be performed in a languishing or soft manner.

LA'NIARIES, *Dentes Laniarii*. (Lat. lanio, *I rend.*) The long conical and sharp-pointed teeth which are placed next behind the incisors. They are also called *dentes canini* and *cuspidati*. They never exceed $\frac{1 \cdot 1}{1 \cdot 1}$ in number in the Ferine Mammalia.

LA'NIUS. (Lat. lanio.) A Linnæan genus of Passerine birds, forming the typical family of the Dentirostral division of that order in the system of Cuvier. The birds of the family *Laniadæ*, or shrikes, are characterized by a strong compressed conical beak, more or less hooked, and emarginate near the point, as in the other Dentirostres. The shrikes live in families, and fly irregularly and precipitately, uttering shrill cries; they build in trees, lay five or six eggs, and take great care of their young. They have the habit of imitating a part of the songs of such birds as live in their vicinity. The larger and stronger birds are predatory, and attack, slay, and devour smaller birds.

LA'NSQUENETS, *Lansknechts*. The German infantry first raised by the Emperor Maximilian to confront that of the Swiss, in the end of the fifteenth century. The name is derived from the German words *landes knecht*, countryman or country lad; and not, as is sometimes stated, from *lanz*, a lance or pike. The lansknechts were very irregularly armed; the greater part with pikes, but certain companies in every division with muskets. They were raised by voluntary enlistment, and their leaders passed with little reluctance into the service of any power which was willing to pay them. This infantry played a conspicuous part in the wars of Italy, in the first half of the sixteenth century, after which the name fell into disuse.

LANTA'NIUM. (Gr. λανθανειν, *to conceal.*) A metallic substance discovered by Mosander in *cerite*; it is associated with, and concealed as it were by, the oxide of cerium. The oxide of lantanium is of a brick-red colour.

LANTERN. (Fr. lanterne.) In Architecture, a drum-shaped erection, either square, circular, elliptical, or polygonal, on the top of a dome, or on that of an apartment, to give light. *See* Cupola.

LA'NTERN, MAGIC. *See* Magic Lantern.

LA'NTERN WHEEL. In Mechanics, a kind of pinion, having, instead of leaves, cylindrical teeth or bars, called *trundles*, or spindles, on which the teeth of the main wheel act. The ends of the trundles being fixed in two parallel circular boards or plates, the lantern wheel has the form of a box or lantern; whence the name.

LA'NYARD. The sea term for certain lashings, whether fixed or temporary.

LAO'COON. In Fabulous History, the priest of Apollo or Neptune during the Trojan war. While he was engaged in sacrificing a bull to Neptune, two enormous serpents sent by Minerva, in revenge for his having endeavoured to dissuade the Trojans from admitting the famous wooden horse within their walls, issued from the sea; and having fastened on his two sons, whom he vainly endeavoured to save, at last attacked the father himself, and crushed him to death in their complicated folds. Virgil has thus described the occurrence: —

——— Et primum parva duorum
Corpora natorum serpens amplexus uterque
Implicat, et miseros morsu depascitur artus:
Post, ipsum, auxiliis subeuntem ac tela ferentem
Corripiunt, spirisque ligant ingentibus: et jam
Bis medium amplexi, bis collo squamea circum
Terga dati, superant capite, et cervicibus altis.

This story has gained immortal celebrity from its forming the subject of one of the most beautiful groups of sculpture in the whole history of ancient art. The composition is pyramidal, and represents Laocoon and his two sons writhing and expiring in the convolutions of the serpents. Agony in an intense degree is exhibited in the countenance and convulsed body of Lacoon, who is attempting to disengage himself from the serpents; and the sons are represented as imploring assistance from their helpless parent. Some connoisseurs, who have ventured upon a criticism of the group, have discovered that its complexity destroys its effect; but we doubt the value of their criticism, and to counteract it give the opinion of Fuseli (no mean judge), from his *Lectures on Painting*. "In the group of the Laocoon the frigid ecstasies of German criticism have discovered pity like a vapour swimming on the father's eyes; he is seen to suppress in the groan for his children the shriek for himself; his nostrils are drawn up to express indignation at unworthy sufferings, whilst he is said at the same time to implore celestial help. To these are added the winged effects of the serpent poison, the writhings of the body, the spasms of the extremities. To the miraculous organization of such expression Agesander, the sculptor of the Laocoon, was too wise to lay claim. His figure is a class; it characterizes every beauty of virility verging on age: the prince, the priest, the father, are visible; but, absorbed in the man, seem only to dignify the victim of *one* great expression. Though poised by the artist, for us to apply the compass to the face of the Laocoon is to measure the wave fluctuating in the storm: this tempestuous front, this contracted nose, the immersion of these eyes, and above all that long-drawn mouth, are, separated and united, seats of convulsion — features of nature struggling within the jaws of death."

Of this famous group of sculpture Pliny says, that it is "*opus omnibus picturæ et statuareæ artis preferendum.*" It was discovered at Rome among the ruins of the palace of Titus, at the beginning of the 16th century; and afterwards placed in the Farnese palace, whence it found its way to the Vatican. It was executed by Polydorus, Agesander, Athenodorus, the three celebrated artists of Rhodes. The *Penny Cyclopædia* has an excellent article on this subject, to which we beg to refer.

LAPIDARY STYLE (Lat. lapis, *a stone*), denotes the style proper for monumental or other inscriptions, and is thence sometimes used to express a terse, expressive style. The rules of this style have been prescribed by Cicero: — "Accedat oportet oratio varia, vehemens, plena spiritus. Omnium sententiarum gravitate, omnium verborum ponderibus est utendum."

LAPI'LLI. (Lat. lapillus, *a little stone.*) Small volcanic cinders.

LA'PIS. (Lat.) In Roman Antiquity, literally a stone; but used among the Romans to signify a mile, at the end of which lapides or stones were erected with a mark thereon to show the distance from Rome. Hence the phrases "tertius lapis," "centesimus lapis," &c., for 3, 100, &c. miles; and sometimes even the ordinal number was used, with *lapidem* understood, as "ad duo decimum," — twelve miles distant. The Roman practice of indicating the distance of one place from another by the erection of stones has been borrowed by almost all the nations of modern Europe.

LA'PIS CAUSTICUS. Caustic potash.

LA'PIS INFERNA'LIS. Fused nitrate of silver; often called *lunar caustic*.

LA'PIS LA'ZULI. A blue mineral found in masses or nodules, consisting chiefly of silica and alumina, with about twenty *per cent.* of soda, and some peculiar combination of sulphur, to which it probably owes its colour; it is often sprinkled with yellow pyrites It furnishes the valuable pigment known under the name of *ultra marine*, and was formerly much employed in ornamental inlaid work. Persia, China, and Russia are its chief sources.

LA'PITHÆ. In Ancient Geography, a people of Thessaly, chiefly known to us from their fabled contests with the Centaurs. The battle between the Centaurs and the Lapithæ has been described by Hesiod, and by Ovid with great minuteness. (*Met.* xii.) To the Lapithæ has been attributed the invention of bits and bridles for horses.

LAPSE (Lat. lapsus, *a slip*), in Ecclesiastical Law, is the omission of a patron to present a clergyman to a benefice within six months after its being void; in which case the benefice is said to be void, and the right is lost to the patron. In England the right of presentation then accrues to the bishop, and to the sovereign by the neglect of these; and in Scotland it devolves on the presbytery.

LA'PWING. The name of a native species of the genus *Vanellus*, dismembered by Bechstein from the *Tringa* of Linnæus. (*See* Vanellus and Tringa.) The lapwing or pee-wit (*Vanellus cristatus*, Bechst.) is a constant inhabitant of this country; subsists chiefly on worms and the animalcules of the sea-shore, which it frequents

in great numbers. The female makes a simple nest by scraping together a little dry grass, and deposits thereon four eggs, of a dirty olive colour spotted with black. The young birds are covered with a thick down when hatched, and soon begin to run about: at the approach of danger they squat down, and the parent, by a curious instinct, endeavours to attract the attention of the intruder, and draw him away from the spot, by fluttering about with cries of inquietude, or even running along the ground as if lame. In October the lapwings are fat, and in good condition for the table: their eggs are considered a great delicacy.

LA'QUEAR. In Architecture. *See* LACUNAR.

LARA'RIUM. (Lat.) In Ancient Architecture, the apartment in which the lares or household gods were deposited; it also frequently contained statues of the proprietor's ancestors.

LA'RBOARD. The left-hand side of a ship to a person whose face is turned towards the head. The other side is called the *starboard*.

LA'RCENY. (Lat. latrocenium, *theft.*) In Law, a species of felony, distinguished, formerly, into simple and mixed: the latter of which was the taking of goods and chattels from the person, or from the house, if above the value of twelve-pence. But this distinction has been abolished by the statute which consolidated the laws relative to this class of offences (7 & 8 G. 4. c. 29.). Larceny is the felonious and fraudulent taking and carrying away of the goods and chattels of another. Thefts of things affixed to the freehold, if forming part of what is termed real property, are not larceny at common law; but many offences of this description have been brought within the character of larceny by enactment. Robbery, breaking into and stealing in a dwelling-house, if in the daytime, piracy, &c., are species of mixed larceny. A receiver of stolen goods is indictable either for a substantive felony, or as accessary to the theft or robbery. Many of the offences under this class are still punishable by death; but in these, and all felonies except murder, sentence of death, instead of being pronounced immediately, may be recorded, to enable the judges to pronounce eventually a discretionary sentence according to the merits of the case.

LA'RES. (Lat.) Domestic deities of the Italians, who were probably regarded as the souls of the deceased ancestors of a family. Their worship, however, was not confined to private houses; as there were lares of the city, the country, roads, &c. *See* PENATES.

LARGE. (Ital.) In Music, a character representing the greatest measure of musical quantity; one large containing two longs, one long two breves, one breve two semibreves, and so on in duple proportion.

LARGHE'TTO. (Ital. dimin. of largo.) In Music, a movement a little quicker than *largo*.

LARGO. (Ital.) In Music. *See* ALLEGRO.

LA'RIDÆ. A family of swimming birds, having the gull (*Larus*) as the type.

LARK. The common name of the native species of the genus *Alauda* of Linnæus; of which one, the *Alauda arvensis*, is distinguished as the sky-lark or lavrock; the other, *Alauda campestris*, Linn., is called the field-lark. As the species of the present genus differ from most other Insessorial birds in resting habitually and sleeping upon the ground, their feet present a singular but simple modification, which at the same time beautifully adapts them to their office of supporting the superincumbent body on a flat surface: it consists in the extreme elongation in an almost straight line of the claw of the hinder toe, which is, at the same time, proportionally robust; thus the plane of support is extended at the expense of the prehensile faculty, which the habits of the lark render of little or no value to it.

The sky-lark is universally admired for the power and melody of its song, and for the beautiful associations inspired by the circumstances under which its notes are most richly poured forth — viz. while soaring aloft to greet the rising sun. It ascends in the air almost perpendicularly, by successive flights, to an elevation at which its song becomes inaudible: its descent is generally oblique. The female builds her nest on the ground, and lays four or five eggs, which are of a greyish brown colour marked with darker spots: she sits about fifteen days, and usually rears two broods in the year. This prolific species is granivorous, and in the winter large flocks congregate together; they are very fat at this season, and are captured in great numbers for the table.

LA'RMIER. (Fr.) In Architecture, the same as *corona*, which see.

LA'RUS. (G. λαρος, *a gull.*) A Linnæan genus of aquatic birds belonging to the Longipennate division of Palmipedes in the system of Cuvier, and now raised to the rank of a family comprising several subgenera. The *Laridæ*, or gulls, are characterized by their compressed elongated pointed bill, of which the superior mandible is curved downwards near the end, and the inferior forms a salient angle beneath. The nostrils, placed near its middle, or a little more forwards, are long, narrow, and form a complete transverse perforation; the tail is ample, and sometimes pointed. (*Lestris.*) The gulls are common and numerous on the sea-coast, and feed on the different animal substances which are left on shore or float down with the ebbing tide. The black-headed gull (*Larus ridibundus*, Linn.) breeds on the marshy edges of rivers or fens; the female makes her nest, among the reeds and rushes, of heath or dried grass, and lays three or four eggs, of an olive brown colour spotted and streaked with dusky red. When the young are able to accompany the parents they all resort to the sea-shore. The other species of gulls build for the most part in the sand or the clefts of rocks.

LA'RVA. (Lat. larva, *a mask.*) A Metabolian insect in its first stage after exclusion from the egg is so called, because its real form is, as it were, masked: the same term is also applied to those reptiles which undergo a metamorphosis, as the frog, when at a corresponding period of existence.

LARVA. Spectres of the deceased were so termed by the Romans: mere empty forms or phantoms, as their name indicates; yet endowed with a sort of existence resembling life, since they were to be propitiated by libation and sacrifice. The larva of Caligula, according to Suetonius, was often seen in his palace after his decease. The larvæ are described by Seneca, and often represented in paintings and on gems under the figure of skeleton; sometimes under those of old men, with shorn locks and long beards, carrying an owl on their hands.

LARVI'PARA. (Lat. larva, and pario, *I bring forth.*) Those insects are so called which bring forth larvæ instead of eggs, the latter being hatched in the oviduct.

LARYNGI'TIS. Inflammation of the larynx. The symptoms are hoarseness, sense of suffocation, great anxiety and restlessness, and spasmodic difficulty of deglutition. The acute form of the disease sometimes terminates fatally in 24 hours. Chronic inflammation of the larynx is not an uncommon complaint, and often a very troublesome one; it is frequently met with among dram drinkers: low diet, abstinence from spirituous liquors, and astringent lozenges and gargles generally relieve it; the acute form of the disease requires local and general bleeding, and a blister on the external throat.

LARYNGO'PHONY. (Gr. λαρυγξ, and φωνη, *the voice.*) The sound of the voice as heard by applying the stethoscope over the larynx.

LARYNGO'TOMY. (Gr. λαρυγξ, and τεμνω, *I cut.*) The operation of making an opening into the larynx. *See* BRONCHOTOMY.

LA'RYNX. (Gr. λαρυγξ.) The upper extremity of the trachea. It is a cartilaginous cavity, the superior opening of which is called the *glottis*. Its various parts, anatomically considered, are extremely complex and intricate, especially in reference to its construction and physiology as the organ of voice.

LA'SCARS. The name given to the native Indian sailors, many of whom are in the service of our mercantile navy.

LA'SER. A gum resin greatly esteemed by the ancients, and obtained from the north of Africa. It is described by Dioscorides (lib. iii. c. 48.); and, under the name of *silphion*, by Theophrastus. Different names were given to different parts of the plant which affords it, the term *laser* or *lasoorn* being exclusively applied to the inspissated juice. From the representations of the plant, upon the coins of Cyrene, it appears to have been one of the *Umbelliferæ*. According to Dr. Lindley (*Flora Medica*, p. 52.), it was in all probability obtained from *Thapsia asclepium*.

LAST. In Commerce, a measure of uncertain quantity, varying in different countries and with respect to different articles. Generally, however, a last is estimated at 4000 lbs. (See *Commercial Dictionary*.)

LATEE'N SAIL. A peculiar sail having a long yard much inclined to the horizon, and used by polacres, kebecs, and other vessels navigated in the Mediterranean.

LA'TENT HEAT. Heat insensible to the thermometer, upon which the liquid and aëriform states of bodies depend, and which becomes *sensible* during the conversion of vapours into liquids and of liquids into solids. *See* HEAT.

LA'TERAL OPERATION. A surgical term applied to one of the methods of cutting for the stone.

LA'TERAN. A church at Rome, the Pope's see, and the metropolitan of the whole world, dedicated to St. John Lateran. The name is derived from the Roman family of the Laterani, who possessed a palace on this spot, which was seized by Nero, and became from his time an imperial residence. The Lateran palace was given by Constantine to the popes (see *Milman's Hist. of Christianity*, ii. 361.), who continued to inhabit it until their retirement to Avignon, when it was exchanged for the Vatican. The building was then converted into a church. Eleven councils have been held in the Basilica of this name (hence styled Lateran councils in ecclesiastical history), of which four are considered by

the Roman Catholics to be general. The last of these (or the 12th General, according to the same computation) is the most celebrated. It was held in 1215 by Innocent III., and is principally famous as establishing the Roman Catholic doctrine of the Eucharist, using for the first time the term transubstantiation for the change of the elements. This council was convoked on the occasion of the heresy of the Albigenses, and its exposition of the Catholic faith is directed principally against them. It established also some canons for the maintenance of discipline among the clergy, and that (omnis utriusque sexus) which enforces confession and communion upon all the faithful at least once a year.

LATERI'TIOUS. (Lat. later, *a brick.*) This term is applied to the reddish sediment which is often deposited by the urine.

LA'TEX. (Lat.) A term given to a peculiar fluid found in certain vessels that have been discovered by Schultz to be present in plants. It is as yet but little understood, but is described by its discoverer as a peculiar secretion having a rapid vital motion, and containing numerous granules of organizable matter. He supposes it to be analogous to the blood in cold-blooded animals. What is usually denominated the milk of plants appears to be latex.

LATH. (Sax. lætta.) In Architecture, a thin cleft piece of wood used in slating, tiling, and plastering. There are two sorts of laths, single and double; the former being barely a quarter of an inch, whilst the latter are three eighths of an inch thick. Pantile laths are long square pieces of fir on which the pantiles hang.

LATHE. A Saxon territorial division, of which the etymology is uncertain. Kent is the only county divided into lathes, each of which contains four or five hundreds. Each was originally under the jurisdiction of a lathe-reeve, subordinate to the sheriff of the county. *Lathe* is also the name of a well-known instrument or engine used in turning wood, ivory, or other materials.

LATH FLOATED AND SET FAIR. In Architecture, three-coat plasterer's work; in which the first is called pricking up, the second floating, the third or finishing is done with fine stuff.

LATH LAID AND SET. In Architecture, two-coated plasterer's work; except that the first is called *laying*, and is executed without scratching, unless with a broom. When used on walls this sort of work is generally coloured; when on ceilings it is white.

LATH PLASTERED, SET, AND COLOURED. In Architecture, the same as lath laid, set, and coloured.

LATH PRICKED UP, FLOATED, AND SET FOR PAPER. The same as lath floated and set fair.

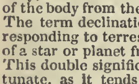
LA'TICLAVE. (Lat. lavus clavus.) The broad stripe which Roman senators and patricians were privileged to wear on their robe.

LATI'SSIMUS DORSI. A broad muscle of the back which pulls the os humeri downwards and backwards, and assists in its rotatory motion.

LA'TITUDE (Lat. latitudo, *breadth*), in Geography, signifies the distance of a place from the equator, expressed in degrees of the earth's circumference; or it is the angle which a line perpendicular to the horizon of any place makes with the plane of the earth's equator. In Astronomy the term latitude, as applied to a celestial body, has a different signification, and means the distance of the body from the ecliptic, or plane of the earth's orbit. The term declination is applied to denote the angle corresponding to terrestrial latitude; namely, the distance of a star or planet from the plane of the earth's equator. This double signification of the term is extremely unfortunate, as it tends to create a confusion of ideas; but having been introduced by the early astronomers, and being ingrafted into every existing work on the science, it is now too late to remedy the evil.

Latitude and longitude being the co-ordinates by which the positions of places on the terrestrial surface are defined, their determination forms the most important application of astronomy.

In order to give an idea of the methods of finding the latitude of a place, or of a ship at sea, it is necessary to recal some of the elementary properties of the sphere.



Let H H' be the horizon of a spectator placed at C; C P the direction of the axis of the earth's rotation; and C Z the direction of the zenith, or perpendicular to the horizon. Let C E be drawn perpendicular to C P, in the plane determined by the straight lines C P and C Z, or the plane of the meridian; then C E is the intersection of the planes of the equator and meridian; the semidiameter of the earth being neglected as infinitely small in comparison of the distances of the stars, to which C P, C Z, and C E are supposed to be prolonged.

Now, by the definition, the angle E C Z is the latitude of C; and it is this angle, therefore, which is to be determined. The observer always knows his zenith by the direction of the plumb-line; but there is no visible mark in the heavens by which he can at all times determine the place of the equator, or the position of E in the meridian, or even the meridian itself. But the angles E C P and Z C H being each right angles, E C Z is equal to P C H; that is to say, the latitude of the place is equal to the height of the visible pole. Now the pole is a fixed point in the heavens, and its position (in the northern hemisphere) is indicated nearly by a star, called the pole star, or *polaris*, which describes a small circle of the sphere within $1^{\circ}\ 40'$ of it. By observing, therefore, the height of the pole star at any place, an approximation to the latitude will be obtained within $1^{\circ}\ 40'$ of its true value. But this approximation is very far from being sufficient for any useful purpose.

The places of the principal stars being given in the existing catalogues, the observed altitude of any one of them at the time it passes the meridian will give the latitude of the place. Let S be a star on the meridian, and S P its polar distance in the catalogue, and let its altitude H' S be observed; then H' S being known, S Z, the zenith distance, is also known; and S P being also known, we have S P − S Z = Z P, the complement of the latitude. In like manner, the latitude may be found by observing the meridional altitude of the sun, or moon, or a planet, the declinations of all these bodies at any time being known. But though all the methods are equally good in theory, they are not all equally practicable, and some of them give a result attended with much greater uncertainty than others. The following are those which are chiefly employed.

1. By observing the altitude, or, which comes to the same thing, the zenith distance, of a star on the meridian. This is the simplest in practice, requiring only a single observation, and no other correction than for refraction. It is accordingly generally employed for common geographical purposes. When the sun or planets are the bodies observed, corrections must also be applied for the semidiameter of the body and for the parallax. At sea the bodies selected are the sun and moon, the observation of a star or planet being difficult on account of the motion of the vessel. To know when a heavenly body is on the meridian, it is necessary to have a pretty accurate knowledge of the time; but it may be remarked that near the meridian the altitude varies very slowly, and therefore a small error in respect of the time does not much affect the result.

2. By the altitudes of the circumpolar stars (those which never go below the horizon of the place) at their upper and lower transits. If the altitude of a star on the meridian is observed both above and below the pole, the sum of the two altitudes is equal evidently to twice the height of the pole, or twice the latitude. The only correction required is for refraction, which is not the same in the two observations.

3. The latitude may also be found by observing the greatest and least meridian altitudes of the sun in the course of a year. The sum of the altitudes of the sun at the summer and winter solstices is equal to twice the height of the equator, or twice the complement of the latitude; but this method requiring observations to be made at an interval of six months, is seldom had recourse to, excepting in fixed observatories.

4. All the preceding methods suppose the body observed to be on the meridian; but this condition, though it renders some calculation unnecessary, is not indispensable. The latitude may be determined by the observed altitude of a body out of the meridian; and indeed with more certainty, because several observations may be made successively, the mean of which will give a surer result than a single meridional observation. Let P be the pole, S the

place of the star or planet, and S Z its observed zenith distance, or the complement of its observed altitude. In the triangle P S Z, P S, the polar distance of the star, is known; S Z is given by observation; and the hour angle Z P S is given, because the time of the observation is supposed to be exactly known; therefore P Z, the co-latitude, may be found by the solution of a spherical triangle. This method, however, can only be successfully applied by observing near the meridian, and some artifices of analysis are required to adapt the trigonometrical formulæ to calculation. A method has lately been proposed by Professor Littrow of Vienna for determining the latitude by means of observations of the pole star off the meridian, which is found to be of great practical utility.

5. The last method which we shall notice for finding the latitude is one that has been proposed by Bessel, and consists in observing the eastern and western passages of a star through the prime vertical; that is, the vertical plane at right angles to the meridian. When a transit instrument is adjusted to move in this plane, and consequently has its horizontal axis in the direction of the meridian, all the stars which pass the meridian between the zenith and equator will twice enter the field of the telescope. Now let t be the time of the eastern transit, t' the time of the western transit, δ the declination of the star, φ the latitude, and P the diurnal arc corresponding

to the time $\frac{1}{2}(t-t')$; then the formula by which the latitude is determined is

$$\tan.\,\phi = \frac{\tan.\,\delta}{\cos.\,P}.$$

The advantages of this method are, that the observations may be made with a portable instrument, which can easily be oriented by means of the circumpolar stars; a small error in the adjustment will produce no sensible error in the result if the stars observed pass near the zenith; the observations are altogether independent of errors in the division of the instrument; and in determining differences of latitude. errors of declination are also eliminated by observing the same stars at all the stations. It is therefore a very convenient method for a trigonometrical survey.

LATITUDINA'RIANS. In Eccl. History, a class of English divines in the reign of Charles II., opposed alike to the high tenets of the ruling party in the church, and the fanaticism which then distinguished so many of the Dissenters. They were of course the objects of much attack; and one of their number, Fowler, Bishop of Gloucester, explained their principles in his treatise entitled "*The Principles and Practice of certain modern Divines of the Church of England, vulgarly called Latitudinarians, truly represented and defended, by way of Dialogue.* 1670." Henry More, and the other Platonizing divines of the time, were sometimes comprehended under this appellation. (See *Mosheim*, vol. v. p. 412., transl., ed. 1790.) The word has been since very generally used to designate those who hold opinions at variance with the more rigid interpretation of Scripture and church traditions, or merely as a term of party vituperation.

LA'TROBITE. A mineral found on the coast of Labrador, and also in Finland. It is translucent, of a pale red colour, and occurs both crystallized and massive. It is a silicate of alumina with lime, potash, and oxide of manganese.

LA'TTEN. (Fr. laiton.) Brass or bronze. Tinned iron is also sometimes known under this name.

LA'TUS RE'CTUM. In the Conic Sections, the same with parameter. — *Latus transversum*, the same with the transverse axis. See Conic Sections.

LAU'DANUM. (Supposed to be derived from Lat. laus, *praise*.) Different preparations of opium have been so termed: the tinctures used formerly to be called *liquid laudanum*.

LAUDICOENI (Lat.), among the Romans, were persons who (like the modern claqueurs in France, or the puffers in England at auctions) attended the performance of plays and the delivery of orations, in order to raise or to join in the acclamation. The derivation of the word would indicate that an entertainment was the chief, if not the only reward, which they obtained for their services.

LAUDS. (Lat. laudes, *praises*.) In the Roman Catholic Church, the prayers formerly used at daybreak, between those of "matins" and "prime." In later times they have become generally confounded with "matins."

LAU'MONITE. A variety of zeolite, named in honour of its discoverer, Gillet-Laumont. It crumbles when exposed to air in consequence of loss of water. It is a silicate of alumina and lime with 16 per cent. of water.

LAUNCH. The putting of a new vessel into the water. When the vessel is to be launched, a frame called *cradle* is built under her, thus: — At about one third of the extreme half breadth are laid, on each side of the keel and parallel to it, long pieces of timber, forming, as it were, two keels under the principal portion of the vessel. On these are placed vertical timbers meeting the ship's bottom, and maintained from slipping outwards by a strong plank or ribband. This apparatus, which is the cradle, rests on each side upon a platform sloping to the water; these platforms are called *the ways*, and are greased. The blocks on which the keel was laid being removed with the shores, the vessel rests on the cradle, which is kept from sliding down by a small piece or bar of wood fixed to it lying nearly horizontal, abutting against a place in the ways called the *dog shore*, which being struck downwards falls, and the vessel slides down into the water. When afloat, she is rolled from side to side by the persons on board to disengage the cradle.

Launch. A wide and flat boat, the largest carried by a man-of-war.

LAURA'CEÆ. (Laurus, one of the genera.) A natural order of arborescent Exogens, inhabiting the cooler parts of the tropics and some temperate countries. They are distinguished from all other incomplete apetalous Exogens, excepting *Atherospermaceæ*, by the peculiar dehiscence of the anthers, which open in consequence of the face of the valves rolling back; and from that order by the ovules being pendulous, not erect. The species are generally tonic and stimulant. Cinnamon and cassia are the produce of some, camphor of others, and the common sweet bay is a frequent instance of the order in the northern form. A few are so aromatic that their seeds have been used as substitutes for nutmegs.

LAU'REATE. (Lat. laureatus.) Literally crowned with laurels; applied at present to a well-known officer in the royal household. At the Certamina, or gymnastic and other contests celebrated under the Roman emperors, especially at the Quinquatria, or Feast of Minerva, poets also contended, and the prize was a crown of oak or olive leaves. But it was from some traditionary belief respecting the coronation of Virgil and Horace with laurel in the Capitol (of which, however, no record is extant) that the dignity of poet laureate was invented in the 14th century, and conferred on Petrarch at Rome by the senator or supreme magistrate of the city. It was intended to confer the same honour on Tasso, who, however, died on the night before the proposed celebration. In 1725 and 1776 it was granted to two celebrated improvisatori, the Signor Rufetti and the Signora Morelli, better known by the name of Corilla (*see* Improvisatori). In most European countries the sovereign has assumed the privilege of nominating a court poet with various titles. In France and Spain these have never been termed poets laureate; but the imperial poet, or Poeta Cesareo, in Germany, was invested with the laurel. This crown, however, was customarily given at the universities in the middle ages to such persons as took degrees in grammar and rhetoric, of which poetry formed a branch; whence, according to some authors, the term Baccalaureatus (quod vide) has been derived. In England traces of a stipendiary poet royal are found as early as Henry III., and of a poet laureate by that name under Edward IV. Skelton, under Hen. VII. and VIII., was created poet laureate by the universities of Oxford and Cambridge, and appears to have held the same dignity at court; but the academical and court honour were distinct until the extinction of the university custom; of which Henry VIII.'s reign exhibits the last instance.

Royal poets laureate are supposed not to have begun to write in English until after the Reformation. The office was made patent by Charles I., and the salary fixed at 100*l*. annually, and a tierce of Spanish Canary wine. Under Queen Anne it was placed in the control of the lord chamberlain. In the reign of George III. the annual tierce of wine was commuted for an increase of salary, and at the close of the same reign the custom of requiring annual odes from the lord chamberlain was discontinued.

LAURINE. A fatty matter of an acrid taste, contained to the amount of about 1 per cent. in the berries of the common laurel.

LA'VA. The substances which flow in a melted state from a volcano. They vary considerably in texture and composition. *See* Geology.

LAVER. (Lat. lavo, *to wash;* because washed by the waters of the ocean.) A species of *ulva* which is eaten as a delicacy.

LAW, in Latin *Lex;* derived from the verb *lego*, I collect or select.

Law, collective and particular. — We employ the term "law" to denote a body of rules, or all the rules applicable to a given subject; *e. g.* the Roman Law, the Law of Nature. We employ the term "a law" to denote an individual rule.

The idea of law, in its strictest sense, comprehends the notion of two parties; a superior imposing it, and an inferior obeying it.

Laws, improperly or metaphorically so called. — In common language it is usual to apply the word "law" to designate principles or properties which can only be thus named by analogy. Whenever certain causes invariably or generally produce like effects, this consequence of effect upon cause is popularly termed "a law." Thus we speak of the *law of nature* with reference to inanimate or irrational subjects; of the *law of gravitation*, by which bodies are mutually attracted to each other; of the *laws of motion*, of the *laws* which regulate certain processes in animal and vegetable economy, &c. In this sense, laws have been defined to mean "the necessary relations resulting from the nature of things." The analogy is nobly expounded in a well-known passage of *Hooker's Ecclesiastical Polity*, at the end of the first book.

Law defined. — Law, in its stricter sense, as applied to the voluntary actions of man, comprises the notion of a command issued by a superior imposing an obligation on a subject.

Laws, Divine and Human. — Laws are divided, according to the superior who imposes them, into divine and human: the law of God, and the law of man.

Divine Law. — The Author of our being has declared his will to mankind at various times, through the instrumentality of inspired prophets and teachers. There are also certain rules of right and wrong commonly received, which are generally supposed to have their origin in the nature of man, and to subsist independently of God's revealed will. Thus the term "divine" law signifies, 1. Revealed law; 2. Natural law.

Revealed Law. — God, as the Lawgiver of the Jewish nation, dictated to Moses a code of laws for that people, comprising both a confirmation of such laws as are

commonly considered natural by specific sanctions, and also various minute ceremonial and social observances. Thus the Jewish law is commonly said to consist of, 1. The moral law; 2. The ceremonial law; 3. The civil or political law.

Law of Christianity.— The second branch of revealed law is that which is declared to us in the New Testament.

Law of Nature. — The law of nature, however extensive in its philosophical meaning, is much more confined in that sense in which alone it is within the province of jurisprudence. Regarding it as merely applicable to the relative duties of men in a community, it is sufficient for practical purposes to observe, with Grotius, that its first principle is the sociability of man; and, consequently, that the conservation of society in its actual state, whether from the motive of mutual distrust, as Hobbes maintained, or from innate benevolence, as his adversaries contended, is the duty which it imposes on every one.

Let us suppose, therefore, that in a community such as our own there could occur at once a suspension of all civil positive law; and that, at the same time, the sanctions of God's revealed law could be withdrawn. Men would thus be restored to a state of natural liberty. The natural law is that code of duties which would then take the place of all other legislation. Every act tending to injure our neighbour in person and property, every act in any way tending to disturb or impair the frame of society, would then be prohibited by natural law, as it now is prohibited by laws human and divine. Undoubtedly the natural law, in the sense in which it is commonly used, comprehends a far wider range of objects. The duties of personal holiness, the relative duties of the members of a family, the duties of active benevolence; all these are dictated to us by conscience, as much as abstinence from positive injustice. But the province of jurisprudence is too limited to admit of the consideration of these higher parts of morality; it is with political society only that she is concerned.

Law of Nations.— The principle of natural law between individuals in a community would thus be the maintenance of the status quo, or actual condition of things, and the insuring to every one the continuance of all his possessions. This, therefore, is the elementary dogma of that only branch of natural law which can be said to exist as a definite rule of conduct; namely, the law of nations. Nations are in a state of natural liberty with reference to other nations. For, since they have no earthly superior to establish rules for them, and since the decrees of Christianity, addressed as they are directly to individuals, have been generally discarded in the practice of collective bodies, the only maxims which govern their intercourse are certain conventional arrangements, the object of which is the maintenance of the existing society and intercourse between the subjects of distinct sovereign states. All the rules of national law have this for their ultimate end. The natural law of men, to use the phrase of Hobbes, teaches the absolute duties subsisting between men and men; the natural law of nations, those subsisting between men in societies: or (in a compendious definition), national law is the law of nature applied to independent states as if they were individuals.

The law of nations, according to the comprehensive arrangement of Mackintosh, comprises "the principles of national independence, the intercourse of nations in peace, the privileges of ambassadors and inferior ministers, the commerce of private subjects, the grounds of just war, the mutual duties of belligerent and neutral powers, the limits of lawful hostility, the rights of conquest, the faith to be observed in warfare, the force of an armistice, of safe conducts and of passports, the nature and obligation of alliances, the means of negotiation, the authority and interpretation of treaties of peace."

But the law of nations, in its practical sense, widely differs from this extensive and philosophical compendium of international duties. Many of the maxims which relate to the subjects here enumerated belong rather to the the higher province of morality than to that of jurisprudence. The only punishment of which the sanction can be applied in this species of law is the hostility of other states towards that which violates it. Whoever, therefore, is powerful enough, whether from his own strength or from position and alliances, to defy such punishment, is, in a certain sense, above the law. Hence, although the law of nations, considered as a branch of that of nature, would lay down absolute rules of conduct in the highest as well as the lowest matters of policy within its reach, it may safely be said that the law of nations as a body of recognized right extends only to a portion, and that the least important, of these matters. The only maxims which can be said to subsist as laws are those which are never or rarely violated by European states; because the inconvenience of their general neglect would overbalance the particular inconvenience of adhering to them in a given instance. Thus all will acknowledge that there is a wide difference, in point of preciseness and obligation, between the principles which forbid unjust aggression or severity towards the conquered, and those which prescribe the privileges of ambassadors and the protection of peaceful aliens.

The subjects to which national law is most strictly confined are customary rules respected by the mutual consent of nations, rarely infringed by the voluntary act of a sovereign power, and of which the infringement is considered to require satisfaction and reparation.

It is to be observed, that although several of the maxims of national law (such, for example, as the sanctity of the persons of ambassadors) are usually held binding in transactions with all nations of the globe, yet the great bulk of its rules are only recognized and observed by the Christian states of Europe and America in their dealings with each other.

National law (from its defective sanction and want of a sovereign legislator as to its details) may, perhaps, be more properly termed the custom than the law of nations.

The reduction of the law of nations to a system was first made by Grotius, in a work which, as Sir J. Mackintosh has well observed, though we now indeed justly deem it imperfect, is perhaps the most complete that the world has yet owed, at so early a stage in the progress of any science, to the genius and learning of one man. To him succeeded Puffendorf; who, avoiding the inconvenient and unscientific method of Grotius, has, to use the words of the statesman already quoted, without the genius of his master, and with very inferior learning, yet treated the subject with sound sense, with clear method, with extensive and accurate knowledge, and with a copiousness of a detail sometimes indeed tedious, but always instructive and satisfactory. But, in addition to the works of these illustrious authors, the rules of national law are to be found, first, in the treatises of several other authors, who are usually regarded as authorities; of whom Bynkerschoek (*Opera Omnia*, fol. Lug. Bat. 1767; Engl. Trans., fol. 1749), Vattel, Wicquefort, Rutherforth (*Institutes*, 1779), Von Martens, and others, may be cited: secondly, in the treaties which have been at different times concluded between European states; especially those of Westphalia, 1648; Utrecht, 1713; Aix-la-Chapelle, 1748; Paris, 1763; and Vienna, 1814. A pretty complete summary of the bibliography of this subject will be found in the introductory chapter of Mr. Manning's work on the *Law of Nations* (1839). (See also Dr. Wheaton, on *International Law*, 2 vols. 8vo. Lond. 1836.)

The language of conventions and treaties has frequently given occasion to disputes. Subsequently to the revival of letters, and until the peace of Nimeguen (1679), the state language ordinarily used was the Latin; but since that period it has chiefly given way to the French, which is now commonly used between nations employing different languages in their public acts.

Law, Positive or Municipal. — This is the term usually employed to distinguish law, in its ordinary sense (the expression of the will of the supreme power in a state), from all the other species of law (improperly so called) with which we have hitherto been occupied. It is called *positive* law, because established in the form of direct and definite injunctions; *municipal*, from the Latin *municipium*, a town possessed of privileges and local laws.

Positive law is "a rule of civil conduct prescribed by the supreme power in a state." Blackstone adds, "commanding what is right, and prohibiting what is wrong." But as it is clear that the right commanded and the wrong prohibited acquire the character of right and wrong only from being so commanded and prohibited, the latter half of the definition is evidently comprehended in the first. A regulation or body of regulations, usually adhered to by men in their dealings with each other, but not commanded by the civil power nor enforced by lawful punishment, is properly called a custom; but when such regulations, whether set by men to each other on a footing of equality, or by subordinate bodies within the state to individuals, can be enforced by lawful punishment, the sovereign power allowing such punishment, the sovereign power thereby adopts the regulations, and they become laws in the strictest sense of the word.

A law is also defined, "a command of a political superior obliging the subject to a particular course of conduct." This definition comprehends most of the civil institutions with which jurisprudence is concerned; but it appears to exclude some which are nevertheless within the province of that science. For example,—

1. Many laws are enacted to explain former laws, and also to repeal former laws. Neither of these can be said, in strictness, to answer the definition of law which describes it as a command, unless we consider them as re-enacting former commands. 2. The Roman jurists applied the term "laws of imperfect obligation" to certain enactments of their law prescribing particular conduct, but without any penalty being expressed in the event of their violation. These were not commands, not being enforced, and could not be said to oblige the subject, who was at liberty to escape the obligation. Our laws recog-

nize no such rules as these. If a statute enjoins or prohibits an action without adding any express penalty, the courts of justice *presume* that a violation of the statute is punishable. Law, as the subject matter of jurisprudence, is that which obliges the subject to a particular *course* of conduct by *general* rules of action. This excludes —

1. Laws made to permit or restrain the acts of specified individuals. Such were called by the Romans *privilegia*, or, under the emperors, private rescripts; in our law, *private acts of parliament*. The sovereign body in the state, having the power to repeal and modify its own enactments, can by an expression of its will exempt particular persons from its own injunctions, or can impose new duties on particular persons. Such decrees have all the force of law; but they do not form a part of the general law of the country.

2. Laws made to suit a particular emergency, occasional or particular commands, which are distinguished from general laws by their *shorter duration*. To exemplify this difference, it has been said that should a sovereign command all his subjects to wear black as their ordinary dress, such a command would be a law; but should he order a general mourning for a stated time, such an order would not have sufficient permanence to entitle it to that appellation.

Every command given by a political superior is a law in point of force; but it is necessary to establish some distinction between occasional and general commands, as otherwise every direction of a public officer, every incidental command of a military superior must be considered as a law. An act to suspend the collection of a duty for a given time, an order in council to admit bonded goods or to issue any temporary regulations respecting trade and commerce, royal proclamations; all these are familiar instances of the species of occasional or particular commands.

Municipal law is commonly divided into two branches; that which concerns the public duties of individuals with reference to the state, and that which concerns the private relations of individuals towards each other. The division between these branches is not in all systems the same. Under the old Germanic institutions, for example, most crimes were considered as civil injuries only.

Laws, strictly so called, and forming the body of public right in each separate state, are to be found either in codes sanctioned by the authority of the state; or in decrees issued and made public by such authority; or, finally, in certain unwritten customs, to which that authority, by sanctioning them, has given the force of law.

The code of law, under all Mohammedan governments, is to be found wholly or in part in the Koran, which to Mohammedans bears the character both of revealed and civil law. Those of the Hindoos and many other nations have likewise the authority of an imaginary religious sanction.

In Western Europe the laws in force in most of its countries, although modified and republished by their several legislatures, are in great measure founded on what is termed the Roman law. This body of law is principally declared in the *Pandects*, *Code*, and *Institutes* of the Emperor Justinian; but these contain only a digest of a small portion of the laws which prevailed in the ancient Roman empire.

The Roman Law. — "Inasmuch," to use the words of our own learned judge Lord Holt, "as the laws of all nations are doubtless raised out of the civil law, as all governments are sprung from the ruins of the Roman empire, it must be owned that the principles of our law are borrowed from the civil law, therefore grounded upon the same reason in many things." — The manner in which the Roman law has been introduced into the jurisprudence of modern Europe may be said to have been twofold: first, through the prevalence of Roman usages, derived from the times of the empire, among the population of various countries, especially that part of it which was collected in towns; secondly, through the efforts of the ecclesiastics, who learnt the civil law from the *Codex* of Theodosius, and from the works of Justinian, and introduced it, as far as their authority extended, into such branches of justice as they were permitted to administer, and especially into their canon law, which the various princes of Europe permitted to be binding, to a different extent in different countries, upon their lay as well as clerical subjects. Thus the Roman law is in one sense the oldest and fundamental part of public right in many countries; in another sense, it is a comparatively recent importation, altering the character of their respective legislations. The Roman law comprises what are termed the *Institutes*, *Pandects*, *Code*, and *Novellæ*. (See these terms.) These have been collected and separately published, under the title of *Corpus Juris Civilis;* the best editions being those of Amsterdam (8vo. 1664) for the text, and of Gothofred (folio, Paris 1628) for the text and notes. The most elaborate modern work on the history of the Roman law is that of Savigny.

It would be impossible, within our limits, to give the reader any useful bibliographical notice on a subject which in foreign countries has necessarily received such abundant attention and illustration; and English treatise writers on the civil law are few, and of no great value, that law having only existed among ourselves, as we have seen, in certain limited departments.

Civil Law in England. — In England, while in the way of ancient custom there are fewer vestiges of the civil law than in any other of the provinces of ancient Rome, yet in the way of ecclesiastical jurisdiction it has been wider spread and continued longer in force than almost any where else.

Although Britain was a highly civilized province possessing 140 cities and towns in the time of the Romans, yet the numbers and violence of her invaders, especially the Saxons and the Danes, appear to have extinguished almost every relic of her provincial customs and jurisprudence. It is chiefly, therefore, to the clergy that we are to look for the prevalence of the civil law in England, and it has been introduced by them in several ways.

1. At the Norman invasion a considerable accession to the numbers and influence of the spiritual body in England took place. A century afterwards the discovery of the *Pandects* rendered the study of jurisprudence familiar chiefly among that body, who monopolized most of the learning and intelligence of the age. They introduced it into England; and, as the rude and simple justice of the Saxons was inadequate to meet the wants of the people, most of the early lawyers, who were themselves chiefly ecclesiastics, sought in the pages of their favourite works for principles to supply the defects as they arose. Hence, in the works of Bracton, Britton, and Fleta (written expressly on the common law of England, that is, the customary law of the Saxons modified by extensive introduction of Norman usages), we find constant reference not only in spirit but in words to the civil. The time during which the study of this latter was most in vogue among English lawyers appears to have been between the reigns of Stephen and Edward III. During the greater part of that period a constant struggle was carried on between the ecclesiastical lawyers, supported in many cases by the crown, and the popular party in favour of the old customary right, which was defended by the temporal nobility. The final victory of the common law, and its establishment as the rule of the land, except in particular cases, may be dated from the reign of Edward I.

2. The jurisdiction of the lord chancellor of England is a subject considered elsewhere. (*See* CHANCERY.) It is sufficient here to observe, that as most of the chancellors under the Plantagenet kings were ecclesiastics, and as the matters entrusted to their decision were such as the rules of the common law did not apply to, they generally searched for precedents in that of Rome; which has hence been largely imported into one great branch of modern English law, namely, Equity.

3. In some particular matters the rules of the civil law have always been allowed by custom to prevail in England. These are, such as were taken cognizance of by the courts of honour and chivalry, now fallen into disuse; in the High Court of Admiralty (*see* ADMIRALTY); and in the courts of the two Universities, which originally were ecclesiastical bodies.

4. The chief influence of the civil law in England has been through the canon law, which was founded upon it.

Law, Canon. — The rules which were framed by the Christian church for its own spiritual polity may be supposed to have had their origin in the very earliest periods of Christianity itself; but all the authority and force which they possessed could arise only from the mutual consent of the faithful to be bound by them, until the establishment of Christianity as a state religion entirely altered the character of its spiritual constitution. The temporal jurisdiction which was then too liberally conceded to the bishops, together with the legal force given by several emperors, Justinian in particular, to the canons of councils, gradually called into existence a new and independent body of legislation.

When the Western Empire had been overthrown, the authority of the popes, as temporal governors, was by degrees confirmed in the city of Rome and the adjacent country. At the same time the power of the ecclesiastical body was increased and extended in other countries; and the reverence attached to their authority gave to the spiritual censures with which they visited particular offences a greater force than to the sanctions of the national law. Thus, besides matters of church government, which were at first the particular subject of the pontifical law, it comprehended within its purview numerous and important branches of the civil law of persons and property.

About the year 1150, the various edicts then in force of the several popes, together with the canons of councils, and the authoritative declarations of fathers and doctors of the church, were collected together by the Monk Gratian, and reduced into a volume called the *Decretum*, and considered as the earliest authority in canon law.

In the next century, Pope Gregory IX. published five books of Decretals, collected from the Decretal Epistles of the Popes: to which Boniface VIII. added a sixth book, about the end of the same century. To these were added, at subsequent periods, the Clementine Constitutions, a seventh Book of Decretals, and a Book of Institutes. The whole of these authorities were collated and published by Gregory XIII. in 1580, under the title of *Corpus Juris Canonici*.

In matters of evidence, and as far as practicable in the forms of proceeding, the compilers of the canon law founded their system upon that of Rome, with which they were best acquainted. In all such matters of civil jurisdiction as their legislation embraced, they likewise assumed it as the basis of their structure. By the practice of all ecclesiastical courts the civil law is allowed to come in aid of and to supply the canon law, in all such cases as are there omitted. The subjects of the canon law were, 1. The hierarchy and government of the church; 2. All things relating to pious uses; 3. The wills of defuncts, the guardianship of orphans, and matters of marriage and divorce. But it was by no means permanently received, in most European countries, to its full extent. Its jurisdiction only subsisted by the toleration of princes; and therefore varied, according as the superstition or piety of these sovereigns, or their jealousy of ecclesiastical usurpation, alternately predominated. But, upon the whole, its authority became so deeply rooted, that even in countries which have rejected in later times the authority of the pope its rules are still referred to, not merely in matters relating to church benefices, but also in some cases of purely civil jurisdiction.

Nevertheless, although in early times its authority was asserted by the popes on the ground of their temporal superiority over all earthly sovereigns, its force in every country must now be said to depend upon the will of the state, which gives the force of law to its provisions.

It is supposed that the decrees and canons of the church of Rome were adopted in this country so early as A. D. 605, shortly after the introduction of Christianity among the Saxons; but they were not fully recognized by the state until after the Norman conquest. The bishops, who had in Saxon times sate with the sheriffs and landed proprietors in the county courts, then withdrew from participation with the execution in civil government. From that period the power of the bishops made rapid strides, insomuch that they have succeeded in retaining many branches of jurisdiction of which in other countries the temporal power has deprived them. In addition to the general canon law, we have in England a particular provincial law—the *constitutions* of the papal legates and councils of this country in 1237 and 1269; and a farther body of constitutions, framed in provincial synods under the authority of successive archbishops of Canterbury, from Stephen Langton in 1222 to Archbishop Chichele in 1414, and adopted subsequently by the province of York. These constitutions have been illustrated by the commentaries of distinguished ecclesiastics, and principally those of Lyndwood, who flourished in the reigns of Henry V. and VI. The canons of the Protestant church passed in the Convocation of A. D. 1603, although ratified by King James I. for himself and his successors, yet do not (as Lord Mansfield finally decided) bind the laity, except so far as they declare the older provisions of the law. The most standard work on English Ecclesiastical Law is *Gibson's Codex Juris Anglicani*. The best guides for the student are the treatise of Dr. Burn, and the recent one of Mr. Rogers (1840).

Law of England, Common Law.—This expression is used in two different senses, according to the subject under consideration. We speak of the common law in contradistinction to the civil law, or to equity; meaning a certain portion of our laws relating to a definite subject matter, and administered in courts following particular rules of evidence and modes of procedure. We also, by the common law, sometimes mean the unwritten or ancient customary law: in this sense it is opposed to the statute law, which is of positive enactment.

The constitution and laws of our Anglo-Saxon ancestors have been the subject of innumerable theories and contradictory systems, since the ingenuity of modern times has been applied to their investigation; but all the efforts of the learned have gone no farther than to establish the existence of a few principles and customs common, for the most part, to the Germanic tribes in general. The leaders of the Saxons emulated each other in assuming the kingly dignity in every district of the island, and endeavoured, as far as the independent spirit of their followers would allow, to adopt the imperial style and legislative powers which the British kings had derived from the provincial tyrants of the empire, and these from the Cæsars. The vanquished population lost its language and rights, and became bond to the invaders. These divided the land among them as partitioners equal in rights, on the system called *allodial*, or granted *benefices* to their dependents; and hence arose the principles of feudality. But for centuries England was one battle field, between the several clans of Saxons who had usurped her dominion: Mercia, Wessex, and Northumberland were divided in law and custom scarce less than in government; and when the island had at last fallen under the dominion of a prevailing Saxon dynasty, the invasion of the Danes again mixed and adulterated her blood and her institutions. Edward the Confessor reduced the customs of the country into something resembling a system of law; and although his enactments are lost, it is to his reign that we must look for the most authentic form of Saxon polity. The king was guided and controlled in his deliberations by the witan, or chief men, assembled in the gemote, or meeting; but their relative power and that of the sovereign varied according to the strength or weakness of the latter. The body of landholders held their lands by an independent tenure, which custom rather than law had rendered hereditary; but there were many who held benefices or enjoyed land under personal grants from the king, or from the great earls, who had succeeded the aldermen of the early Saxon times, or from the thanes or inferior nobility. Great part of the land was cultivated in common by the people of hamlets and tythings. Justice was administered in the county courts, where the *good men* or land owners assembled, and the bishop and sheriff presided. Questions of property were decided by ordeal, or by a tribunal of sworn witnesses. In criminal as well as civil cases the defendant sometimes freed himself by the oath of compurgators, or wager of law, as it was called when adopted by the Normans. The inhabitants of every district were mutual guarantees, by the custom of frankpledge, which was founded on two principles: the one, the liability of the lord or superior for the appearance of his vassals; the other, the collective responsibility of the tything, or hundred, for all its individual members: which was not prevalent in all England, and entirely unknown in the northern shires.

By the Norman conquest, and the division of the better portion of England between Norman proprietors holding in chief of the crown, the feudal system of law, as regarded land and its incidents, was early introduced into the country. Other portions of Norman jurisprudence were imported at a later period, through the medium of the king's courts; which, being at first confined in jurisdiction to the domains of the crown, gradually supplanted the old Saxon courts, although these long continued to be governed by their national law.

The three great institutions in which English law differs from that of other countries—the parliament; the system of tenures and their incidents, on which the law of real property is founded; and the trial by jury—may perhaps be said to have been founded on Norman jurisprudence, but to have become prevalent through their analogy to Saxon institutions. *See* PARLIAMENT.

The first consequence of the invasion of the Normans was, that different modes of trial were prevalent, according to the nation to which the contending parties belonged. Compurgation, or "wager of law," was the common mode of decision between Englishmen. In criminal cases, it was usually by the oath of eleven compurgators chosen out of an array of fourteen. In civil suits, the amount of the compurgation required seems to have been regulated by the value of the property claimed. To this peculiarly English mode of trial was added the *wager of battle*, which is first named in the laws of the Conqueror, but which either French or English and French might use. *Inquest of witnesses* was a Norman mode of trial in civil cases, by which witnesses were summoned from the neighbourhood in which the quarrel arose to declare on their oath the truth concerning the matter in question. Finally, the ancient proof of *ordeal* subsisted in criminal cases.

This diversity in the modes of trial was accompanied by a diversity of judicature. The ancient county courts received one blow by the withdrawal of the bishops, who ceased to preside in them, becoming chiefly foreigners, and who gradually established, as before shown, a separate jurisdiction of their own. A still more important wound, in its consequences, was inflicted by the increasing power and influence of the king's courts, at first only confined to causes arising within the royal demesne; in which the Norman law and modes of procedure were adopted, and in which the machine of our own common law was gradually elaborated by judicial ingenuity during successive centuries.

Henry the Second is commonly regarded as the founder of the common law. His principal contribution towards it consisted in his ordinance of the grand assize; justices in eyre, or circuit justices of the king's courts, being appointed to try causes by inquest of twenty-four witnesses, at the option of the tenant or demandant, if either party preferred to purchase this mode of trial instead of the ordinary trial by battle. Shortly after his reign the Fourth Council of Lateran, by abolishing the ordeal (A. D. 1215), gave a new impulse to the development of the jury system. Criminal cases were now tried by a jury of witnesses de vicineto; and the process by which these witnesses, both in civil and criminal cases, became con-

verted into sworn judges of the fact, has never been distinctly traced; but the intermediate steps had certainly all been passed before the reign of Edward III., possibly before the death of the first monarch of that name.

If Henry the Second was the founder, Edward I. may almost be regarded as the completer of the common law. From his time to the present no change has taken place in its general principles: all that subsequent reforms have effected has been to accommodate those principles to altered circumstances. And long may the spirit of these institutions remain unchanged amidst the march of improvement; — holding together, as they now do, the mightiest commercial community of the globe, with no less beneficial authority than they exercised six hundred years ago over the barons, peasants, and burghers of a small feudal monarchy!

The system of real property may be said to have been fixed by the statute *Quia Emptores*, 18 Edw. I. Before that time we may consider the lands of England as having been subject, in general, to the unrestricted feudal law. All land was held, mediately or immediately, of the king. The two classes of free proprietors were those who held by the military service (of Norman introduction), and those who held by the old Saxon custom. their property in their lands being retained by them, subject only to acknowledgment or fealty to the sovereign, — a less honourable, but probably a less burdensome tenure. But either of these tenants might, in his turn, create fresh tenants under him, yielding the same homage to him which he yielded to the sovereign. Below these, the only two classes of tenants recognized by the law were those who held of the king, or mesne lords, by pure villenage, or absolute and base service; and by villein socage, which was also a base service, but restricted to certain specified duties. From the tenure of pure villenage have sprung our present copyhold tenures; by which certain lands are held within *manors* (which are the old estates held in early times directly of the king) by the *will of the lord*, as it is expressed in their grant, although by long usage the will of the lord is merely nominal, and the obligations of the tenant consist only in certain specified rents and services.

The object of the statute *Quia Emptores* was to restrain the creation of fresh subordinate estates, by declaring that if any one alienated his land by sale or feoffment (which purported to convey it in perpetuity) the feoffee should hold the same, not of the feoffor, but of the feoffor's lord, whether a mesne lord or the king himself. Hence all manors must have existed prior to the reign of Edward the First; as it is essential that there should be in them tenants who hold of the lord, and such tenancies could not have been created at a later period.

When alienation of lands and tenements was made in early Norman times, the alienation was either to the donee and his heirs for ever — thus giving him an absolute unrestricted property, descendible to his heirs, whether male or female, subject only to his homage to the donor; in other words, a *fee-simple;* or it was upon condition — as, for instance, a grant to a donee, provided he had issue; under which grant, if the donee died without issue, or his issue came to fail, the land would revert to the donor. The conditional donees had devised, with the assistance of the king's judges, various ingenious methods of defeating these provisions; as by aliening as soon as they had issue, and then repurchasing the fee-simple. It was to fix the law of conditional gifts that the statute *De Donis*, 13 Edw. I., was passed; by which such a donee was absolutely prevented from aliening the tenements. Hence arose *estates in fee-tail:* in other words, estates granted to a man and to certain specified heirs; for example, the heirs male of his body. In after times, when the restraint on alienation which this statute created began to be repugnant to the more liberal feelings of the people, certain devices were invented (fines and recoveries), whereby the donee in tail was enabled to bar the entail and acquire the fee-simple, as he could have done before this statute was passed.

Besides these famous statutes, we find the reign of Edward I. distinguished by the confirmation of Magna Charta and the Charter of Forests. The first of these great constitutional acts contains few provisions of much importance in legal history, and was far more valuable as an evidence of the spirit of the country in restraining arbitrary usurpations, than, as is commonly supposed, by establishing any new franchises, or even confirming ancient ones. Perhaps its most important legal effect was the fixing to the city of Westminster the court of Common Pleas, which had formerly caused the suitors much inconvenience by following the person of the king in his numerous progresses.

It is also to Edward the First's reign that we must refer for the distinct definition of the province of that court, and of the other two superior common law courts of record, the King's Bench and Exchequer. The history of these three courts is far too intricate, and requires too much explanatory statement, to find a place in these pages. It must suffice to observe, that the King's Bench is the ancient Aula Regia, in which the king was supposed, as by fiction of law he still is, to sit in person, and which followed him in all his progresses, insomuch that in the reign of Edward I. it actually sate in Scotland. Its jurisdiction consequently extends to all matters which are of the king's prerogative: it took cognizance of criminal causes on the crown side, and of civil causes; at first those in the result of which the king was interested, and by a fiction all personal actions whatever. It was likewise a court of appeal from all inferior courts of records. The court of Common Pleas, or Common Bench, had in strictness jurisdiction in all civil causes between subject and subject. In this court only real actions, in which the right to land is tried—now nearly fallen into disuse (*see* PLEADING), but anciently the most important part of judicial business—could be adjudicated. The court of Exchequer was intended to recover the king's debts, and ordinary revenues of the crown. It acquired in process of time a jurisdiction over common personal actions, by the fiction of the complaining party being a debtor to the king; and also an equitable jurisdiction, similar in form to that of the chancellor's court.

The equitable jurisdiction of the chancellor had probably commenced long before the reign of Edward I. (*see* CHANCERY), and before his reign the original writs, by which actions were commenced, had been sued out or obtained in the chancery; the clerks of which, like the pontifical framers of the *actiones* among the Romans, had the monopoly of drawing up these magical instruments. In the reign of Edward I. (by *Statute of Westminster the Second*, 13 Edw. I.) an important change was made in this branch of law, by authorizing the clerks to frame writs adapted to particular cases which the old forms did not adequately suit. Hence originate our modern actions of *trespass on the case*. *See* PLEADING.

From the same statute the modern judges of *assize* and *nisi prius* (*see* NISI PRIUS) are chiefly derived. These were originally occasional commissioners, sent down into the counties to deliver the gaol of prisoners, or to try civil causes. By this statute the commission was first directed to be given to the king's justices, associated (as they still are in form) with one or two discreet knights of the county. The commission of assize is, strictly speaking, a commission to try disputes respecting land wherein the writ of assize (which dates, as before stated, from Henry II.) was brought, — now fallen into disuse. The commission of *nisi prius* originates in what may now be called a legal fiction. When the pleadings in an action in the superior courts (*see* PLEADING) are concluded, and an *issue of fact* is taken between the parties, the issue is appointed, by the entry on the *record* or written proceedings, to be tried by a jury from the county in which the proceedings arise at Westminster, *unless before* the day appointed (*nisi prius*) the judges shall have come to the county in question. Besides these commissions, the same judges try criminal cases by virtue of a *commission of the peace*, in which they are associated with the justices of the county; a commission of *oyer and terminer*, to hear and determine all treasons, felonies, and misdemeanors; and a commission of general gaol delivery, to try and deliver every prisoner who shall be in the gaol at their arrival in the county.

Having referred to the reign of Edward I. as the period under which a general sketch of our old common law might be most advantageously presented, we proceed to notice very briefly the chief alterations which mark its subsequent history. These alterations can be easily ascertained where they were caused by the highest legal authority, — by the parliament of the nation. But far greater changes have been wrought by the silent course of the tribunals, — by the discretionary power which our judges have assumed to extend the remedies, which they were authorized to administer, to cases unprovided for by earlier law, which either the ingenuity of practitioners, or, in many more instances, the increasing wants and more intricate relations of life had called into existence. To trace such alterations is as impossible as to note, day by day, the increase of stature by which the child grows into the man. Often, in laboriously investigating the history of our English jurisprudence, we are surprised when we look back, after perusing the events of a generation or a century, to the state of things as it existed at the beginning of that epoch, and find that although we cannot with all our diligence detect in its history the occurrence of any external changes in the subject on which our minds are fixed, yet the same forms, the same modes and circumstances, present themselves to our eyes under a totally different aspect and character.

The reigns of Henry II. and III. are principally remarkable for the gradual substitution of the king's justices of the peace for the various elective magistrates who exercised the several duties of that office before. It was in the reign of the latter prince also that the parliament is supposed to have finally acquired its present form. Under the successors of the Edwards, and during the wars of the fifteenth century, small accessions were made to the general bulk of English law; but during those

times very great changes were silently taking place in the disposition of property by means of the invention of Uses, borrowed from the civil law. This extensive and most important subject will be found briefly treated of under the head of CHANCERY.

The laws of Henry VII. had principally in view the benefit of his exchequer; and hence various more compendious modes of enforcing justice against delinquents who might be liable to fine date from his reign: methods which in unjust times were oppressive and arbitrary, although now useful instruments in the hands of justice. Such was the proceeding by information, instead of indictment, in various cases on behalf of the crown. The Statue of Fines, passed in this reign, confirmed and extended a mode already in use of barring entails. Under his successor, whose reign forms so important an epoch in political history, the laws of property were very considerably modified by the two statutes of Uses and of Wills. (For the former, *see* CHANCERY.) The latter rendered general the power of devising estates by will. The system of bankrupt laws also had its commencement under Henry VIII. His daughter Elizabeth did not add much to the essential and valuable parts of our statute book; but under her government the acts which restrained the alienation of lands by ecclesiastical bodies were passed, and also the celebrated statute respecting the poor, of which the policy forms, even at the present day, a subject of such ardent controversy. In the succeeding century, the reign of James I. witnessed the first attempt to limit the period at which actions and suits might be commenced; and the first statute of bankruptcy. But it is most remarkable for the laborious attempt to systematize our ancient law by Sir E. Coke, one of the most acute, if not philosophical jurists of any age or country. That of Charles II. forms the next marked epoch in the history of our law, after those of Edward I. and Henry VIII. His restoration was distinguished by the abolition of feudal tenures and incidents, and the reduction of all the modes by which estates of inheritance might be held (with few exceptions) to two only,—freehold and copyhold. The Statute of Frauds, a necessary protection perhaps to unwary transactors of business, but a source of endless litigation; the statute which regulates the distribution of the effects of intestates; and finally, the celebrated Habeas Corpus Act, which gave, or rather confirmed, to every person imprisoned by any authority short of the express and definite course of justice, the means of releasing himself,—are all productions of this reign.

The eighteenth century, while it gave rise to new views and widely extended discussions on jurisprudence, did not in England produce much substantial alteration by statutory enactment. It was rather a period of preparation for change, in the political as well as the legal world, than of actual reform. But it was distinguished by the learning and acuteness of several judges who occupied the seats of justice during many years, and introduced by the slow exertion of their own authority a new spirit into institutions of which the forms were preserved.

Recent years have introduced some material changes, of which the effect has not yet been fully tried. Lord Ellenborough and Lord Eldon had pursued the work of maintaining and embellishing the old institutions; succeeding judges have at last assumed in some degree the character of reformers. Sir Robert Peel's criminal statutes conferred a great benefit on the country, by removing many of the technical difficulties incident to this branch of law, although they did not materially affect its spirit; which, in the article of capital punishments, has been gradually moderated by a succession of enactments, from the beginning of the reign of George III. until that of our present sovereign. Many of the artificial distinctions, grounded on obsolete reasons, which subsisted between the practice of the different common law courts have been removed. The system of pleading (see that article) has been very materially changed. And in consequence of the general feeling in favour of local courts of justice to administer redress in trifling disputes between parties at a distance from London, some extension has been given to the authority of the sheriff's court, and some local tribunals have been constituted. Lastly, the ancient usage of imprisonment on mesne process has been abolished, and much additional power given in lieu of it to the Insolvent Court over the property of debtors.

The term Common Law is ordinarily employed in two different senses. In its legal signification it expresses the old unwritten law, established by precedent and custom; comprising, it has been said, " all recognized doctrines and customs, however introduced, which are neither to be found in the statute book, nor depend on the adjudication of courts of equity. For this floating mass of legal principles our ordinary sources are precedents, or decisions of common law judges, as contained in published reports. Where these fail us, reference may sometimes be had to more uncertain guides, the dicta of legal writers, or the general principle and tendency of our laws, for authority in deciding a particular dispute.

In its popular sense, common law is opposed to equity and ecclesiastical law; and thus comprises the whole of that law, both criminal and civil, which is administered in courts having trial by jury, and all the other subjects which are within the purview of the common law courts of Westminster Hall, and of the various local jurisdictions of the country (except so far as some of them exercise equitable authority). It has been defined " the whole of that code, whether founded on statute, usage, or precedent, which is now administered in the common law courts of Westminster Hall;" and this definition will comprehend the law administered in the various local courts in question, as these are bound to act on the decisions of the superior courts. Its peculiar characteristic is, that questions of fact arising out of its proceedings are submitted to the decision of a jury.

It is, perhaps, not very easy to assign either the history or the theoretical principles of the separation of equity from common law. The former was undoubtedly in the first instance a jurisdiction of a remedial character, intended to moderate, according to the conscience of the judge, the rigour of legal judgments; but this is a peculiarity which can scarcely be said to distinguish it in the present day. Its rules are as accurately laid down by precedents as those of the common law itself; but there are some subjects (as, trusts) which, having been created in frustration of the provisions of the common law, are out of its cognizance. Over these courts of equity have an *exclusive* jurisdiction. There are others over which both equity and law have *concurrent* jurisdiction. But the remedies applied by law to injuries committed are subject to certain inflexible rules. The power of a jury has limits from the very nature of the institution. It can award a debt sought to be recovered, or damages for an injury; but it cannot modify the remedy according to peculiar circumstances. Nor has it any means to enforce a course of action other than by imposing damages for neglecting it. To take a familiar instance:—If A. sues B. at law for breach of covenant, and judgment passes in favour of A., all that a jury can do is to award damages to A. for the breach of contract; but equity can, by a process of its own, compel B. to a specific performance of the contract under the penalties attached to a contempt of court. So, if one of several joint contractors be liable, at law, for penalties or debts incurred in respect of their joint undertaking, his only legal remedy is by an action against each; in equity, he can compel each of his partners to contribute to the extent of their liability.

LAW, MARITIME. *See* MARITIME LAW.

LAW, MARTIAL, is proclaimed by authority of parliament, on an emergency of rebellion, invasion, and insurrection. It is properly the putting under the cognizance of courts martial a great variety of subjects which by ordinary military law do not appertain to them, to be tried in a summary way. Where martial law is proclaimed all military persons, under all circumstances, are placed within its jurisdiction: even their debts are subject to inquiry before a military tribunal. It extends also to a variety of cases not relating to the discipline of the army, and offences committed by non-military persons, as plots against the sovereign, intelligence to the enemy, &c. The statute for putting into execution martial law usually gives a power to arrest and detain in custody all suspected persons, and to cause them to be brought to trial in a summary manner by courts martial, and to execute the sentence of all such courts, whether of death or otherwise; and declares, that no act done in consequence of these powers shall be questioned in any of the king's ordinary courts of law, and that all who act under the statute shall be responsible for their conduct only to such courts martial.

LAW, MILITARY, is properly that law which is administered by courts martial, under the authority of parliament and the Mutiny Act, annually passed, together with the Articles of Law. *See* COURTS MARTIAL.

LAWN. (Fr. linon.) A fine variety of cambric, formerly exclusively manufactured in Flanders. Of late the lawn manufacture of Scotland and of the north of Ireland has been brought to rival that of the Flemish weavers.

LAWN. In Gardening, a surface of grass or turf in pleasure grounds kept smoothly mown.

LA'XATIVE (Lat. laxare, *to loosen*), a gentle aperient medicine: opposed to *cathartics*, which are drastic purgatives.

LAY. (Probably the same word with the German lied, *song*.) The lyric poems of the old French minstrels, or trouvères, were termed lais; but the title appears, in modern usage, to be peculiarly appropriate to narrative poems, or serious subjects of moderate length in simple style and light metre.

LAY. In Agriculture. *See* LEA.

LAY BROTHERS. Persons received into convents of monks, under the three vows, but not in holy orders. The introduction of this class of devotees appears to have begun in the 11th century. They are dressed somewhat differently from the other monks or *brothers of the choir*, and often employed in the manual exercises necessary for

the uses of the community. The Carthusian and Cistercian orders are said to have first recognized the distinction, and their example was followed by the other orders. The same distinction exists in monasteries of females between the nuns properly so called and the lay-sisters, or sisters converse.

LAY ELDERS. In Presbyterian churches, ministers of ecclesiastical jurisdiction, not ordained as clergymen, who assist the pastor in each congregation. (*See* PRESBYTERIANS, KIRK.) The divines of that persuasion rest the appointment of lay elders in some measure on that of presbyters "in every city," by Paul and Barnabas, who, they imagine, from the manner in which they are mentioned, could not have been all preachers. (See *Hooker, Eccl. Pol.* b. vi.)

LAYERS. In Gardening, a mode of propagating plants by laying down shoots, and covering a portion of them with soil, so that the extremity of the shoot is left above ground, and the shoot itself not detached from the plant. In order to facilitate the rooting of such layers, the portion of the shoot buried in the soil is fractured by twisting or bruising, or cut with a knife immediately under a bud. This operation, by obstructing the return of the sap from the leaves, occasions its accumulation at the wounded part, when roots are there produced from the effort of nature to perpetuate life.

LAY'ING. In Architecture, the first coat on lath of plasterer's two-coat work, the surface whereof is roughed by sweeping it with a broom; the difference between laying and *rendering* being that the latter is the first coat upon brick.

LAYMAN. (Gr. λαϊκος; from λαος, *people*.) The appellation by which the rest of the community are distinguished from the clergy. (*See* LAITY.)—*Layman*, or *lay-figure*, among painters, signifies a small statue, whose joints are so formed that it may be put into any attitude for the purpose of adjusting the drapery of figures.

LA'ZAR-HOUSE, or LAZARETTO. (Ital.) A public building in the southern European states, of the nature of an hospital, for the reception of the poor and and those afflicted with contagious disorders. In some places lazarettos are set apart for the performance of quarantine; in which case only those are admitted who have arrived from countries infested by the plague, or suspected of being so. Howard's well-known account of the principal lazarettos of Europe furnishes the most detailed and interesting particulars of these establishments, and to it we refer the reader for full information.

LA'ZARISTS. In Ecclesiastical History, a body of missionaries founded by St. Vincent de Paule in 1632; so termed from occupying the priory of St. Lazarus, at Paris, as their head quarters. Their primary object was to dispense religious instruction and assistance among the poorer inhabitants of the rural districts of France. They were dispersed at the time of the Revolution, but have since re-established a congregation at Paris; and the French government has lately projected entrusting them with the spiritual care of the colony at Algiers.

LA'ZARUS, SAINT, ORDER OF. A military order of religious persons, originally an association of knights, for the purpose of maintaining lepers, &c. in lazar-houses or hospitals, especially in the Holy Land. Being driven out of Palestine in 1253, they followed St. Louis to France. In 1490, their order was suppressed by Pope Innocent VIII., and united with that of St. John; but the bull was not universally received. In 1572, they were united in Italy with the order of St. Maurice; in 1608, in France, with that of Our Lady of Mount Carmel. The knights of these united orders were allowed to marry.

LA'ZULITE. A blue mineral from Styria and the Tyrol, composed of 66 alumina, 10 silica, 18 magnesia, 2 lime, 3 oxide of iron.

LAZZARO'NI. A name given to the poorer classes at Naples, from the Hospital of St. Lazarus, which served as a refuge for the destitute in that city. Forty years ago two large sections of the people were generally comprehended under this name — the fishermen; and the lazzaroni, properly so called, who lived in the streets, and performed no other labour but that of errand porters and occasional servants. These alone were estimated at 40,000. These Lazzaroni formed a powerful community, which under Masaniello accomplished the revolution of Naples; and, in later times, overthrew the popular government, under the influence of Cardinal Ruffo and the English party. But during the French occupation of Naples they ceased to exist as a distinct class; and the name is now only used to designate in general language the mob or populace of that great city.

LEA, in Agriculture, is a term applied to lands which are kept under grass or pasturage for a short period. For example, in a rotation of fallow, wheat, clover, and rye grass, for three years. The ground, when under clover and rye grass, is said to be in lea, in Scotland; or in England, in lay.

LEAD. A metal of a bluish-grey colour. Its specific gravity is 11·38. It is very soft, flexible, and inelastic; and though ductile and malleable, is possessed of very little tenacity. It fuses at about 600°; and if air be carefully excluded, it does not appear to be volatile at a white heat. When melted in open vessels, it soon changes into a grey powder, which upon further exposure to heat and air becomes yellow, and is called *massicot;* or, when partially fused, so as to assume a scaly form, *litharge*. If massicot be heated, and stirred to prevent fusion, it gradually absorbs oxygen, acquires a red colour, and is called *red lead*. When red lead is heated in nitric acid, it is partially dissolved, and partly converted into a brown powder, which is insoluble, and is a *peroxide of lead*. Massicot, or the yellow oxide of lead, is the *protoxide*, and that which forms the salts of this metal: it is constituted of 1 atom of lead = 104, and 1 of oxygen = 8, and its equivalent is 112. The brown peroxide consists of 1 atom of lead and 2 of oxygen; and red lead is intermediate between the two extremes, consisting, probably, of an indefinite mixture of the two oxides. The protoxide of lead is soluble in the greater number of the acids, and forms a variety of salts; of these the carbonate and the acetate are the most important. *Carbonate of lead*, or, as it is commonly called, *white lead*, is the basis of white oil paint, and consequently of a number of other colours: it may be prepared by exposing sheet lead to the fumes of vinegar, by which it is gradually corroded, and its surface becomes covered with an incrustation, which, when scraped off and well levigated, is white lead. This article is also made by precipitating a solution of acetate of lead by carbonate of soda; it consists of 112 oxide of lead and 22 carbonic acid. *Acetate of lead* is made by dissolving carbonate of lead in acetic acid, for which purpose the pyroligneous vinegar is chiefly used. It crystallizes in six-sided prisms, but is generally met with in confused crystalline masses. It is soluble in about 4 parts of cold water, and the solution has a remarkably sweet taste; whence the term *sugar of lead*, usually applied to this salt. It consists of 112 oxide of lead and 51 acetic acid. The crystals include 3 atoms of water, and are therefore represented by the equivalent 190; or 163 dry acetate and 27 water. When protoxide of lead is boiled in distilled vinegar, or in a solution of acetate of lead, a dense solution of subacetate or *triacetate* of lead is obtained: it is difficultly crystallizable. This solution is often used in the chemical laboratory as a test and precipitant: and it forms the *extract of lead*, or *Goulard's extract* of pharmacy.

The most important native combination, or *ore of lead*, is the *sulphuret*, composed of 104 lead and 16 sulphur. It is the *galena* of mineralogists, and from it the commercial demands for lead are supplied: it is roasted to expel sulphur, and the lead thus oxidized is reduced by heating with charcoal. The action of water upon lead is curious and interesting, in consequence of the universal use of cisterns lined with this metal. Perfectly pure water, such as distilled water, put into a clean leaden vessel and exposed to air, soon oxidizes and corrodes it, and delicate tests discover oxide of lead *in solution* in the water; but river and spring water exert no such solvent power: the carbonates and sulphates in such water, though in very minute quantities, entirely prevent its solvent power. Hence it is that leaden cisterns are used with impunity for the preservation of common water, and that the crust which forms upon the metal effectually prevents all further action. As this crust partly consists of carbonate of lead, which is very poisonous, great care should be taken to prevent its diffusion through the water upon any occasion, as by scraping or cleaning the cistern. There is another way in which leaden cisterns sometimes prove injurious; and that is in consequence of galvanic action, where iron or zinc pipes are soldered or let into them: the lead is thus rendered electro-negative, alkaline matter is evolved upon it, and small quantities of the oxide or carbonate are thus rendered soluble. There are several re-agents by which very minute quantities of lead may be detected; among these, solution of sulphuretted hydrogen is perhaps the most effective: it produces a brown tint in water containing the minutest trace of lead, and it similarly discolours the greater number of the insoluble salts of the metal. A solution of sulphate of soda is also a sensible test of the presence of dissolved oxide of lead; it forms a white cloud in water containing the smallest traces of it: a fragment of iodide of potassium dropped into such water presently occasions in it a yellow tint, in consequence of the formation of an iodide of lead.

LEAD, BLACK. *See* PLUMBAGO.

LEAD, for Sounding. The common hand lead weighs 11 lbs. with about 20 fathoms of line. The leadsman stands somewhere on the side of the vessel, leaning against a band for the purpose: lets the lead descend near the water; then, swinging it over his head once, or twice if the ship is going fast, throws it forward. The line is marked at 5, 7, 10, 13, 17, and 20 fathoms. The numbers between are called *deeps;* thus, "by the mark 7," "by the deep nine," indicate 7 and 9 fathoms.

When the depth is great, the deep-sea lead of 28 lbs. is used. The lead is dropped from the fore part of the vessel, the line being passed outside all. It is generally necessary to heave the ship to.

LEADING NOTE. In Music, the sharp seventh of the scale.

LEADS, or SPACE LINES, are pieces of type metal cast to specific thicknesses and lengths, lower than types, so that they do not make any impression in printing, but leave a white space where placed. Their general use is to be placed between the lines when a work is not closely printed, which is considered to look better than when printed solid, and also to branch out the heads of pages and titles.

LEAF. (Sax.) An expansion of the bark at the base of a leaf-bud, prior to which it is developed; its function being at once that of respiration, digestion, and nutrition. It is a plate of parenchyma, through which spiral vessels and woody tissue ramify. Its surface is covered with stomates, which communicate with minute hollow chambers in the interior. It is in the leaf that all the peculiar secretions of a plant are prepared out of the under sap which the roots obtain from the soil.

LEAF-BUDS. Rudiments of young branches, made up of scales imbricated over each other, the outermost being the hardest and thickest, and surrounding a minute axis, which is in direct communication with the woody and cellular tissue of the stem. When stimulated by light and heat they extend into branches; or if artificially removed from the plant that bears them, they are capable of multiplying the individual from which they have been taken.

LEA'FLET. A small leaf formed by the petiole of a leaf branching out, and separating the cellular tissue of the lamina into more than one distinct portion, each of which forms a perfect lamina of itself.

LEAGUE. A measure of length, used in reckoning distances by sea. The sea league is three nautical or geographical miles, or the 1-20th of a degree, and consequently about 3·45 English miles.

The common land league is a well-known itinerary measure on the continent of Europe, chiefly in France. The French, however, have two distinct leagues: the legal posting league (*lieue de poste*), containing 2000 toises, and equal to 2·42 English miles; and a league of 25 to the degree (anciently the *lieue moyenne*), or equal to about 2·76 English miles. This last, however, can scarcely be regarded as a definite measure; and previous to the Revolution the league was different in the different provinces. The word is said to be derived from the Celtic leach, *stone;* the distances having been marked by stones in the Roman provinces. In Gaul alone of those provinces, they were marked in some instances by leagues as well as miles. The Gaulish league was considered by the Romans as equal to a mile and a half of their own measure, or as containing 1500 Roman paces. It is supposed that the league, or *leuca*, was introduced into England by the Normans, where, at an early period, it came to be reckoned as equivalent to two miles of the time; this being the sense in which the term *leuca* is used by the oldest law writers, and in most of the old English charters. *See* MILE.

LEAGUE, in Politics, appears to be in strictness an alliance between two or more powers, in order to execute some common enterprise. It is therefore more active, and less durable, than an alliance or a confederacy; both of which have some permanent object, while neither necessarily requires active co-operation. In the middle ages, the word league was used nearly in the sense now attached to these latter terms: hence we read of the Hanseatic league, and of the three leagues still subsisting in the canton of the Grisons in Switzerland; both of which were more properly confederacies. The word is of Spanish origin; and it has been said that the period of its commonest use in political language was commensurate with that during which the Spanish government exercised the greatest influence among those of Europe, — the 16th and 17th centuries.

LEAGUE, SOLEMN. *See* COVENANT.

LEAGUE, THE HOLY, or simply THE LEAGUE. In French History, a political association formed by the Roman Catholic party in France under the reign of Henry III. The project of the League is said to have been framed by one David, an advocate; or, rather, he first conceived the idea of uniting the separate associations of the Catholic party in the provinces into one great confederacy. His written scheme bears date 1575. It was ardently received, especially by the municipality and citizens of Paris and other large towns. The object of the League was at first only the overthrow of the Protestant power; but the princes of the house of Guise soon placed themselves at its head, and the leaders of the party were not slow in adopting the project of changing the succession, and placing the Duke of Guise on the throne. In 1588, the citizens, under the impulse of the League, drove Henry III. from Paris on the day of the Barricades, and formed the revolutionary government of "the Sixteen." But after the death both of the duke and the king, much division arose in the head quarters of the League at Paris as to the choice of a successor; and in 1591 the popular party, or that of the Sixteen, was put down by the citizens: which event in effect destroyed the power of this great association, although it still continued to exist, even after the abjuration of Henry IV.

LEAKAGE. In Commerce, an allowance in the customs, granted to importers of wine for the waste and damage the goods are supposed to receive by keeping.

LEA'NTO. (Span.) In Architecture, a building whose rafters pitch against or lean on another building.

LEAP-YEAR, or BISSEXTILE. A year containing 366 days. In the Gregorian calendar this occurs every fourth year, excepting years which complete centuries; in which case the intercalary day is omitted, unless the number of the year is divisible by four. The term is probably derived from the *leap* or start occasioned by the insertion of the intercalary day, and would have been more appropriate if the year had been deficient by a day instead of being redundant. *See* CALENDAR.

LEASE, in Law, is properly a conveyance of lands and tenements (usually in consideration of rent or other annual recompence), made for life, for years, or at will, but always for a less time than the lessor or party letting has in the premises. The usual words of operation are, "demise, grant, and to farm let." The conveyance by a lessee of part of his interest is properly an under-lease; of the whole, an assignment.

LEASE AND RELEASE. In Law, a mode of conveyance appropriate to estates of freehold in lands, tenements, or hereditaments. Before the Statute of Uses, 27 H. 8. c. 10., it was customary to give lands to one person for the use of another; or to devise the use of land to one party, while the common law right to the same land descended to another. In a court of equity the legal owner of the fee was compelled to cede to the *cestuy que use*, or proprietor of the use, the enjoyment of the land; and certain modes of conveyance were employed by which the use was conveyed independent of the legal estate. By that statute uses were declared to be executed; *i. e.* that if land were conveyed to one party to the use of another, the *cestuy que use* became seised of the legal estate. Hence a *bargain and sale*—*i. e.* a deed in which for a recited pecuniary sum, technically called a *consideration*, land was conveyed to A. to the use of himself or of D.—became a good conveyance; because the deed gave the use, and the statute immediately added the legal estate. To prevent secret conveyances it was consequently enacted, in the same reign, that no estate of inheritance or freehold should be conveyed by bargain and sale, unless the deed was enrolled or registered in a certain specified manner. But as this statute did not extend to bargains and sales for a less estate than of freehold, the ingenuity of lawyers soon devised a new method of secret conveyance: the land was made over to the purchaser by bargain and sale for a year, and then the purchaser received a release of all the vendor's remaining interest. Thus, by these two deeds (which are now ordinarily comprised in one), a perfect conveyance is created, which has almost superseded, in general use, the older and more solemn modes of alienation for estates in fee-simple.

LEA'THER. (Germ. leder.) The prepared skins of animals. The principal object of the art of converting skin into leather is to render it strong and tough, durable, and often water-proof, and to prevent its destruction by putrefaction. The skins are first cleansed of hair and cuticle, and then impregnated either with vegetable tan and extract, as in the production of what is called *tanned* leather, or with alum and other salts, as for *tawed* leather: these processes are sometimes combined, and tanned leather often undergoes the further operation of *currying*, or impregnation with oil. As instances of these different results, thick sole leather is tanned; white kid for gloves is tawed; the upper leather for boots and shoes is tanned and curried; and fine Turkey leather is tawed, and afterwards slightly tanned.

Tanned Leather.—For thin skins which are afterwards curried, the hide is cleansed, and soaked for a day or two in water; it is then *beamed*, or stretched upon a solid half cylinder of stone, where it is cleared of adhering fat and flesh; it is then soaked for several days in a pit of lime and water, by which the hair and cuticle are so far loosened as to admit of being scraped off upon the beam; the hide is then washed and put into the *mastering* pit, which is a mixture of water and dung, — that of hens, pigeons, or dogs is preferred, cow or horse dung not being sufficiently putrescible. When the hide has here become soft and supple, it is again thoroughly cleaned, and submitted to the tanning liquor, which is at first used very weak, and gradually strengthened till the operation is complete: this requires from two to four months for calf skins, and from twelve to eighteen months for thick ox and boar hides intended for strong sole leather; and the latter hides, instead of being limed and dunged, are generally, after having been cleaned in water, placed in heaps, where they begin to putrefy, and then the hair may be removed without lime, which would be apt to render the skin hard and harsh. The further opening of the texture, so as to prepare it for tanning, is effected by immersion in a sour liquor of fermented rye or barley, or in weak sulphuric acid.

The process is called *raising*, and immediately precedes the tanning. When fully tanned, the goods are drained, stretched upon a convex piece of wood called a *horse*, and beaten and smoothed; or the leather is sometimes passed between cylinders to make it more solid and supple: it is lastly dried, by suspension in an airy covered building. It will be obvious (*see* TAN and GELATINE) that the principal change effected in this process depends upon the combination of the gelatine of the skin with the tanning of the oak bark, or other astringent material which is used, and that great care is requisite to ensure the perfect penetration of the hide (especially where it is thick) by the tanning material: hence the necessity of using weak liquors at first, and gradually increasing their strength; for if the hide were in the first instance put into a strong infusion of bark, the exterior surfaces would become so perfectly tanned as to be impervious to the further action of the liquor, and the centre would remain untanned, and consequently soluble and putrescible; so that we judge of the completion of the process by the leather, when cut through, being of a uniform brown throughout, anything like a white streak in the centre announcing the imperfection just mentioned.

Tawed Leather, &c.—The skins are first soaked, scraped, and hung in a warm room till they begin to exhale an ammoniacal odour and the wool readily pulls off; they are then scraped and soaked for some weeks in lime water, which checks the putrefaction and hardens the texture; the skin is then again beamed, smoothed, and trimmed, and put into a vat of bran and water, where it is kept for some weeks in a state of gentle fermentation, and becomes thin and extensible, and fit for any subsequent operation: in this state it is called a *pelt*. The method of bringing kid and goat skin to the state of pelt is nearly the same as for lamb skin, except that liming is used before the hair is taken off, which is only sold to plasterers, whereas lambs' wool is more valuable, and would be injured by the lime. If the pelts are to be tawed, they are worked about in a solution of alum and salt in warm water, which again makes them thick and tough; they are then washed, and again fermented in bran and water till the thickening is reduced by the removal of some of the salts; lastly, they are stretched on hooks, and dried in a stove room, when they become a tough flexible white leather; but to give them gloss and suppleness they are again soaked in water, and trodden in a large pail containing the yolks of eggs beat up with water; they are then dried in a loft, and smoothed with a warm iron.

Morocco leather, as it is called, is chiefly prepared from sheep skins, which, after the action of lime water, are brought down by a dung bath, and reduced to the state of pelt. If intended to be dyed red, they are sewn up in the form of a sack, with the grain side outward, and immersed in a warm cochineal bath; the sac is then tanned in a bath of sumach: the skins intended to be blacked are sumached without any previous dyeing. The graining and polishing are effected as follows:—The skins are stretched upon a smooth inclined board, and rubbed over with a little oil to supple them. Those intended for black leather are previously brushed over with a solution of iron; they are then rubbed over with a glass ball cut into a polygonal surface, which polishes them, and makes them firm and compact; lastly, the grained surface is given by rubbing the leather with a grooved boxwood ball. *Curried leather* is tanned, and then softened by soaking in water and rubbing; it is then pared with a broad sharp knife, rubbed with a polished stone, and while still wet besmeared with fish oil, or a mixture of this with tallow. As it dries the oil gradually penetrates in proportion as the moisture evaporates. The grain side is blackened by iron liquor, but the flesh side with lampblack and oil.

Shammoy leather is generally sheep or doe skin, prepared as already mentioned by dressing, liming, &c., and dyed if necessary, and then finished in oil. *Russia leather* acquires its peculiar odour from birch tar. (There is an excellent abstract of the manufacture of different kinds of leather in *Aikin's Dictionary of Chemistry*, from which the above is chiefly abridged.)

The leather manufacture of Great Britain is of very great importance, being inferior in point of value and extent only to those of cotton, wool, and iron. "If we look abroad," says Dr. Campbell, "on the instruments of husbandry, on the implements used in most mechanic trades, on the structure of a multitude of engines and machines; or if we contemplate at home the necessary parts of our clothing,—breeches, shoes, boots, gloves,—or the furniture of our houses, the books on our shelves, the harness of our horses, or even the substance of our carriages; what do we see but instances of human industry exerted upon leather? What an aptitude has this single material in a variety of circumstances for the relief of our necessities, and supplying conveniences in every state and stage of life? Without it, or even without it in the plenty we have it, to what difficulties should we be exposed?" (*Polit. State of Great Britain*, xi. 176.) The number of persons engaged in all the various branches of the leather manufacture in Great Britain is estimated at between 200,000 and 300,000, the total quantity of all sorts of leather at 65,000,000 lbs., and the entire value of the manufacture at 13,500,000*l*. Leather was long subject to a duty, which necessarily placed the manufacture under the surveillance of the excise; but it was totally abolished in 1830; and as the manufacture is now relieved from every sort of trammel and restraint, its rapid increase may be confidently expected. (See *Commercial Dictionary*.)

LEAVEN. (Lat. levare, *to raise*.) A piece of sour dough used to ferment and render light a much greater quantity of dough or paste. By the law of Moses leaven was strictly forbidden during the Passover; and the Jews, taught to regard it from the vigil of the feast as unclean, with religious scrupulosity purified their houses from the contaminating influence. In its figurative sense, *leaven* is applied to any thing that powerfully but gradually deteriorates the qualities of the mind or heart; in contradistinction to the expression *unleavened*, which implies the qualities of sincerity and truth.

LEAVES. (Sax. læaꝼ.) In Architecture, ornaments imitated from natural leaves; whereof the ancients used two sorts, natural and imaginary. The former were those of the laurel, palm, acanthus, and olive; but in the representation of all of them they took great liberties.

LECTI'CA. (Lat.) A sort of couch used by the Romans for the same purpose as the sedan chair, or rather the palanquin, is employed by the moderns; with this difference, that the person carried on the lectica reclined. It was used also for the conveyance of dead bodies to the funeral pile. The persons who carried the lectica were called *lecticarii*, whose number in the Lower Empire is said to have amounted to 11,000.

LE'CTISTE'RNIUM. (Lat. lectus, *a couch*, and sternere, *to prepare*.) A religious festival or ceremony among the ancient Romans, celebrated during times of public calamity, and remarkable as a singular relic of barbarous superstition, retaining the impression of a very rude age. In this festival the gods themselves were invited to the entertainment; their statues were taken from their pedestals, laid on couches with pillows and pedestals, and placed at the table, while the servants used gravely to convey the viands to the idols' lips. The first festival of this sort, according to Livy, which took place, was held in the year of Rome 354, on the occasion of a contagious disease which committed frightful ravages among their cattle and lasted for eight successive days. On the celebration of this festival enemies were said to forget their animosity, and all prisoners were liberated.

LE'CTOR. In the early Church, a person set apart for the purpose of reading parts of the Bible and other writings of a religious character to the people. They were consecrated by prayers and ceremonies for this office, and in the third century appear to have formed proper officers of the church. It is probably from this institution that the order of preachers in parish churches in England called *lecturers* is derived, who hold a distinct office from the vicar, rector, or other ecclesiastical functionaries; they are chosen by the vestry or chief inhabitants of the parish, supported by voluntary subscriptions and legacies, and usually officiate on Sunday afternoon.

LE'CTURE (Lat. lego, *I read*), signifies generally a discourse *read*, as the derivation of the word implies, by a professor to his pupils; but it is applied in a more extended sense to every species of instruction communicated *vivâ voce*. In the Scotch and Continental universities, as well as in those recently established in England, the great business of teaching is carried on by means of public lectures, delivered at stated periods, and embracing every subject included in the curriculum of study; but at the two great English universities, as is well known, a different system is adopted. There the established mode of instruction is by private tutors; and though a few lectureships have, from time to time, been founded, and lectures are sometimes voluntarily given by active members, still these are rather to be considered as incidental appendages than as constituent parts of a regular system.

Public lectures have been adopted from the earliest ages as a convenient mode of teaching the elements of every branch of human knowledge; and it is perhaps true that if they be properly compiled, and accompanied by strict and regular examinations, few means seem better calculated to awaken the attention of the student, to abridge his labours, to guide his inquiries, and to impress upon his recollection the first principles of science. The endless diversity of subjects on which lectures have been or may be given precludes, of course, any attempt to lay down rules applicable in all cases for the guidance of individual lecturers; but there are, notwithstanding, some great leading principles that should in every case be kept steadily in view. First of all, it should be borne in mind that, a lecture being an oral discourse, if the meaning of the lecturer be at any time mistaken or not perceived, the student or hearer

cannot return, as he would do to a book, for farther explanations, and the subsequent part of the lecture may in consequence be rendered nearly useless. Hence *perspicuity of statement* is the first and highest quality of a lecturer. Perspicuity, indeed, is indispensable to all good writing and speaking; but in lecturing especially it is the one thing needful, and without it other qualities can avail little or nothing. To attain this essential quality the subjects of the lecture should be so arranged that they may follow each other naturally and easily; the sentences should be clear and distinct, neither too long nor too short; the illustrations should be apposite, and of a kind fitted to excite and keep awake the attention of the hearer; and the lecture so composed should be delivered in a plain, distinct, and impressive manner. If a lecturer be deficient in these qualities, he can be of little or no use as a teacher, how well soever he may be acquainted with the subject on which he prelects. Dr. Brown, of Edinburgh, is an instance in point. his views with respect to the philosophy of the mind are often original, sometimes just, and always ingenious; but the style in which they are expounded is as bad as possible, even in a book made for the closet, and rendered his lectures all but unintelligible to nine tenths of his students. It has been the fashion among certain parties who certainly do not owe much to the *belles lettres* to depreciate the lectures of Dr. Blair; but they may be safely referred to as all but perfect models of the style and manner in which lectures should be written.

When lectures are prepared in the way now stated by parties well versed in the subjects prelected upon, and when they are regularly followed up next day by a searching examination of the students on the various subjects treated of, and explanations are given of such difficulties as may have occurred to them, they may, perhaps, as already stated, be regarded as a pretty unexceptionable method of teaching. But lectures got up, as they generally are, not to instruct the hearer, but to exhibit the attainments or prejudices of the lecturer, and unaccompanied either by examinations or exercises, are about the least profitable exhibitions at which a student can be present.

LE'DGER. *See* Book-keeping.

LEDGER-LINE. (Dutch, leggen, *to lie.*) In Music, a line either above or below the staff, when that is not sufficient in extent to lay the notes upon. It is above the staff in ascending progressions, and in descending progressions below it.

LE'DGERS. (Fr.) In Architecture, horizontal pieces of timber used in scaffolding, lying parallel to the wall opposite to which they are erected.

LEE, LEEWARD. Sea terms, denoting generally the side or quarter not directly exposed to the wind. The *lee-side* of a ship is the opposite to that on which the wind blows when it crosses her course, and which is termed the *weather side. Leeward* is on the *lee-side;* opposed to *windward*, or on the *weather side*. A *lee-shore* is the shore on the *lee-side* of the ship, or the shore on which the wind blows; and a ship is said to be under the *lee* of the shore when the wind blows from the shore, or when she is in some measure sheltered by the shore. The names Leeward and Windward, as applied to the West India Islands, were given to them from their situation in a voyage from the ports of Spain to Carthagena or Portobello. The islands which lie to leeward extend from Portorico to Demerara.

LEE-BOARD. A small platform of planks, which being let down into the water on the lee side of flat-bottomed vessels, opposes the action of the wind to drive them to leeward.

LEECH. This name is given to those abranchiate red-blooded worms, or anellidans, which are provided with a sucker at both ends of the body (*see* Hirudo), and of which we possess a few native species; some frequenting the fresh waters, as the horse leeches (*Hæmopis sanguisorba* and *H. stagnorum*); others the ocean, where they are parasitic upon fishes, as the skate-sucker (*Pontobdella muricata*). The medicinal leech (*Sanguisuga medicinalis*) belongs to that subdivision of the family *Hirudinidæ* which is characterized by having the superior lip of the anterior cup or sucker divided into several segments, and the oral aperture transverse, triradiate, and surrounded by three cartilaginous jaws, each armed with two rows of very fine teeth. This apparatus enables the leech to penetrate the skin so as to ensure a ready flow without causing a dangerous wound. The upper lip is marked with ten small points considered as eyes. The species of the genus *Sanguisuga*, viz. *S. officinalis* and *S. medicinalis*, are most common in the south of France, whence great numbers are exported to this country. The leech-dealers of Bretagne drive horses and cows into the ponds, that the leeches may fatten and propagate more abundantly by sucking their blood. Children are employed to catch them by the hand; and the grown persons wade into the shallow waters in the spring of the year, and catch the leeches that adhere to their naked legs. They are also taken by a sort of net made of twigs and rushes, which is used in the summer when the leeches retire into the deeper waters.

The best method of preserving these valuable little animals is stated by the author of the article "Leech" in the *Penny Cyclopædia* to be that described by Fee. It is as follows: —

Into a marble or stone trough a layer of seven inches of a mixture of moss, turf, and charcoal is to be put, and some small pebbles placed above it; at one extremity of the trough, and midway between the bottom and the top, place a thin plate of marble pierced with numerous small holes, upon which there should rest a stratum of moss, or portions of the *Equisetum palustre*, or horse-tail, firmly compressed by a layer of pebbles. The trough to be filled with water only so high that the moss and pebbles should be but slightly moistened. A cloth is to be kept over the mouth of the trough. This is imitating as nearly as possible their natural condition; and the charcoal not only aids in keeping the water sweet, but appears to prevent the leeches being attacked by parasitic animals, to which they are very liable. The water should be changed about once a week, and more frequently in warm weather.

The great importance of ascertaining the best method of preserving the medicinal leech may be inferred from the extent to which the trade is carried on, and the consequent increasing scarcity of these indispensable adjuncts to medicine. Four only of the principal dealers in London import 7,200,000 annually.

LEE'LITE. A pink silico-aluminous mineral tinged by oxide of manganese. Named from Mr. Lee of Cambridge.

LEET. (Sax. leod; Germ. leute, *people.*) The court leet, or view of frankpledge, was an ancient Saxon institution answering a double purpose: 1. The administration of justice in the trial of offences and the abatement of nuisances; 2. The preservation of the peace, and the prevention of crime, by the reception and enrolment of the pledge which each man was obliged to give by becoming a member of some tything. The possession of a court leet was the characteristic of the hundred, of which the proper leet was distinct from, and subordinate to, that which was held by the sheriff on his tourn. The court leet of the hundred was usually held by a bailiff or steward of the sheriff; but it was sometimes granted, as well as the leet of a smaller jurisdiction, to private lords. A court leet also properly belonged to a borough, which ranked as a hundred; but such private and borough leets were, like the leet of the hundred, subordinate to the county leet of the tourn.

LEE-WAY, in Navigation, is the deviation of the course actually run by a ship from the course steered upon; or it is the angle formed between the line of the ship's keel and the line which she actually describes through the water. In consequence of the action of the wind or currents, a ship is generally impelled *sideways* as well as forward, whence the direction of her motion is different from that of the keel. Suppose the whole force urging the ship to be resolved into two, — one producing the motion A B in the direction of the keel, and the other the motion A C in the same time at right angles to the former;

then the ship will move in the direction of the diagonal A D, and the angle D A B is the *lee-way*. To obviate the effects of this lateral motion, the ship is laid on a course to the windward of the point to which she is bound.

LEGACY. *See* Wills. (Lat. lego, *I bequeath.*) A gift by will of personal property, as goods and chattels; a testamentary gift of real property being called a devise. Legacies are general, such as a gift of a sum of money out of the general estate of the deceased; or specific, as a gift of a particular bank note or coin, or of any other individual chattel, as a horse or a jewel; or residuary, as a gift of the residue of the estate remaining after all the debts of the deceased and general and specific legacies have been satisfied. General legacies are subject to an equal rateable abatement, if the estate is not sufficient for payment of them in full; but a specific legacy is not subject to abatement, unless it be necessary for the payment of debts. A specific legacy is, however, subject to what is called ademption, which is the consequence of the subject matter of the legacy being one identical thing in specie: thus, if a testator bequeath a particular horse, which he afterwards disposes of in his lifetime, the legacy is said to be adeemed, or taken away, because the horse bequeathed has no longer any existence as part of his property, and the legatee will not be entitled to another horse of the testator's in lieu of it. This identity of corpus is so inherent in the notion of a specific legacy, that if a 100*l*. in Consols were bequeathed, and the same sum were afterwards transferred by the testator to another stock, the transfer of itself would adeem the legacy. The mode of compelling executors to pay a legacy is by suit in equity for the administration of the testator's assets: courts of law have not, in general, any jurisdiction over such mat-

ters. Executors cannot be compelled to pay a legacy until the expiration of a year after the testator's death: they are allowed that period for ascertaining and discharging his debts; and even after a legacy has been paid the legatee must refund, if it should be necessary, for the payment of creditors who come in, although after the period above mentioned. The party to whom a legacy is bequeathed is termed legatee. For an account of the legacy duties, see art. "Taxation," *Encyc. Britannica*, (new edition).

LE'GATE. (Lat. legatus.) A high functionary, in general a cardinal or bishop, whom the pope sends as ambassador to the courts of foreign powers. Legates are,—1. A Latere, who possess the highest degree of authority; 2. De Latere: the former are such as the pope commissions to take his place in councils. 3. Legates by office are such as enjoy the titular distinction of legate by virtue of their dignity and rank in the church, but have no special mission.

LEGATION. *See* AMBASSADOR. DIPLOMACY.

LEGA'TO. (Ital. *tied.*) In Music, a term used to denote the tying one note to another, which is done by placing these marks ⌣ ⌢ above or below the notes intended to be so joined. This is also known by the name of *sycope*.

LEGATU'RA. (Ital.) In Music. *See* DRIVING NOTES.

LEGA'TUS. (Lat.) In Roman History, an officer who acted as deputy under a commander-in-chief, and whose duty it was to aid the proconsuls and propraetors in the administration of the Roman provinces. Of the number of the legati nothing certain is known; though the probability is that there was one to every legion. In the absence of the consuls and other magistrates entitled to the *fasces*, this honour was conferred on the *legati*.

LE'GEND. (Lat. legenda, *things to be read.*) A book originally used at divine service in the Romish churches, in which are recorded the lives of saints and martyrs, portions of which were selected and read for the edification of the people. These legends, which contained many ridiculous stories of the lives of the saints, were studiously perused in the refectories of cloisters, and were earnestly recommended to the perusal of the laity, as so many evidences of the truth of the Roman Catholic faith. Among these the Golden Legend (the work of Jacobus de Voragine, archbishop of Genoa in the 13th century), which is a collection of the lives of the saints, maintained its ground in the church for two hundred years; though, from the number of ridiculous stories with which it teems, it has now sunk into merited oblivion. But although many of the legends consist of tasteless and unmeaning fictions, the offspring of a childish credulity, which indeed they were intended to gratify, there are many of them of a highly poetical and striking character; and hence it is not surprising that this species of literature has often been regarded, even by persons of taste, as a verdant oasis amid the desert of imaginative writings in the middle ages. There are some sensible remarks as to the value of the early Christian legends in Beugnot, *Hist. de la Destruction du Paganisme en Occident*, i. 280. In a general sense the term legend is used to denote any fictitious or doubtful narrative; such as the exploits of heroes of the middle ages, or the history of a people or district in which truth is so mixed with fable as to be inseparable from it.

LEGEND. In Numismatics, that which is written *round* the field of a medal; opposed to *inscription*, which is written across it. *See* NUMISMATICS.

LEGERDEMAIN. (Fr. *light of hand.*) A term given to some deceptive or sleight-of-hand performances, which depend either entirely on dexterity and address, or derive but a small degree of aid from philosophical principles. *See* MAGIC.

LEGGIA'DRO. (Ital.) In Music, a direction to the performer that the music to which the word is appended is to be performed gaily or briskly.

LE'GION. A division of the Roman army, comprising ten cohorts, thirty maniples, or sixty centuries; so that if there had always been one hundred men in each century, as its name imports, the legion would have consisted of six thousand men. But the number was in fact variable.

There were usually three hundred cavalry joined to each legion, which were divided into ten troops (turmae), and each of these troops into three bodies of ten men (decuriae). The defensive arms of the legionaries were an oblong shield, a helmet, hauberk, and greaves; their offensive weapons were a sword and two long javelins. The legion was drawn up in three lines; the soldiers in each of which were distinguished by the names Hastati, Principes, and Triarii. The Hastati, who formed the first line, were young men in the flower of life, and originally used long spears, which were, however, afterwards discarded. The Principes occupied the second line, and were men in the prime of life. The Triarii were veteran soldiers, and formed the third line. In each legion there were six military tribunes, who commanded under the consul, each in his turn, usually for about a month. This was the early organization of the legion, as it is known to us chiefly from the description of Livy, at the time of the great Latin war in the fifth century of the Republic. It was materially changed in later times; and the three original lines were discarded, probably about the time of the Punic war. But it always retained its distinctive character of a separate army, as it were, provided with its complement of cavalry and light infantry; and it has been remarked, as a striking proof of the military genius of the Romans, that after so many ages of additional experience, recent captains, and particularly Napoleon, have found it advantageous to divide their armies into separate corps, each in a similar manner complete, with its own cavalry and artillery; and these, in the French imperial armies, usually averaged from 4000 to 6000 men, or about the number of a Roman legion. The organization of the legion is explained in most works on Roman antiquities, but has been nowhere so thoroughly treated as by M. Le Beau, in a long series of memoirs which appeared from time to time in the *Mem. de l'Ac. des Inscriptions et Belles Lettres*. See particularly vols. xxxv. xxxvii. xxxix. The reader may also now consult *Dr. Arnold's History of Rome*, vol. ii.

LE'GION OF HONOUR. An order instituted by Napoleon when first consul of France for merit, both military and civil. The order consisted, under the Empire, of grand crosses, grand officers, commanders, officers, and legionaries. They were divided into sixteen cohorts, each of 407 members; but the total amount was afterwards much increased. Pensions, from 250 to 5000 francs per annum, were attached to these distinctions. After the restoration of Louis XVIII. the order underwent some modifications in its constitution, and its members were limited on a smaller scale. *See* HONOUR.

LEGISLATION. *See* LAW.

LE'GISLATOR. (Lat.) One who frames or establishes the laws and polity of a state or kingdom. The term is chiefly applied to some distinguished persons of antiquity, such as Moses among the Jews; Theseus, Draco, Solon, among the Athenians; Lycurgus among the Spartans; and Numa among the Romans.

LEGISLATURE. The name given to the body or bodies in a state in whom is vested the power of making laws. Thus the king, lords, and commons of Great Britain, whose united consent is indispensable to the framing of a law, are styled *the legislature*.

LEGI'TIMACY, in Politics, signifies, in its strictest sense, the accordance of an action or of an institution with the municipal law of the land. The principle of obedience to civil authority, in whatever hands the law has placed it, is consecrated by religion as well as by sound philosophy. Resistance to, or evasion of, the legal commands of a superior, is thus an offence against the law of God as well as of man, in things in themselves indifferent as well as in things commanded by the principles of morality. How far they must be obeyed when against the conscience of the subject, is one of those questions of casuistry which never can receive a solution applicable to all cases and circumstances. In this sense it is clear that the attribute of legitimacy belongs to no particular form of government, but is equally inherent in all when lawfully established. But, looking at the subject from a higher point of view, the question arises, when and how shall a government be taken to be lawfully established? This can only be directly answered by two classes of political philosophers. The first attribute the quality of legitimacy only to hereditary monarchical government, which they conceive to be peculiarly of divine appointment, deriving it from the patriarchal form of society. This theory has the advantage of simplicity; but its advocates have never been able to show any real foundation for it in the language of Scripture, and it is of course impossible to raise it on any other basis. (*See* DIVINE RIGHT, NON-RESISTANCE.) The second class bases society on the abstract rights of man, attributes all power to the people, and considers no government legitimate except such as is founded on their consent. This theory also is plain and clear in the abstract; but has the defect of becoming impossible in application. For, 1. The principle of the *social contract*, or implied consent of the people, is a mere philosophical fiction. 2. The actual consent of the people (*i. e.* the majority of it) to any existing form of government has never been satisfactorily ascertained. This is notoriously the case in every European country; and even the representative government of the United States of America is chosen by a constituency from which *slaves*, women, and persons under twenty-one years of age (that is, in all, five sixths of the population) are excluded. Now the exclusion of any one of these classes can only be justified on grounds of expediency; and similar grounds might equally justify the adoption of other tests (*e. g.* that of property, as in England and other European countries) which would still further reduce the number of the constituency. 3. Supposing a government established by the actual voices of a majority of the whole people, the question would still arise, whether every subsequent act of that

government was legitimatized by that original validity. This question was much debated in France at the period of the trial of Louis XVI.; when the Convention, elected itself by a majority of the people, was assuming the extraordinary power of judging that monarch. The Girondins, on that occasion, contended that an appeal to the people (*i. e.* to the suffrages of a majority of the constituents) was necessary in order to ratify the act; and in a greater or less degree it must always arise, whenever an alteration in circumstances since the period of the election of the representative body has called for the adoption of extraordinary measures. Between these two classes of theoretical politicians, the greater number are content to hold that the only fundamental principle of government is expediency, and its only right that given by municipal law or peaceable possession. In their view, all government is equally legitimate so soon as it is fairly established; while they fully admit that a question, and often a very difficult one, arises on every violent change of institutions, as to how soon the new government *de facto* has acquired the character of legitimacy. In the language of modern politics this word has acquired a peculiar sense; chiefly from its employment about the period of the Congress of Vienna, when the old hereditary dynasties were termed legitimate in contradistinction to those which the French revolution and subsequent wars had founded. Hence the principle of legitimacy has been, very incorrectly, opposed to that of representative or popular government; a mere abuse of terms, but an important one, from the powerful effect which words are able to produce in political discussion.

LEGI'TIMACY. (Lat. legitimus, *lawful.*) In Jurisprudence, the state of a child born in lawful wedlock.

LEGITIMA'TION. The act by which natural children are rendered legitimate. *See* GRETNA GREEN MARRIAGES, BASTARD.

LEGU'MEN. (Lat.) In Botany, a one-celled, one or many-seeded, two-valved, superior fruit, dehiscing by a suture along both its face and its back, and bearing its seeds on the ventral suture only. It differs from the follicle only in dehiscing by two valves. Sometimes it is indehiscent, as in *Cassia fistula*, &c.; but the line of dehiscence is in such species indicated by the presence of sutures. It is very near a drupe, into which it passes in many genera, such as *Dipteryx*, &c.

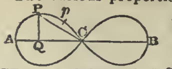
LEGU'MINO'SÆ. A very extensive natural order of Polypetalous Exogenous plants found in all parts of the world; forming large trees and huge twiners in the Tropics, and being herbaceous plants or small bushes, rarely trees, in colder countries. The order contains a great variety of useful and beautiful species, some of which, like clover, lucern, saintfoin, and vetches, are cultivated for cattle; others, as peas, beans, lentils, and various other kinds of pulse, form part of the food of man. Indigo, logwood, and many others are well-known dyeing plants; several acacias produce gum arabic; certain *Astragali* yield tragacanth; the tamarind and others bear pods whose interior is filled with an agreeable fæcula or pulp; *Cassia acutifolia* and others yield senna; *Glycyrrhiza* the liquorice root; *Ceratonia* the wild locust fruits of Scripture; finally, many are valuable tonics, and some are dangerous narcotics, among which the common laburnum is to be named. The larger part of this order consists of plants called Papilionaceous, because of a fancied resemblance between their flowers and a butterfly. Such plants have one large expanded petal, and four others much smaller, which form alæ and carina in front of the vexillum; but in others the more usual form of corolla is observed, and there are even some which, like *Ceratonia*, are apetalous. The division of the order called *Mimosa* is remarkable for having very small flowers with long stamens, and growing in balls or spikes.

LE'MMA. (Gr. λημμα, from λαμβανω, *I take or assume.*) In Geometry, a preliminary proposition, laid down for the purpose of facilitating or rendering more perspicuous the demonstration of a theorem, or the construction of a problem.

LE'MMING. A name given to a species of claviculate Rodents (*Georychus lemmus*, Ill.), very abundant in the north of Europe on the shores of the Arctic ocean. It is as large as a rat, with black and yellow fur, and is remarkable for its occasional migrations in innumerable bodies. At these periods the lemmings are said to march in a straight line, regardless of rivers or mountains; and, unimpeded by any obstacle, they devastate the country through which they pass. *See* GEORYCHUS.

LEMNI'SCATA. (Gr. λημνισκος, *a ribband.*) In Geometry, the name given to a curve of the fourth degree, having the form of the figure 8, and of which the equation is $x^2 + y^2 = a\sqrt{x^2 - y^2}$. There are many other curves of the same order having a similar form, but their equations differ from the above. The lemniscata, though a re-entering curve, is susceptible of indefinite quadrature; and its whole area is equal to the square of its semi-axis. It is a remarkable property of this curve that it is capable of being divided algebraically into equal though dissimilar portions.

The various properties of this curve are most easily derived from its polar equation.



Let C A $= a$, C Q $= x$, and P Q$=y$; the equation of the curve is $x^2+y^2=a\sqrt{x^2-y^2}$. Now let CP$=r$, and the angle P C Q$=u$; we shall have $x=r\cos. u$, and $y=r\sin. u$. Substituting these values of x and y in the equation of the curve, it becomes, after reduction, $r^2=a^2\cos. 2u$. But, by the general theory of curves, the differential of the area referred to polar co-ordinates is $\frac{1}{2}r^2\,du$; therefore in the present case d area $=\frac{1}{2}a^2\cos. 2u\,du$, and, integrating, C p P Q $=\frac{1}{2}a^2\sin. u\cos. u$. At the point C we have $r=0$; therefore $\cos. 2u=0$, and consequently $u=45°$. At this point, therefore, $\sin. u=\sqrt{\frac{1}{2}}$, and $\cos. u=\sqrt{\frac{1}{2}}$; and at the point A we have $u=0$, therefore the area comprised between C A and the curve A P p C $=\frac{1}{4}a^2$. Hence the whole area bounded by both branches (the two branches being similar) is equal to a^2, or the square of A C, which is $\frac{1}{2}$ A B.

Let P be any point in the curve, and p another point related to P by the equation cos. A C P × cos. A C $p=\sqrt{\frac{1}{2}}$; then the curvilinear arc A P is equal to Cp, which is the property above alluded to. A similar property, however, belongs also to some other curves. (See Legendre, *Exercises de Calcul Intégral*, tome i.)

LE'MONS, ESSENTIAL SALT OF. The binoxalate of potash is often sold under this name; it is chiefly used for removing iron-moulds and ink-stains from linen.

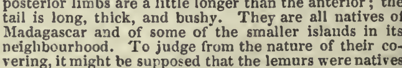
LE'MUR. (Lat. lemur, *a ghost.*) This term was applied in the Linnæan system to several of the lower Quadrumanous animals of different structure and habits; it is now restricted to those which have the inferior incisors long, compressed, straight, and sloping forwards, and the lower canines approximated, and of similar form and direction, differing only in a slight increase of size, whence they have usually been enumerated as incisors: the upper incisors are straight, and the intermediate ones are separated from each other. The long pointed canines of the upper jaw are principally opposed to the trenchant anterior false molars below. Each of the four extremities is provided with an opposable thumb; but the index digit of the hinder hand has its nail developed into a long, curved, sharp-pointed claw. The use of this claw is to clean or dislodge vermin from the long and thick woolly hair. The lemurs deviate from the typical Quadrumanes, and approximate to the ordinary quadruped in their elongated pointed head and sharp projecting muzzle; the posterior limbs are a little longer than the anterior; the tail is long, thick, and bushy. They are all natives of Madagascar and of some of the smaller islands in its neighbourhood. To judge from the nature of their covering, it might be supposed that the lemurs were natives of a cold climate; but their fur has relation to the season of their activity. They sleep by day, and move about in the night season, during which time the air is often sufficiently cold in the tropical latitudes. Their nutriment is a mixed diet of fruits, insects, and small birds; the latter they surprise while at roost.

LE'MURES. Male and female genii, or infernal gods, believed by the ancient Romans to haunt solitary rooms and silent places: they were propitiated by casting beans to them. Their feast was celebrated under the name of Lemuria or Lemuralia.

LE'MURIDÆ. (Lat. lemur, *a ghost.*) The family of Quadrumanous Mammals of which the genus *Lemur* is the type; it includes the genera *Tarsius*, *Otolicnus*, *Stenops*, *Lichanotus*, and *Lemur* proper: see those terms.

LENS. (Lat.) In Optics, a thin piece of glass or any other transparent substance, bounded on both sides by polished spherical surfaces, or on the one side by a spherical and on the other by a plane surface; and having this property, that parallel rays of light in passing through it have their direction changed, so as to converge to a given point called the *principal focus* of the lens, or to diverge as if they proceeded from that point.

Lenses receive different denominations according to their different forms. Thus,



A *spherical lens*, shown at A, is a sphere or globule of glass.

A *double convex lens*, shown at B, is a solid formed by two convex spherical surfaces; and is *equally convex*, or *unequally convex*, according as the radii of its two surfaces are equal or unequal.

A *plano-convex lens*, C, is that of which one of the surfaces is *plane*, and the other *convex*.

A *double concave lens*, D, is bounded by two *concave* spherical surfaces, which may have either the same or a different curvature.

A *plano-concave lens*, E, has one surface *plane*, and the other *concave*.

A *meniscus*, F (so called from its resemblance to a

little moon), is a lens of which one of the surfaces is *convex* and the other *concave*, and which meet if continued. The radius of the convex surface is consequently smaller than the radius of the concave.

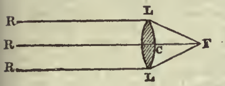
A *concavo-convex lens*, G, is that of which one of the surfaces is *concave* and the other *convex ;* but in this case the surfaces will not meet though continued, the radius of the concave surface being smaller than that of tne convex one.

The straight line M N which passes through the centres of all the curved surfaces, or is perpendicular to both surfaces of the same lens, is called the *axis* of the lens ; and it is in this line that the focus of the lens is situated.

It was observed, at an early period, that a transparent body of a spherical form has the property of collecting at the focus the parallel rays of light which fall on its surface. But it was remarked, at the same time, that the illumination at these foci was extremely feeble, in consequence of the thickness of the glass which the light had to pass through. This inconvenience is removed by taking only two small segments instead of the entire sphere ; by which means, as the refraction takes place only at the surfaces, and not in the interior of the glass, the very same refraction of the rays is produced as when the whole sphere is used ; and the thickness of the glass being greatly diminished, the rays pass through it in much greater number, and the intensity of the light in the focus is much more considerable.

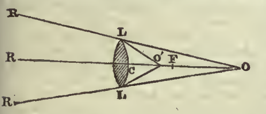
The rules for finding the focal distances of the different sorts of lenses are the following. They depend in some measure on the refracting power of the glass. We shall here suppose the index of refraction to be 1·500.

1. Rays of light, R L, R L, falling on a convex lens in directions parallel to the axis, are refracted into the point F, which is called the principal focus. In a *double* and *equally* convex lens the distance of F from C, the centre of the lens, is equal to the radius of the spherical surfaces.



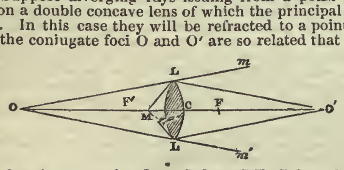
If the lens is *plano-convex*, the focal distance is equal to twice the radius of the spherical surface. If the lens is unequally convex, its focal distance is found by this rule : — Multiply the two radii of its surfaces, and divide twice that product by the sum of the radii ; the quotient will be the focal distance required.

2. When the rays falling on a convex lens whose principal focus is F converge towards a point O, their convergency will be hastened, and they will be refracted into a point O′, which is nearer the lens than the principal focus F.



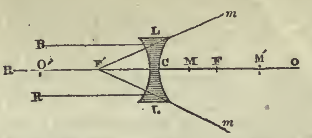
The two points O and O′ are called *conjugate foci ;* and they are related to each other in such a manner that C O′ is a fourth proportional to C O + C F, C O and C F. Hence, when the point O is given, the conjugate focus O′ will be found by this rule : — Multiply the principal focal distance C F by C O, and divide the product by the sum of those numbers. It is obvious that as the distance of O becomes greater, O′ approaches to F, and when O is at an infinite distance O′ coincides with F.

3. Suppose diverging rays issuing from a point O to fall on a double concave lens of which the principal focus is F. In this case they will be refracted to a point O′ ; and the conjugate foci O and O′ are so related that C O′



is a fourth proportional to C O — C F, C O and C F. Hence O′ is found by the following rule : — Multiply the principal focal distance C F by C O, and divide the product by the difference between C O and C F. As the point of divergence O recedes from the lens, the point O′ approaches nearer to F ; and when O is at an infinite distance, O′ coincides with F. As O approaches the lens, O′ recedes from it ; when O is at F′ (the focal distance) the refracted rays become parallel to the axis ; and when O is between F′ and C, as at M, the refracted rays diverge in the directions L *m*, L *m′*.

4. The focal distance of a concave lens is the same as that of a convex one whose surfaces have the same curvature, and the rules for finding the conjugate foci are precisely the same ; but the rays, instead of being collected, are scattered by passing through a concave lens, and the principal focus is on the same side as the point from which the rays proceed. Parallel rays R L, R C, R L, falling on the concave lens L L in the direction of the axis, become divergent, as if they proceded from F′ (the principal focus). When the rays which fall on a concave lens converge towards the point F, they are refracted in the direction parallel to the axis.



When the incident rays converge to a point O beyond F, the refracted rays diverge, as if they proceeded from a conjugate point O′, also farther from the lens than F′ ; and when the incident rays converge towards a point M, between C and F, the refracted rays will be convergent, and meet in a conjugate point M′ on the same side of the lens with M. These conjugate foci are determined by the rules which have been given for convex lenses. Lastly, when the incident rays diverge from a point O′, farther from the lens than the principal focus, the refracted rays will be more divergent, and proceed as if they emanated from a point between the principal focus and the lens. The rule is, in this case, also the same as for convex lenses.

5. The effect of a meniscus is the same as that of a convex lens of the same focal distance ; and that of a concavo-convex lens the same as that of a concave lens of the same focal distance. The principal focal distance is found by this rule : — Divide twice the product of the two radii by the difference of the radii.

6. The above rules for finding the principal and conjugate foci of the several kinds of lenses may be all expressed by two simple algebraic formulæ. Let R denote the radius of the anterior surface (or that at which the light enters), S that of the posterior surface, and let R and S be considered as positive when the surfaces, are convex, and negative when concave. Also, let F denote the distance of the principal focus, and *n* the index of refraction ; then, neglecting the thickness of the lens as inconsiderable, the formula which gives the principal focus is

$$\frac{1}{F} = (n-1)\left(\frac{1}{R} + \frac{1}{S}\right) \ldots . (1.)$$

For the conjugate foci of convergent and divergent rays, let U be the distance C O of the focus of the entering rays, and V the distance C O′ of the focus of the emerging rays ; and let U be considered as negative when the entering rays are *divergent*, and V negative when the emerging rays are *convergent ;* then,

$$\frac{1}{U} + \frac{1}{V} = \frac{1}{F}, \text{ or } V = \frac{U\,F}{U - F} \ldots . (2.)$$

the point F being determined by the formula (1.)

For the application of these formulæ to the different cases, and the correction to be made for the thickness of the lens, see *Coddington's Treatise on the Reflexion and Refraction of Light.*

In deducing the above rules it has been assumed that the focus into which the rays are refracted is a mathematical point ; but this is not strictly true, unless the rays only fall on the lens very near its centre, by reason of the *spherical aberration.* (*See* ABERRATION.) For the correction of the *chromatic aberration*, arising from the unequal refrangibility of the luminous rays, *see* ACHROMATISM. *See* also LIGHT, OPTICS, and REFRACTION.

LENS-SHAPED, or LENTICULAR, or LENTIFORM. A term used in describing the general figure of bodies, to denote their resembling a double convex lens ; as the seeds of Amaranthus.

LENT. A solemn time of fasting in the Christian church ; so called from the Anglo-Saxon signifying spring. The term of Lent comprises the forty days before Easter, by which it is determined. The period of time is intended to commemorate the fasting of our Saviour in the wilderness. *See* EASTER.

LE'NTE, or LENTO. (Ital.) In Music, a direction to the performer that the music to which the word is prefixed is to be performed slowly.

LE'NTIBULA'RIA'CEÆ. A very small natural order of Herbaceous Exogens, natives of the marshes and waters of all parts of the world. They are nearly allied to *Scrophulariaceæ*, but are distinguished by their free central placenta and minute exalbuminous embryo ; from *Primulaceæ* by their irregular flowers, their stamens, and their ovary. The beautiful *Pinguicula*, a wild plant in marshes, is one of the genera, and *Utricularia* another. They are of no known use.

LE'NTICELLES, or LENTICULAR GLANDS. A term invented by De Candolle to denote certain minute speck-like tubercles on stems. Notwithstanding the importance assigned them by this great botanist, his lenticelles appear to be nothing more than the points of roots attempting to spring from the surface of bark.

LENTI'GO. A freckle of the skin ; so named from its resemblance to a lentil seed.

LE'NZINITE. A hydrated silicate of alumina, found

at Eifield in Prussia; it is white, translucent, and falls into small hard grains when put into water.

LE'O. (Lat. *a lion.*) One of the zodiacal constellations, situated chiefly on the northern side of the ecliptic. The star *Regulus*, called also *Cor Leonis*, belongs to this constellation.

LE'O MI'NOR. The Little Lion: a constellation of the northern hemisphere, between Leo and Ursa Major. This constellation has been formed by the moderns, and is not given in Ptolemy's catalogue.

LE'ONINE VERSES. Latin verses according to the rules of ancient prosody, but rhymed. The name is said to be derived from one of the popes Leo, or, more probably, from a monk called Leoninus. The end rhymes to the middle, *i. e.* to the two last syllables before the cæsura, in hexameters; in pentameters, the two divisions are rhymed. The following distich may serve as an example:—

Dæmon languebat, monachus tunc esse volebat;
Ast ubi convaluit, mansit ut ante fuit.

LE'PADITES, *Lepadita.* (Gr. λεπας, *a shell-fish.*) Goose barnacles; an order of Cirripeds, comprehending those which have a long flexible contractile stem, fixed by its base to some solid body, and supporting at its extremity the principal parts of the animal, inclosed by a multivalve shell, or coriaceous case.

LE'PADOGA'STER. (Gr. λεπας, and γαστηρ, *stomach.*) A genus of Discobolous Malacopterygian fishes, having the following characters: pectoral fins expanded, with stouter rays at their lower edges, which curve slightly forwards, and unite with each other beneath the throat by means of a transverse membrane directed forwards, constituting the boundary of an adhesive disk, close to which there is a second, formed by the union of the ventrals; body smooth, and without scales; head broad and depressed; snout salient and protractile; branchiæ slightly cleft, and furnished with four or five rays; dorsal fin single, and opposite to the anal, which is near the tail. Of this genus we possess two native species; one of which, called the Cornish sucker (*Lepadogaster cornubiensis*), was discovered by Dr. Borlase on the coast of Cornwall; the other (*Lepadogaster bimaculatus*) has been taken on different parts of the South Weymouth coast. Both species adhere by means of their ventral suckers to rocks, stones, &c., whence the generic name: they feed principally on Crustacea.

LE'PALS. A term invented to denote stamens that are sterile. It is very rarely used.

LEPI'CENA. A term invented by Richard to denote the two empty bracts situated at the base of the locusta of a grass, and usually called glumes.

LE'PIDOIDS. A family of extinct fossil fishes belonging to the oolitic formation, remarkable for their large rhomboidal bony scales. Figures of these scales are given in *Dr. Buckland's Bridgewater Treatise.*

LE'PIDOLITE. (Gr. λεπις, *a scale*, and λιθος, *stone.*) A mineral of granular and foliated texture, moderately hard, of a pinkish colour. It contains lithia.

LEPIDO'PTERA. (Gr. λεπις, and πτερον, *a wing.*) The third order of insects in the system of Linnæus, and the tenth in that of Latreille, who has given the following concise and comprehensive description of the characters common to the insects of this most interesting, useful, and beautiful group.

The wings are four, covered on both sides with minute generally coloured scales, resembling farinaceous dust, which are removed by merely coming in contact with the finger. The oral apparatus consists principally of a proboscis, to which the name of *antlia* has been given, which is rolled spirally between two palpi, covered with scales or hairs. This forms the most important part of the mouth, and is the instrument with which these insects extract the nectar from flowers, their only aliment. It is composed of two tubular threads, representing the maxillæ, each bearing, near its external base, a very small superior palp, in the form of a tubercle. The apparent (inferior) palpi, which form a sort of sheath to the proboscis, replace the labial palpi of the mandibulated insects: they are cylindrical or conical, usually turned up, composed of three joints, and inserted in a fixed labium, which completes that portion of the buccal cavity inferior to the proboscis. Two little and scarcely distinct, corneous, and more or less ciliated pieces, situated, one on each side, on the anterior and superior margin of the front of the head, near the eyes, seem to be vestiges of mandibles. Finally, we observe, and under an equally small proportion, the labrum or upper lip.

The antennæ vary, and are always multi-articulated. Two ocelli are observable in several species, but concealed between the scales. The three segments of which the thorax is usually composed are united in one single body; the first is very short, and the two others are blended together. The scutellum is triangular, but the apex is directed towards the head. The wings are simply veined, and vary in size, figure, and position; in several the inferior ones are plaited longitudinally near the inner margin. At the base of each of the superior wings is a kind of epaulette, prolonged posteriorly, which corresponds to the piece called *tegula* in the Hymenoptera. The abdomen, composed of from six to seven annuli, is attached to the thorax by a very small portion of its diameter, and presents neither sting nor ovipositor. In several females, however, as in *Cossus*, the last rings become narrowed and extended, to form an oviduct resembling a pointed and retractile tail. The tarsi always have five joints. There are never more than two kinds of individuals, males and females.

The females usually deposit their ova, frequently very numerous, on the vegetable surfaces which are to nourish their larvæ, and soon after perish.

The larvæ of Lepidopterous insects are well known by the name of caterpillars. They have six squamous or hooked feet, which correspond to the legs of the perfect insect, and from four to ten additional membranous ones, or *propedes;* the two last of which are situated at the posterior extremity of the body. Those caterpillars which have but ten or twelve in all have been called, from their mode of progression, *geometræ.* Several of these geometers, when at rest, remain fixed to the branches of plants by the hind feet alone, whence in the form, colour, and directions of their body, they resemble a twig. They can support themselves in this position for a long time without exhibiting the slightest symptom of life. So fatiguing an attitude must require prodigious muscular force; and, in fact, Lyonnet counted 4041 *muscles* in the caterpillar of the *Cossus ligniperda.*

The body of these larvæ is generally elongated, almost cylindrical, soft, variously coloured; sometimes naked, and sometimes covered with hairs, tubercles, and spines. It is composed of twelve segments or annuli, exclusive of the head, with nine stigmata on each side. Their head is invested with a corneous or squamous dermis, and presents on each side six shining granules, which appear to be ocelli; and it is furnished with two very short and conical antennæ, and a mouth composed of strong mandibles, two maxillæ, a labrum, and four small palpi. The silk which they use is elaborated in two long and tortuous internal vessels, of which the attenuated superior extremities terminate in the lip. A tubular and conical mamilla forms the spinnaret through which the threads are spun.

Most caterpillars feed on the leaves of plants; some gnaw their flowers, roots, buds, and seeds; others attack the ligneous or hardest part of trees, softening it by means of a fluid which they disgorge. Certain species attack our woollens and furs, thereby doing us much injury; even our leather, bacon, wax, and lard, are not spared by them. Several confine themselves exclusively to a single article of diet; others are less delicate, and devour all sorts of organized matters.

Some of them form societies, and frequently live under a silken tent, spun by them in common, which even shelters them in winter. Several construct sheaths for themselves, either fixed or portable; others make their abode in the parenchyma of leaves, where they form galleries. The greater number are diurnal: the others never issue forth but at night. The severity of winter, so fatal to almost all insects, does not affect certain *Phalænæ*, which only appear in that season.

Caterpillars usually change their skin four times previously to passing into the state of a nymph or chrysalis. Most of them spin a cocoon in which they enclose themselves. A frequently reddish liquor, which Lepidopterous insects eject at the moment of their metamorphosis, softens or weakens the extremity of the cocoon, and facilitates their exit: one of these extremities, also, is generally thinner than the other, or presents a favourable issue by the peculiar disposition of the fibres. Other caterpillars are contented with connecting leaves, particles of earth, or of the substances on which they have lived, and thus forming a rude cocoon. The nymphs of the diurnal Lepidoptera are ornamented with golden spots, whence the term *chrysalis* applied to them: they are naked, and fixed by the posterior extremity of the body. The nymphs of all the Lepidoptera are swathed, or resemble mummies. Those of several insects of this order, particularly of the *Diurnæ*, undergo their metamorphosis in a few days; they even frequently produce two generations in the course of the year. The caterpillars or chrysalides of others, however, remain during the winter in one of these states, and undergo their final transformation in the ensuing spring. The Lepidoptera issue from their nymphal envelop through a slit, which is effected in the back of the thorax.

LE'PIDOPUS. (Gr. λεπις, and πους, *a foot.*) A genus of Tænioid fishes, characterized by the reduction of the ventral fins to the condition of small scaly plates. The thin and elongated body is without scales: it is furnished with a dorsal fin, which extends its whole length, and a narrow anal fin; it terminates in a well-formed caudal. The branchiostegous rays are eight in number; the head is pointed, with a single row of laniary teeth in each jaw, the largest above, and others, very small, on the

palatine and pharyngeal bones. Of this genus one native species is known, called the Scabbard-fish (*Lepidopus argyreus*). It is very rare: only four examples are recorded by Mr. Yarrell, which were taken on the southern shores.

LEPIDO'TUS. In Palæontology, the name of a fossil fish, distinguished by its large, thick, rhomboidal, enamelled scales, and its hemispherical or obtusely conical teeth: its remains are widely diffused through the wealden formation.

Lepidotus. In Botany, Latin term for leprous.

LE'PIS. (Gr. λεπις, *a scale.*) A scale or scurf, consisting of a thin transparent membrane attached by its middle, and, owing to the imperfect union towards its circumference of the cellular tissue of which it is composed, having a lacerated irregular margin. It gives origin to the adjective Lepidote.

LEPI'SMA. (Gr. λεπισμα, *decortication.*) A Linnæan genus of Apterous insects, forming the first family of Thysanourous insects in the system of Latreille. The body of these apterans is elongated, and covered with small scales, frequently silvery and brilliant; from which circumstance the most common species has been compared to a little fish. The antennæ are setaceous, and usually very long. The feet are short, and frequently have very large and strongly compressed coxæ, resembling scales. These insects run with great velocity: some of them, by means of their caudal appendage, are enabled to leap. Several species conceal themselves in the cracks of the framework of windows, in wardrobes, under damp boards, &c.: others hide beneath stones.

Lepisma. In Botany, a term sometimes applied to the cup-shaped disk of *Pæonia* and *Aconitum;* but seldom employed.

LEPI'SMIDÆ. The family of Thysanourous insects of which the genus *Lepisma* is the type. It includes the genera *Lepisma* proper, and *Machiles*. See those words.

LEPO'RIDÆ. The hare tribe, or the family of Rodents of which the genus *Lepus* is the type.

LE'PRA. (Gr. λεπρος, *rough.*) The leprosy; a disease of the skin, characterized by scaly patches, nearly of a circular form. The cuticle becomes reddish and scaly; at first upon some one spot, often the knee, and thence gradually spreads over the body, which becomes stiff and uncomfortable, and most unseemly in appearance. Friction, warm baths, sulphur baths, and afterwards slightly stimulating ointments, such as pitch ointment, or weak citrine ointment, with light and moderate diet, and careful abstinence from wine and stimulants, are the principal means of cure. This disease appears to have been of much more frequent occurrence in ancient than in modern times; but it is generally believed that the *lepers* mentioned in the sacred and profane authors were afflicted with a disease resembling more that known by the name of elephantiasis than leprosy.

LEPTOCE'PHALANS. *Leptocephalidæ.* (Gr. λεπτος, *slender;* κεφαλη, *a head.*) The name of a family of fishes characterized by the smallness of the head, of which the genus *Leptocephalus* is the type.

LEPTOCE'PHALUS. A genus of Apodal Malacopterygian fishes, in the system of Cuvier, characterized by a very small and short head, and a remarkably compressed and delicate body: the pectoral fins and branchial apertures are very small; the dorsal and anal fins are narrow, and united at the point of the tail. One species of this rare and singular genus was discovered near Holyhead, and was described by Gronovius under the generic name of *Leptocephalus*, in reference to the diminutive size of the head. The *Leptocephali* are more common in the seas of hot climates.

LEPTU'RA. (Gr. λεπτος, *slender*, οὐρα, *a tail.*) A Linnæan genus of Longicorn beetles, now the type of an extensive family (*Lepturidæ*), in which the eyes are rounded and entire, or, if slightly emarginate, with the antennæ inserted before the emargination. The head is always inclined posteriorly behind the eyes, or is abruptly contracted at its junction with the thorax, in the manner of a neck; the thorax is conical or trapezoidal, narrowed anteriorly; the elytra become gradually narrower. The term *Leptura* is now restricted to those Lepturidans in which the head is abruptly narrowed immediately behind the eyes; the antennæ inserted near the anterior extremity of the internal emargination of the eyes, the two eminences from which they rise being almost confounded in one plane. The thorax is almost always smooth, or without lateral tubercles.

LE'PUS. (Lat. *a hare.*) A genus of Rodents peculiarly distinguished by having their superior incisors double; *i. e.* each of them has a smaller one behind it. The molar teeth are also more numerous than in most other Rodentia, there being six on each side of the upper jaw, and five on each side of the lower jaw: the ears are very long, the tail short and turned up. The species of this genus are called hares and rabbits. The eyes are large and prominent, and, with the well-developed ears, serve to announce to these timid and defenceless animals remote objects and sounds of peril: the strength and proportions of the limbs, of which the hind pair is much longer than the fore, enable them to escape by rapid flight. The smaller species, as the rabbit, add to their means of safety by burrowing in the soil. Among the anatomical characters of the genus *Lepus* may be reckoned the rudimental condition of the clavicles, and the reticulate bony structure of the infra-orbital spaces.

Lepus. The Hare. In Astronomy, one of the forty-eight ancient constellations of Ptolemy, situated in the southern hemisphere.

LERNÆIFO'RMES. (Lat. lernæa, *a parasitic worm;* forma, *form.*) The name of a family of Siphonostomous Crustaceans, comprehending those with a long vermiform body.

LERNE'A. (Gr. λερναια, *a name of the hydra.*) A Linnæan genus of low-organized crustaceous animals, all of which are external parasites of fishes, and constitute the class *Epizoa* of modern systems.

LE ROI LE VEUT. (Fr. *the sovereign wills it, or assents.*) A form of words by which the royal assent is intimated by the clerk of parliament to the passing of public bills. To private bills the royal assent is expressed by *Soit fait comme il est desiré*. The dissent of the sovereign to the passing of any measure is signified by the words *Le roi s'avisera*. *See* Parliament.

LE'SSONS (Lat. lego, *I read*), are certain portions of the scriptures read in most Christian churches during divine service, the performance of which in the ancient church devolved, among other duties, on the catechumen. In the English church, the course of lessons begins with the year at the book of Genesis, and, with the omission of the two books of Chronicles, continues through the Old Testament, including portions of the Apocrypha.

In the *second* lessons, as they are called, the same course is followed with the New Testament. In the Presbyterian church the word *lesson*, in this sense, is unknown, though the practice of reading a portion of scripture is almost universally adopted; but the selection of the passage is left to the choice of the officiating clergyman.

LESTRIS. (Lat. *a robber.*) A subgenus of Gulls, separated from the *Larus* proper on account of their large membranous nostrils opening nearer the point and edge of the beak, and their tail being pointed. They pursue the small gulls with singular pertinacity and boldness to rob them of their food; and hence their name.

LE'THARGY. (Gr. ληθη, *forgetfulness.*) A heavy unnatural slumber, sometimes bordering upon apoplexy, from which persons are difficultly roused. It sometimes arises from a plethoric state of habit, in which case it requires depletion; but it often also is a symptom of over fatigue of mind, and then nervous remedies are indicated.

LE'THE. (Gr. ληθη.) In Greek Mythology, the River of Oblivion: one of the streams of the infernal regions. Its waters possessed the quality of causing those who drank them to forget the whole of their former existence. In the sixth book of *Virgil's Æneid*, the shades of the departed, after fulfilling their various destinies in the infernal regions during a thousand years, are brought to drink of the water of Lethe, as a preparation for their transmigration into new bodies.

> Has omnes, ubi mille rotam volvêre per annos,
> Lethæum ad fluvium deus evocat agmine magno;
> Scilicet immemores supera ut convexa revisant,
> Rursus et incipiant in corpora velle reverti.

The beautiful verses of Milton are well known: —

> Far off from these, a slow and silent stream,
> Lethe, the river of oblivion, rolls
> Her watery labyrinth: whereof whoso drinks
> Straightway his former sense and being forgets —
> Forgets both joy and grief, pleasure and pain.

Nor is the "slow and silent stream" less exquisitely described by Dante: —

> Tutte l'acque, che son di là più monde,
> Parrieno avere in se mistura alcuna
> Verso di quella, che nulla nasconde;
> Avvegnaché si muova bruna bruna
> Sotto l'ombra perpetua, che mai
> Raggiar non lascia sole ivi, nè luna.

Geographers have placed the river Lethe (that is, its supposed issue on the surface of the earth) in Bœotia, near Lebadea, in Crete, and on the coast of Africa. There was also a river of oblivion (limia oblivionis) in Spain, now the Lima.

LE'TTER. (Lat. litera.) A character used to express one of the simple sounds of the voice. Letters properly combined form the visible signs of those sounds by which we communicate our ideas. What letters were originally, who first invented them, and among what people they were primarily used, are still questions of profound obscurity. Philo, says the *Ency. Brit.*, attributes this great and noble invention to Abraham; St. Irenæus and others to Enoch; Bibliander to Adam; Eusebius, Clemens Alexandrinus, Cornelius Agrippa, and others, to Moses; Pomponius Mela, Herodian, Rufus Festus, Pliny, Lucan, and others, to the Phœnicians; St. Cyprian to Saturn; Plato and Tacitus to

the Egyptians; some to the Ethiopians, and others to the Chinese, who cannot possibly be entitled to this honour, since all their characters are the signs of simple ideas, and have nothing in common with letters. Various also are the conjectures concerning the different kinds of letters used in different languages. Thus, Moses is supposed by Crinitus to have invented the Hebrew letters; Abraham the Syriac and Chaldæic; the Phœnicians those of Attica; Nicostrata the Roman; Isis the Egyptian; and Vulfilas those of the Goths. All these statements, however, are purely conjectural; and it would be vain to examine the foundation on which they are based. Letters are distinguished by grammarians into vowels, and consonants (which latter are again subdivided into mutes and liquids), and diphthongs, according to the organ employed in their pronunciation. *See* ALPHABET, LANGUAGE.

LETTER, in Printing, is the usual term for an aggregate quantity of types in a printing office; as when a work is put in hand, and there happens to be a great quantity of type of the proper sort unemployed, it is usual to say "there is plenty of letter;" and, on the contrary, "there is a scarcity of letter."

LETTER OF CREDIT. A letter written by one merchant or correspondent to another, requesting him to credit the bearer with a certain sum of money. The bearer should be described with as many particulars as possible, lest the letter fall improperly into other hands.

LETTER OF LICENCE. An instrument by which creditors allow a party who has failed in his trade time for payment of debts and management of affairs.

LETTER OF ATTORNEY. A document by which a party gives another, named therein, power to do certain lawful acts in his stead, the party so authorized being called his attorney; such as to give seisin of lands; sue; or receive rents debts, and dividends.

LE'TTERS OF MARQUE. *See* MARQUE.

LE'TTERS PATENT, or LETTERS OVERT, in Law, are letters of the king, open, but sealed at the foot with the great seal of England, conferring some privilege whereby a party is enabled to do or enjoy that which otherwise he could not. Such are letters patent to make denizens, to protect inventions, &c.

LEU'CIN. (Gr. λευκος, *white.*) A white pulverulent substance, obtained by the action of dilute sulphuric acid on muscular fibre. It combines with nitric acid, forming the *nitro-leucic acid.*

LEU'CITE. (Gr. λευκος.) A crystallized mineral, of a grey or white colour, generally opake, and something resembling the garnet in form. It usually occurs in lava, especially in that of Vesuvius; hence it is also termed *Vesuvian* and *volcanic garnet.*

LEUCO'MA. A white opacity of the cornea of the eye, arising from inflammation.

LEUCOPE'TRIANS. In Ecclesiastical History, the name of a fanatical sect of Christians which sprang up in the Greek and Eastern churches towards the close of the 12th century. The tenets which they embraced were peculiarly strict; while they rejected all the outward ceremonies of religion, and spent their whole time in prayer and supplication to the Deity. They derived their name and origin from an enthusiast, Leucopetrus, of whom little is known beyond his name

LEU'COPHLEGMA'TIC. A pallid flabby state of body.

LEVA'NT (It. levante, *rising*), in Geography, is applied in a general sense to any country situated to the eastward of us, or in the eastern part of any continent or country; but, in a more contracted signification, it is given to that part of the Mediterranean sea bounded by Asia Minor on the north, Syria and Palestine on the east, Egypt and Barca on the south, and by the island of Candia and the rest of the Mediterranean on the west.

LEVA'RI FACIAS. In Law, a writ of execution directed to the sheriff, whereby he is commanded to levy a sum of money upon the lands and tenements, goods and chattels, of a man who has forfeited his recognizances. It is superseded in practice by the writ of elegit, except in cases of outlawry.

LEVA'TOR MUSCLES. Those which lift the part to which they are attached.

LE'VEE (Fr. lever, *to rise*), is the term used in court language for the ceremonial visits which distinguished personages receive in the morning; or, as the word implies, at their *rising*. It is chiefly applied in this country to the stated public occasions on which her Majesty receives visits from such of her subjects as are entitled by rank or fortune to the honour. The difference between a *lévee* and a *drawing-room* consists in this,—that while at the former gentlemen alone appear (with the exception of the chief ladies of the court), both ladies and gentlemen are admitted to the latter.

LEVEE EN MASSE. (Fr. literally *an universal rising.*) A military expression for the rising of a whole people to defend their country from invasion. In Germany it is styled landsturm, in contradistinction to the landwehr or militia (*quod vide*); and there, as in Spain and Tyrol, its efforts have often proved instrumental in rescuing the country from foreign invasion.

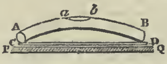
LE'VEL. An instrument which shows the direction of a straight line parallel to the plane of the horizon.

The plane of the sensible horizon is indicated in two ways: by the direction of the plummet or plumb-line, to which it is perpendicular; and by the surface of a fluid at rest. Accordingly, levels are formed either by means of the plumb-line, or by the agency of a fluid applied in some particular manner. They all depend upon the same principle, namely, the action of terrestrial gravity.

Levels in which the plumb-line forms the essential part are those most usually employed for the common purposes required by bricklayers, masons, carpenters, &c. They are constructed under many different forms; but the general principle is as follows:—A frame or board is prepared, having one edge perfectly straight, and a straight line is drawn on the frame at right angles to the straight edge. To some point of this straight line a thread carrying a plummet is attached; consequently, when the frame is placed in such a position that the thread of the plummet, hanging freely, coincides with the straight line, the straight edge of the frame, which is perpendicular to it, must be horizontal. *See* PLUMMET.

The *Artillery Foot Level*, and the *Gunner's Level*, besides the line and plummet, have a scale for showing the inclination of a straight line to the horizon. The former has two equal legs or branches placed at right angles; and from their point of junction a thread and plummet hangs, and plays over a quadrant divided into twice 45° from the middle. The plane or line on which the two ends rest is horizontal when the thread falls over the zero point of the scale; and when it falls over any other point, the degree marked on the scale indicates the inclination of the line to the horizon. The gunner's level is on the same principle, though differently constructed; the thread or plummet being replaced by a solid piece of brass, loaded at the lower end, and the legs, or rather the edges, of the brass plate making an angle of 45°. It is used in the same manner as the former.

Spirit Level.—By far the most convenient and also the most accurate level is the spirit level, represented in the annexed figure; "which is nothing more than a glass tube nearly filled with a liquid (spirit of wine being now generally used, on account of its *mobility* and not being liable to freeze), the bubble in which, when the tube is placed horizontally, would rest indifferently in any part if the tube could be made mathematically straight; but that being impossible to execute, and every tube having some slight curvature, if the convex side be placed upwards the bubble will occupy the higher part, as in the figure (where the curvature is purposely exaggerated). Suppose such a tube as A B firmly fastened on a straight bar C D, and marked at *a b*, two points distant by the length of the bubble; then, if the instrument be so placed that the bubble shall occupy this interval, it is clear that C D can have no other than one definite inclination to the horizon; because, were it ever so little moved one way or other, the bubble would shift its place, and run towards the elevated side. Suppose now that we would ascertain whether any given line P Q be horizontal; let the base of the level C D be set upon it, and note the points *a b*, between which the bubble is exactly contained; then turn the level end for end, so that C shall rest on Q, and D on P: if then the bubble continue to occupy the same place between *a* and *b*, it is evident that P Q can be no otherwise than horizontal; if not, the side towards which the bubble runs is highest, and must be lowered. Astronomical levels are furnished with a divided scale, by which the places of the ends of the bubble can be nicely marked." (*Herschel's Astronomy*, p. 92.)

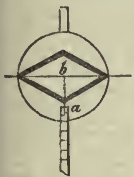


The accuracy of the indications of the level depends in a considerable degree on the regularity of the interior surfaces of the tube. They are commonly made of glass tubes in the same state as they are obtained at the glass-house; but when very great accuracy is required, as in astronomical observations, the interior surfaces are sometimes ground so as to give them a regular cylindrical, or rather spindle form, with a slight spherical curvature. The tube and bubble must be of considerable length. The larger the bubble the more freely it moves, and consequently the more sensible is the level to a small inclination. With proper care they can be executed, it is said, with such delicacy as to indicate a single second of angular deviation from exact horizontality.

LE'VELLERS. In English History, a party which arose in the army of the Long Parliament, about the time when it overawed that assembly, and transferred the king

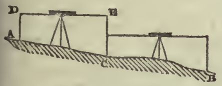
to Hampton Court, in 1647. The levellers professed, what their name implied, a determination to level all ranks, and establish an equality in titles and estates throughout the kingdom. Several of the officers belonging to this party were cashiered in 1649; and, on Cromwell's departure for Ireland in the end of that year, they raised mutinies in various quarters occupied by the army, and were put down by Fairfax with some bloodshed. John Lilburne, one of the chiefs of the faction, — of whom it was said that, "if none but he were left alive in the world, John would quarrel with Lilburne,"—published, in 1649, his *Manifestation from J. Lilburne and others, styled Levellers*. (See *Clarendon*, books x. and xii.; *Godwin's History of the Commonwealth.*)

LEVELLING STAVES. Instruments used with the spirit level, for supporting a mark, and showing at the same time its height above the ground. As constructed by Troughton, they consist of three sliding rods of mahogany, each about four feet long, and divided into feet and hundredths. They carry each a circular sliding vane, having at the lower edge a square aperture, one side of which is levelled; and a line on the levelled side denotes the reading of the staff. The face of the vane is made of white holly, with an inlaid lozenge of ebony, forming at once a conspicuous object, and one easy of bisection. In levelling, the vane must be moved up or down till the horizontal wire of the telescope bisects the acute angle of the lozenge, as shown in the figure. As the line on the levelled edge at a denotes the reading of the staff, a piece equal in length to the distance $a\ b$ is cut off from the bottom of the staff, or, rather, the divisions commence at that number of inches above zero. (*Simms's Treatise on Mathematical Instruments*, 1834.)

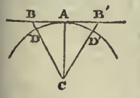


LEVELLING. A branch of surveying, which has for its object to discover how much any assigned point is higher than another assigned point above a level surface, or such a surface as water would assume when perfectly at rest.

In ordinary cases of levelling (for example, for canals, railroads, &c.) the instruments commonly employed are a spirit level attached to a telescope, and a pair of staves. (*See* Levelling Staves.) Suppose that the difference of level between A and B is to be found: the staves are placed successively at A, C, &c.; the intervals not exceeding 400 yards, on account of the curvature of the earth, and the levelling instrument placed between, at equal distances, to avoid corrections for refraction. It is then directed backwards to the first staff, A D, and next forward to the second, C E; and, at each observation, the division on the staff, or the height at which the visual ray meets it, is noted. The difference of the heights — that is, C E, A D — is the height of the higher station above the lower. The hindmost staff, and the levelling instrument, are now carried forward to a new position, and the back and fore observations repeated; and so on, till the operation is completed. Then the difference between the sum of the heights measured in the back observations, and the sum of the heights measured in the fore observations, will give the height of the one extreme station above the other.



But, in extensive surveys, it is often necessary to place the levelling staves at much greater distances from each other than 300 or 400 yards, in which case allowance must be made for the earth's curvature. Let D A D′ represent the arc of a great circle of the earth's surface, and A the place of an observer. All the points in this arc are in the same level; but the line of sight indicated by the level is a tangent to the circumference at A, and, consequently, objects B B′, in this line, will *appear* in the same level with A, though they are really elevated above it by the distances B D, B′ D′, intercepted on the radii between the arc and the tangent. Now, from the nature of the circle $AB^2 = BD\ (2\ CD + BD)$; but, in all cases of actual levelling, the arc A D is very small in comparison of the whole circumference, consequently the square of B D may be neglected, and the arc substituted for the tangent: we have then, for the value of B D, this expression, $BD = \frac{AD^2}{2\ CD}$; that is to say, the depression of the true level below the apparent level is equal to the square of the distance divided by twice the radius of the curvature of the earth. Supposing the diameter of the earth to be 7916 miles, and A D = 1 mile; we shall have B D equal to the 1-7916th of a mile, or 8·004 inches. At



the distance of 2 miles, the correction will be four times this quantity, or 32·016 inches; and so on, increasing as the square of the distance. It is most convenient to reckon both the distances and the corresponding depressions in feet and decimals of a foot; in which case the correction becomes $\frac{1}{7916 \times 5280} AD^2$, to be subtracted from the apparent or observed level, in order to obtain the true. The following table shows the depression in feet and decimals of a foot, for the different distances therein stated, the mean diameter of the earth being assumed = 7916 miles: —

Distance.	Depression.	Distance.	Depression.
Yards.	*Feet.*	*Miles.*	*Feet.*
100	0·00215	1	0·667
200	0·00861	2	2·669
300	0·01938	3	6·006
400	0·03445	4	10·677
500	0·05383	5	16·683
600	0·07752	6	24·024
700	0·10551	7	32·699
800	0·13781	8	42·709
900	0·17441	9	54·054
1000	0·21533	10	66·733
1100	0·26055	11	80·747
1200	0·31008	12	96·095
1300	0·36390	13	112·779
1400	0·42205	14	130·796
1500	0·48449	15	150·150
1600	0·55124	16	170·836

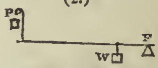
LE′VER. In Mechanics, an inflexible rod moveable about a *fulcrum* or prop, and having forces applied to two or more points in it. The lever is one of the mechanical powers; and, being the simplest of them all, was the first that was attempted to be explained. Its properties are treated of by Aristotle; but the first accurate explanation was given by Archimedes, in his Treatise *De Equiponderantibus*.

In treating of the lever, it is convenient to distinguish the forces applied to it by different names. One is usually called the *power*, the other the *weight* or *resistance*.

Levers are commonly divided into three kinds, according to the relative positions of the power, the weight, and the fulcrum. In a lever of the first kind (fig. 1.), the fulcrum F is between the power P and the weight W. In a lever of the second kind (fig. 2.), the weight W is between the fulcrum F and the power P. In a lever of the third kind (fig. 3.), the power P is between the fulcrum F and the weight W.

(1.)

(2.)



(3.)

The general principle of the lever is, that when the power and weight are in equilibrio, they are to each other inversely as their distances from the fulcrum. This property is almost an obvious consequence from the principle of virtual velocities; but it may be deduced from more familiar considerations. Let A B be a cylinder or bar of homogeneous matter. If supported from the middle, O, the two ends would evidently balance each other, and the pressure at O would be the same as if the whole matter of the bar were concentrated in that point. Suppose it to consist of two parts, A C and B C, these again would be separately supported at their middle points D and E; or the whole of the matter in A C may be conceived to be concentrated at D, and the whole of that in B C at E, and the equilibrium would not be disturbed. Hence the weight of A C attached at D, and the weight of B C attached at E, would balance the inflexible line D E, if supported at O, the centre of the whole bar A B. But $OD = AO - AD = \frac{1}{2}AB - \frac{1}{2}AC = \frac{1}{2}BC$; and $OE = OB - EB = \frac{1}{2}AB - \frac{1}{2}CB = \frac{1}{2}AC$; consequently, O D is to O E as B C to A C; or O D is to O E as the weight concentrated at E to the weight concentrated at D. This demonstration is commonly ascribed to Archimedes. (*Maclaurin's Account of Newton's Principia.*)

This proposition shows the advantage obtained by using the lever as a mechanical engine. The arm P F (fig. 1.) is commonly longer than W F, and, consequently, when there is equilibrium the weight exceeds the power. The proportion in which the weight exceeds the power is called the *mechanical advantage*, or purchase. Suppose P F (figs. 1. and 2.) = 4 feet, and W F = 1 foot; then a power of 1 lb. acting at P will overcome a resistance of 4 lbs. at W.

Suppose the lever with the weights P and W to turn round the fulcrum, the two points to which P and W are attached will describe arcs proportional to the radii F P, F W; consequently the power P is to the weight W as the velocity of the weight to the velocity of the power.

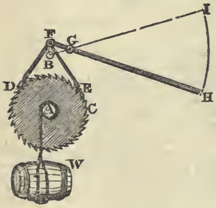
Therefore in this, as in all mechanical engines, when a small power raises a great weight the velocity of the power is much greater than the velocity of the weight; and what is gained in force is therefore said to be lost in time.

When the power and the weight do not act on the lever in directions perpendicular to its length, or when the arms of the lever are not in the same straight line, or are bent, then the power and the weight are not to each other reciprocally as the arms of the lever, but as the straight lines drawn from the fulcrum perpendicular to the respective directions in which the power and the weight take effect.

Examples of the application of the lever are of constant occurrence in the mechanical arts. The crowbar, the handspike, the poker, scissars, nippers, pincers, &c., are levers of the first kind; the toothed hammer is only a bent lever of this kind. The second kind includes the chipping knife, nutcrackers, the common door, oars and rudders, the wheelbarrow, &c. To levers of the third kind belong the sheep-shears, the treddle of the turning lathe, tongs, &c.: these have a mechanical disadvantage, but admit of a proportionally wider motion. The bones of animals are generally levers of this sort. The socket of the bone is the fulcrum; a strong muscle attached to it near the socket is the power; and the weight of the limb, with whatever resistance is opposed to its motion, is the weight. A very moderate contraction of the muscle thus gives considerable motion to the limb.

From the principle of the lever is deduced the distribution of pressure in the case of a pole bearing an intermediate weight. If the weight hang from the middle, the carriers will share the burden alike; but if a load is laid over the pole, and a vertical from its centre of gravity divides the length unequally, as will be the case on altering the inclination of the pole (for example, in climbing a hill), then the bearer nearest to whom the vertical falls suffers a greater strain than the other.

Universal Lever is the name given to a machine formed of a combination of the lever with the wheel and axle, the object of which is to give a continued rectilinear motion to a heavy body by means of the reciprocating motion of the lever. F G H is a straight line, whose centre of motion is at G. At the extremity of its shorter arm hang two bars, the former of which has a hook to catch into the teeth of the wheel A C D, while the latter has its end bent in order to slide over the outer parts of those teeth. The axle A has a cord wound round it, to the end of which is attached the weight W. Now suppose the end H of the lever to be raised from H to I, while the other end descends from F to B; the bar F E will then push the tooth E of the wheel to C, while the hook D slides over an equal space on the other side of the wheel. On bringing down again the end of the lever from I to H, the other extremity ascends through B F, and the hook D raises up the left-hand side of the wheel through a space equal to E C. Thus the reciprocating motion of the lever is made to communicate a continued rotatory motion to the wheel, and, consequently, to lift the weight W suspended from its axle by the cord. The universal lever has long been employed in saw-mills, for the purpose of drawing along the logs to the saw. (*Gregory's Mechanics*, vol. ii.)



LEVI'ATHAN. The name of a great marine animal in the Book of Job, described in chapter xli., which was covered with close-joined or confluent scales, and had the jaws, or "doors of the face," armed with terrible teeth round about. Some naturalists have supposed that the crocodile might be the subject of the sacred poet's allusions; but the "breath that kindleth coals" could scarcely be suggested by the respiratory actions of a cold-blooded reptile. The same objection applies to the opinion that the leviathan of Job was the extinct megalosaurus: with this additional difficulty, that the megalosaurus was a terrestrial reptile, as the large medullary cavities of its bones prove; while of the leviathan it is said that "He maketh the deep to boil like a pot; he maketh the sea like a pot of ointment: he maketh a path to shine after him; one would think the deep to be hoary. Upon earth there is not his like." These expressions accord well with the violent and impetuous exertions of a huge cetacean in his native element; and the verse, "Out of his nostrils goeth smoke, as out of a seething-pot or cauldron," does not inaptly figure the "blowing" of a whale. The teeth of either the cachalot or grampus might well be termed terrible; and their external epidermic covering, if considered as analogous to the scales of fishes, would have its distinguishing peculiarities correctly defined by the following expressions:—"His scales are his pride, shut up together as with a close seal. One is so near another, that no air can come between them. They are joined one to another, *they stick together, they cannot be sundered.*" (Verses 15, 16, 17.) Many persons must have witnessed the phenomena of the luminosity of the sea on our own coasts, where it is usually feeble in comparison with that produced in the warmer latitudes of the Mediterranean, or in the tropics. The phenomena which naturalists and voyagers have described as being produced by the swimming and blowing of the cetaceous animals in a phosphorescent ocean, during the night, might likewise have suggested the description of the fire and sparks that escape from the mouth of the leviathan, and of the shining path that he leaves behind him in the deep.

LEVIGA'TION. (Lat. lævus, *smooth.*) The process of reducing substances to a state of fine mechanical division, by mixing them, previously powdered, with water or some other fluid, and rubbing the paste upon a hard smooth slab, with the flat face of a stone called the muller. The paste is then often stirred into a large vessel of water, where the coarser powder first falls, and the finer remains suspended, and is afterwards collected by pouring it off with the water, and suffering it slowly to subside. In this way, by repeated subsidences, powders of very different degrees of fineness are obtained.

LE'VITES. The descendants of Levi, one of the twelve sons of Jacob, to whom no distinct territory was allotted in the land of Canaan, as to the other tribes; but who were set apart for the ministration of the religious services throughout the country, and had forty cities, situated in various parts of Palestine, peculiarly appropriated to their residence. The law of Moses commanded the tenth of the vegetable produce of the land, and also of the cattle, to be given to them; of this a tenth was set apart for the priests, whose assistants the Levites were. When God destroyed the first-born of the Egyptians, he appointed that the first-born males of the Israelites should be "set apart unto himself" (Exod. xiii.), in commemoration of the immunity from that visitation which was vouchsafed to the chosen people. Afterwards it is recorded that, upon the sons of Levi discovering an extraordinary zeal against idolatry, in the case of the golden calf (Exod. xxxii.), the religious offices of the first-born were assigned as an honourable privilege to that tribe. The priests were confined to the family of Aaron, who, with Moses his brother, were both of the tribe of Levi. For the classes of which the Levites were composed, their offices, privileges, &c., see particularly Numb. iii. iv. viii.; also 1 Chron. xxiii.—xxvi.

LE'VYNE (so called from Levy, the crystallographer). A crystallized mineral found in Ireland, Faroe, and elsewhere, closely allied to the zeolites. It is a hydrated alumino-silicate of lime and soda.

LEXICO'LOGY, or LEXIGOGRAPHY. (Gr. λεξις, *a word or phrase*, and λογος, *description.*) A word used by some writers to express that branch of philology which treats of words alone, independently of their grammatical and rhetorical uses; considering their senses, their composition, and their etymology. (*See* PHILOLOGY.) There are two useful papers in the *Quarterly Review* on Greek lexicography, vols. xxii. xliv.

LE'XICON. (Gr. λεξις.) A dictionary of words, or vocabulary; originally, and still usually, confined to dictionaries of the Greek or Hebrew tongues. The oldest Greek lexicon is the *Onomasticon*, which was written 180 years before Christ; the oldest Hebrew lexicon belongs to the 9th century. *See* DICTIONARY.

LEYDEN JAR. *See* ELECTRICITY.

LEZE-MAJESTY. In Jurisprudence, any crime committed against the sovereign power in a state. The name is derived from the Roman phrase, "crimen læsæ majestatis," which denoted a charge brought against a citizen for acts of rebellion, usurpation of office, and general misdemeanours of a political character, which were comprehended under the title of injuries to the "majesty of the Roman people." The emperors transferred to all offences against themselves the same criminal character; and offences of leze-majesty were multiplied under their arbitrary governments.

LI'AS. A provincial name, adopted by geologists, for an argillaceous limestone, which, together with its associated beds, is characterized by peculiar fossils. *See* GEOLOGY.

LIBA'TION. (Lat. libo, *I pour.*) The solemn pouring of wine and other liquids in the religious ceremonies of antiquity; in Greek σπενδειν. Libation appears (if our translation is correct) to have been used in the earliest recorded sacrifice; for Abel offered milk (Gen. iv. 4.): a daily libation of water was used by the Jews in the Feast of Tabernacles; the burnt offering instituted by Moses was of wine. (Numb. vi. 7.) The Grecian libations, in like manner, were of unmixed wine; but sacrifices to nymphs, Ceres, Proserpine, and some other deities, were attended by libations of oil and wine, &c.

The wine was poured between the horns of victims, on the altar or on the ground. The ancients had also a well-known custom of pouring out a small quantity of wine, by way of libation to the gods, at the commencement of their banquets; and libation for the emperors became common under imperial Rome. (See this art. in the *Enc. Met.*)

Te multa prece, te prosequitur mero
Defuso pateris. HORACE.

LIBA'VIUS'S FUMING LIQUOR. Bichloride of tin, obtained by distilling a mixture of 1 part of tin filings with 3 of corrosive sublimate. It emits dense white vapours when exposed to air.

LI'BEL. In the Spiritual Courts, the original declaration in a civil action is so termed. *See* LAW, ECCLESIASTICAL.

LIBEL, in Law, signifies almost any malicious publication by writing or printing, or by signs, pictures, &c. Whatever tends to render a man odious or ridiculous, or to lower him in the esteem and opinion of the world, is a libel; and may either be made the subject of a civil action for compensation in damages to the individual injured, or, as having a tendency to excite his wrath, and provoke a breach of the peace, may be proceeded against by indictment or criminal information. Where it is sought to make a party responsible in damages for a libellous publication, he may set up the truth of it as an answer to the complaint; for the plaintiff, if really guilty of the misconduct or other thing imputed to him, is not considered to suffer by its disclosure any private injury which can be a legitimate ground of compensation to him; but, when the proceeding is by criminal prosecution, the truth is no defence whatever, as being altogether immaterial; for the libellous matter may equally provoke a breach of the peace, whether it be true or false. The court, however, will, in general, before granting a rule for a criminal information, which supersedes the usual practice of a presentment by the grand jury, require the prosecutor to deny on affidavit the truth of the matters charged against him. It will be seen, however, that there is not in any case a legal foundation for the maxim vulgarly ascribed to the law, "The greater the truth the greater the libel." All publications are libels, and criminally punishable as such, which have a tendency to disturb the public peace, his majesty's government, the established religion, public morals, or the administration of justice. Before the 32 Geo. 3. c. 60. (Fox's Act), on a criminal trial for libel the jury were not allowed to take the whole question into consideration, and return a general verdict of guilty or not guilty; but could only decide upon the fact of publication, and whether the libel meant that which it was alleged in the indictment to mean; the court alone taking upon itself to determine the criminality or innocence of such meaning. Now, however, in libel, as previously in all other criminal cases, it is competent to the jury to apply their judgment to the whole question, and return a general verdict of guilty or not guilty.

Libel is deemed in law a greater offence than slander, inasmuch as written defamation is commonly the result of more deliberate malice than that which is merely spoken, and frequently inflicts more extensive and permanent injury on the object of its attack. Many words, such as "rogue," "swindler," which are not actionable when spoken, are so when written.

Libel may almost always be made the subject of an indictment, although slander seldom can; and, in an action for libel, a verdict for a farthing damages formerly gave the plaintiff his full costs, until the recent Act of Lord Denman; whereas, in slander, if the damages are found under forty shillings, the plaintiff is entitled to no more costs than damages.

LIBE'LLULINES. A genus of Neuropterous insects, of which the dragon-fly, *Libellula*, is the type.

LI'BER. (Lat. *bark.*) In Botany, the interior lining of the bark of Exogenous plants. It consists of woody tissue in great quantity, and very thick-sided, intermixed with cellular tissue. It appears to be formed annually, at the same time as the concentric zones of wood, and is intended by nature to convey downwards the secretions elaborated in the bark and leaves. It is the principal seat of laticiferous vessels.

LIBER. In Roman Mythology, a surname of Bacchus, in reference, perhaps, to the idea of his being a liberator or deliverer. Liber was originally an old divinity, who presided over fertility; and who was worshipped in connexion with Libera (a name of Proserpine, according to Cicero, *De Natura Deorum*) and Ceres.

LI'BERAL. In Politics, a cant name, which has been applied since 1815 to the party in each country which advocates constitutional institutions where they do not exist, or their extension into a more popular character where they do. As a party name, this word has been most definitely adopted in Spain, where the party of the cortes assumed the title of *liberales*, and nicknamed their adversaries by that of *serviles*.

LIBERA'LIA. A sacred festival, with games; so called from Liber, a Latin name of Bacchus, in honour of which god they were celebrated at Rome. It was on occasion of this festival that the Roman youths who had attained the age of seventeen assumed the manly dress, or *toga*.

LIBE'RTAS, in the mythology of the Greeks and Romans, was a goddess worshipped with peculiar veneration. By the former she was invoked by the synonymous title Eleutheria; and throughout all parts, both of Greece and Italy, statues, temples, and altars were erected in honour of her. At Rome, her most famous temple, built by T. Gracchus, was situated on the Aventine Mount. She was represented under the figure of a woman, holding in one hand a cap, the symbol of Liberty, and two poniards in the other. In modern times a cap is also used as a symbol of Liberty: thus, in France a red cap formed the badge of the Jacobin club. In England a blue cap with a white border is used as a symbol of the constitutional freedom of the nation, and Britannia sometimes bears it on the point of her spear.

LI'BERTINES. In Church History, a name given, in England, to the early Anabaptists, about the middle of the 16th century. (*Mosheim*, vol. iv. p. 430., transl., ed. 1790.) *See* ANABAPTISTS.

LI'BERTY. In Philosophy. *See* NECESSITY.

LIBITI'NA. An Italian goddess, patroness of funerals and undertakers; synonymous with the Venus Infera or Epithambia of the Greeks. She had a temple at Rome, in which was deposited a small coin, called Libitinai ratio, for every person who died. This custom, which originated in the desire of the Roman authorities to procure a faithful account of the number of deaths, may, perhaps, be regarded as among the first attempts to obtain an accurate census of the population.

LI'BRA. (Lat. *the balance.*) One of the zodiacal constellations, the seventh in order, beginning with Aries. Libra is one of the forty-eight ancient constellations of Ptolemy.

LIBRA denotes also the ancient Roman pound. *See* WEIGHTS.

LIBRARIES, ITINERATING. The name given to a peculiar species of circulating library, instituted a few years ago at Haddington, in Scotland, by Mr. Samuel Brown. The principle on which such libraries are formed consists, as the epithet *itinerating* implies, in the books being sent from one part or district of a country to another on the following plan: — The books are formed into divisions, consisting each of a certain number of volumes, and proportioned in number to the extent of the country intended to be supplied. Each division remains for a certain period (in some instances one or two years) in the same place, when it is removed to another locality, and succeeded by a new supply of books of the same number; by which means each locality has a fresh supply of useful reading at short stated intervals. In Haddingtonshire, which may be called the head-quarters of itinerating libraries, the books consist of 43 divisions of 50 volumes each; and on the principle above explained each volume, at an average of the 43 divisions, is read *five* times during two years, the period at which the books are changed. The system of itinerating libraries has been extended to various other parts of Scotland, to several districts of England, to Ireland, Canada, South Africa, and Jamaica. The use of the books is gratuitous, if so wished; and never more than 1*d.* per annum has been systematically taken from any reader. Voluntary contributions, however, either in books or money, are received. (See *Geo. Dict.*, art. "Haddington.")

LI'BRARY. (Lat. liber, *book.*) The name given either to a collection of books, or to the apartment or edifice in which they are kept. The oldest public library of antiquity, of which we have any credible account, is that founded by Pisistratus at Athens, which was carried by Xerxes into Persia, and recovered by Seleucus Nicanor. Whether this was the same library which Sylla (according to Plutarch) carried to Rome, and which was again restored by Hadrian, is not clear; nor is its ultimate destiny known. According to a well-known tradition, the Goths, when masters of Athens, refused to burn the public libraries, which contributed to the effeminacy of its citizens. The library of Alexandria was the most famous of antiquity. Its history has been written by Bonamy (*Mem. de l'Ac. des Inscr.* vol. ix.), Reinhard (Gotting. 1792), and many others. It was first formed by the Ptolemies. Soter, Lagides, Philadelphus, and Euergetes: the last of whom resorted to very royal measures for the accomplishment of so laudable an end; for he is said to have seized on books imported from Greece, caused them to be copied, and returned the copies to the proprietors, keeping the original for his library. The collection of Soter is said to have been deposited in a suburb called Bruchium, which was burnt by the troops in Cæsar's Egyptian war. That of Philadelphus (the smaller of the two) was preserved in the temple of Serapis, and became the nucleus of the later library, which was augmented by the great library of Pergamus (said to have amounted to 200,000 volumes), presented to it by Mark Antony. The

narrative of the destruction of this library by the fanatical Arabs, in A.D. 641, is among the popular chapters of history; and the most careful inquirers are of opinion that it is substantially, if not literally, true, notwithstanding the doubts thrown on it by Gibbon and others. The first public library at Rome was founded by Asinius Pollio, A.D. 716; the second, the Palatine, by Augustus, in 726: great part of it was consumed under Commodus; but much remained even in the time of Constantine. Reusch (1734), Eckerman (1764), and Eckhart (1799), have published separate dissertations on the libraries of the Romans. The ancient libraries of the West must have wholly perished in the convulsions which attended the overthrow of its empire. The history of those of the east is not easy to investigate. Constantinople certainly possessed, at the period of its capture, extensive remains of ancient literature; and many, but almost wholly fruitless investigations, have been made of late years in the monastic libraries of modern Greece, particularly of Mount Athos, for valuable manuscripts. (See *Walpole's Oriental Memoirs; Journal of Education*, vol. ii.) The best accounts of ancient libraries, to which we are able to refer the reader, are contained in the work of Petit Radel, *Récherches sur les Bibliothèques Anciennes et Modernes*; Heeren, *History of the Study of Classical Literature*, vol. i.; *Ersch and Gruber's Encyclopedia*, art. "Bibliotheken;" *Taylor's History of the Transmission of ancient Books in modern Times; Enc. Brit.*, Suppl., "Library."

Of modern public libraries, the greatest and most celebrated is that of Paris (Bibl. Royale). It was commenced by King John, in the middle of the 14th century, with *ten* volumes; and has been augmented by subsequent kings to the enormous number it now possesses. (Le Prince, *Essai Historique sur la Bibl. du Roi*, Paris, 1787.) Next to that of Paris in extent, and possibly in value, are the libraries of St. Petersburg and Munich. In Italy, the Ambrosian at Milan, and the Vatican at Rome, are peculiarly rich in MSS. Of British libraries, the greatest are those of the British Museum; of the two English universities, of which that of Oxford (the Bodleian) is peculiarly rich in oriental manuscripts; that of the Advocates, at Edinburgh; and of Trinity College, Dublin. Statements of the number of books contained in public libraries will be found in many works; but no statistical information is more imperfect and worthless. Some have not scrupled to say that there is no information respecting the great foreign libraries, as to the number of printed books, which can be relied upon within one half. Such scepticism may be exaggerated; but that there is some ground for it may be conjectured from the following comparison, which we have made between different statements. That of M. Panizzi is contained in the Appendix to the Report on the Brit. Mus., 1838, vol. ii. No. 6. The "Returns" are those furnished by official persons to inquiries addressed on the same occasion, and will be found in the same work. We should premise that the number of printed books belonging to the library of the Brit. Mus. was actually returned in 1833 at 218,937, and is now probably 260,000; *volumes* of MSS. in 1833, 21,900.

LIBRA'TION. (Lat. libra, *a balance*.) In Astronomy, a term applied to certain phenomena resulting from the moon's motion, whereby the spots very near the border of the lunar disc alternately disappear and become visible, making stated periodical oscillations, and indicating, as it were, a sort of vibratory motion of the lunar globe.

The libration is of three kinds; the libration in longitude, the libration in latitude, and the diurnal libration. The libration in longitude is occasioned by this circumstance, that the rotatory motion of the moon about her axis is not always precisely equal to the angular velocity in her orbit. If the moon's orbital motion were uniform, and performed in the same time as her rotation about the axis, the radius vector from the centre of the earth would always intersect the lunar disc in the same point, or the moon would always present exactly the same face to the earth. But the rotatory motion is sensibly uniform; while the orbital motion, being performed in an ellipse, is sometimes slower and sometimes faster than its average amount. Hence the spots near the eastern and western borders alternately disappear and reappear.

The libration in latitude is occasioned by the inclination of the moon's axis of rotation to the plane of her orbit. Supposing this axis always to have the same direction in space, the angle which it makes with the radius vector of her orbit will be acute during one part of her revolution and obtuse in another. Hence the two poles of rotation, and the adjacent parts of the surface, are alternately visible from the earth.

The diurnal libration is simply a consequence of the lunar parallax. The observer, being placed at the surface of the earth, perceives points on the moon's disc at the time of her rising, which disappear as her elevation is increased; while new ones on the opposite border, that were before invisible, come into view as she descends towards the horizon. *See* Moon.

The libration in latitude and diurnal vibration were discovered by Galileo. Hevelius first observed and explained the libration in longitude.

LI'CENCE. (Lat. licet, *it is lawful*.) In Law, a power or authority given to a man to do some lawful act, and may be by word or by deed. If a party give licence to another to do acts on his ground, which without that licence would be trespass, and the party abuses his licence, he becomes a trespasser *ab initio*. Licence is also commonly taken for the admission of an individual, by proper authority, to the right of doing particular acts, practising in professions, &c., and for the certificate of such admission.

LICE'NTIATE. A degree in some foreign universities; but not known in the universities of England, except in the instance of the degree of licentiate in medicine, which is granted at Cambridge. In the original sense of the word it appears to have been only a title applied to such as had obtained a licence to teach. It is said to be of Italian origin, and first granted at the university of Bologna. Where the degree of licentiate exists, it intervenes between that of bachelor and that of doctor.

LI'CHEN. (Gr. λειχην, *a roughness of the skin*.) In Pathology, a papulous eruption of the skin, terminating in scurfy exfoliations: it is generally symptomatic of disordered stomach and bowels.

LICHE'NIC ACID. The acid peculiar to some species of lichens. It appears to be the *malic acid*.

LI'CHENIN. A substance closely allied to starch, extracted from the *Cetraria islandica*, or Iceland moss.

LI'CHENS. Plants of a very low organization, which grow on the bark of trees or rocks, when they form a kind of incrustation; or upon the ground, when they consist of irregular lobes parallel with the earth's surface. Occasionally in all situations they are found in a branched state; but their subdivisions are generally irregular and without order. Their fructification consists of hard nuclei, called *shields*, which break through the upper surface of the *thallus* or main substance of the lichen, are of a peculiar colour and texture, and contain the reproductive particles. Lichens abound in the cold and temperate parts of the world. The greater part are of no known use; but some, as the reindeer moss (*Cenomyce rangiferina*), the Iceland moss (*Cetraria islandica*), and various species of *Gyrophora*, are capable of sustaining life, either in animals or man. The Iceland moss, when deprived of its bitterness by boiling, becomes indeed a diet recommended to invalids. Others are used as tonic medicines, as *Variolaria faginea*, and *Parmelia parietina*. There principal use is, however, that of furnishing the dyer with brilliant colours; orchall, cudbear, and perolle, with many more, are thus employed.

LICKS. A term applied in North America to sandy tracts of land, upon which common salt forms an efflorescence, and which almost all graminivorous animals resort to for the purpose of licking the surface.

LI'CTORS. (Lat. ligo, *I bind*.) Officers whose duty it was to attend the principal Roman magistrates (such as the consuls, master of the horse, and prætors) and the vestal virgins on their appearance in public, and to act as constables under their command. Their insignia were the *fasces* or bunch of rods (originally encircling an axe, which was removed by Publicola, used under the republic only by dictators, and restored under the emperor), and the *virga* or rod, which was used to touch the door of the magistrate on returning home. The number of lictors in attendance varied according to the rank of the magistrate; thus the consuls had twelve, the prætors six, and dictators, according to some, twenty-four.

LIEGE. In the Latin of the middle ages *ligeus*, from *ligare*, to bind. A liege lord, in feudal language, is a superior to whom *allegiance* is owed, and a *liege-man* he who owes such allegiance. Hence all subjects are termed *lieges* of the king. Some writers derive the word liege from the Teutonic word *leude* (modern German *leute*, people), which was used in the sense of *vassal*.

LI'EN. (Fr. lien, *bond*.) In Law, signifies the right which a creditor has to retain the property of his debtor until the debt has been paid; and furnishes one of very few instances in which a party is allowed to take the law, as it were, into his own hands. Liens are either general or particular. A general lien is the right to retain a thing for a general balance of accounts, and not for those demands only which arise in respect of the thing retained. This sort of lien is said not to be favoured by law. A particular lien, which the law is said to favour, is a right to retain a thing when the claim against the owner of it arises out of the thing retained itself; as, where a tailor has made the cloth of his customer into a coat, the tailor is allowed to retain the cloth until he is paid for his labour in making it into a coat. The payment of a simple contract debt cannot be enforced by action after six years have elapsed from the time the debt was incurred; but a party who has a lien on property may retain it for an unlimited period, until his claim has been satisfied.

LIE-TO. *See* LYE-TO.

LIEUTE'NANT. (Fr.) An officer, who, as the derivation of the word implies, supplies the place and discharges the duty of a superior in his absence.

LIEUTENANT IN THE ARMY. The officer immediately subordinate to the captain, in whose absence he takes the command of his company. In the British service the lieutenants of the Life Guards and Horse Guards, and of the three regiments of Foot Guards, have the rank of captain. In the artillery, engineers, marines, and rifle brigade, of the British service, and in all the regiments of most of the Continental nations, there being no cornets or ensigns, the subaltern officers are distinguished as first and second lieutenants. The pay of a lieutenant varies, according to the regiment or branch of the service to which he belongs, from 10*s*. 4*d*. to 6*s*. 6*d*.; and the price of his commission, according to the present regulations, is, for the Life Guards, 1785*l*.; Horse Guards, 1600*l*.; Cavalry, 1190*l*.; Foot Guards, 2050*l*.; Infantry, 700*l*.

LIEUTENANT IN THE NAVY. The next rank to that of commander, and co-ordinate with that of captain in the army. The number of lieutenants appointed to ships of war varies with their rate. A ship of the first rate carries eight lieutenants, besides supernumeraries; and those of the second, third, fourth rates, &c. have respectively one less than the number appointed to the preceding rate. The monthly pay of a lieutenant in the British navy varies, according to the ship and his duration of service, from 11*l*. 10*s*. to 9*l*. 4*s*.

LIEUTE'NANT-GENERAL OF THE KINGDOM. A dignity equivalent to that of regent, which has been occasionally held in France on temporary emergencies. The Count d'Artois (afterwards Charles X.) took this title in 1814 on entering France, and held it until the arrival of his brother, Louis XVIII. On the expulsion of Charles X., in 1830, the Duke of Orleans was constituted lieutenant-general, both by an ordinance of that prince, and by the provisory government of the Hotel de Ville, on July 29.; and retained the title until he was proclaimed king, on the 7th August following.

LIFE ANNUITY. *See* ANNUITY.

LIFE ASSURANCE. *See* ASSURANCE.

LIFE BOAT. A boat originally made at Shields, in 1789, by Mr. Greathead, for saving the crews of shipwrecked vessels. The following are the general principles: — The boat is wide and shallow; the head and stern are alike, for pulling in either direction, and raised, to meet the waves; it pulls double-banked, the oars being fir, for lightness, and fitted with thole pins and grummets, and is steered with an oar. The boat is cased round inside, on the upper part, with cork, in order to secure her buoyancy with as many persons as she can carry, even though full of water; the cork likewise assists in maintaining, or, if overset, in recovering, the position of stable equilibrium. The boat is painted white, to be conspicuous in emerging from the hollow of the sea. It is a curious fact that the smugglers paint their boats white for the contrary reason, because dark-coloured objects alone are discernible in dark nights.

LIFE BUOY. A buoy, with a mast to render it conspicuous, thrown into the sea upon a man's falling overboard. The life buoy invented by Lieut. Cooke, R. N., is furnished with a composition which is fired by the act of disengaging the buoy from its place, at night, and burns with a strong light.

LIFE GUARDS. The cavalry troops composing the body guard of a sovereign prince are so called. In England they consist of two regiments, comprising each 32 officers, 53 non-commissioned officers, and 351 privates. In Germany such troops are styled the *leib garde* (body guard); and in France the *garde du corps*. *See* GUARDS.

LIFE LINE. In a Ship, any rope stretched along for the safety of the men, as is practised in bad weather.

LIFE, MEAN DURATION OF. *See* EXPECTATION OF LIFE.

LIFE RENT. In Scottish Law, the right of enjoyment, either of an heritage or a sum of money, for the life of the life-renter. The superior proprietor of the subject, or *fee*, in which this rent subsists, is termed the fiar. *Terce* (*i. e.* dower) and *courtesy* (analogous to the courtesy of England in English law) are instances of legal life-rents.

LIFTING PUMP. *See* PUMP.

LIFTS. The ropes which support the ends of yards or booms against the weight of the men upon them.

LI'GAMENTS. (Lat. ligo, *I bind*.) Strong elastic membranes connecting the extremities of the moveable bones. When boiled in water they yield more or less gelatine, and leave a portion of insoluble albumen.

LI'GATURE. (Lat. ligo.) In Music, the tie which binds several notes of like length together, by which they appear in groups. Thus  four quavers, by means of a ligature at top or bottom, assume the form , the line connecting them being the ligature.

LIGHT. (Germ. licht.) The cause of those sensations which we refer to the eyes, or that which produces the sense of seeing. The phenomena of light and vision have always been regarded as one of the most interesting branches of natural science; though it is only since the days of Newton that they have been examined with such care as to afford grounds for any safe speculation respecting the nature of light, and the mode of its propagation through space. But the solution of these two questions is involved in very great difficulty; for notwithstanding the splendid discoveries of that immortal philosopher, and the long train of interesting and important facts which have been investigated since his time, and more particularly since the beginning of the present century, the true theory of light still remains an enigma. This does not arise from any difficulty there is in framing an hypothesis which shall afford a mechanical explanation of the various phenomena, but from the circumstance that more hypotheses than one have been imagined by which all the phenomena can be explained, not merely in a general way, but with the precision of numerical calculation.

The knowledge of the laws which regulate the phenomena of light constitutes the science of *Optics*, which is divided into a number of subordinate branches. An account of the principal phenomena will be found under the terms ABERRATION, CHROMATICS, INTERFERENCE, OPTICS, POLARIZATION, REFLECTION, REFRACTION, &c. The present article will be confined to a brief enumeration of some of the principal properties of light, and a statement of the two rival theories by which modern philosophers explain its nature and propagation.

Properties of Light. — Experiments of the simplest and most familiar kind suffice to show that light is propagated from luminous bodies in all directions. Provided nothing intervenes to intercept the light, they are seen in all situations of the eye. Thus, the flame of a lamp is visible from every part of the sphere of which it occupies the centre; and the same is the case with respect to a phosphorescent body, an electric spark, a ball heated red-hot, or light having any other source. The sun throws its light, not only on the earth, but on the planets, and comets, and every other body in the firmament.

Another property of light is, that in a homogeneous medium it is always propagated in straight lines. This is evident from various considerations. The forms of shadows correctly represent the outlines of the objects which produce them, as seen from the luminous body, which could not be unless the light proceeded in straight lines from the extremities of the objects to the borders of the shadow. If three plates of metal, each pierced with a small hole, are placed at some distance behind each other, and in such positions that the three holes are exactly in one straight line, the light will pass freely through them; but if the holes are not exactly in a straight line, no light will pass. In like manner, if a number of similar objects are placed behind each other in a straight line, the first renders all the others invisible to an eye placed in the same line. We cannot see through a bent tube.

A third property of light is that it requires time for its propagation. The velocity with which it passes from one point to another is, however, so great, that, with respect to any terrestrial distances, the passage may be considered as instantaneous. But astronomy furnishes the means, not only of detecting its propagation, but of measuring its velocity with great precision. The eclipses and emersions of Jupiter's satellites become visible about 16 min. 26 sec. earlier when the earth is at its least distance from Jupiter, than when it is at its greatest. Light, therefore, occupies above a quarter of an hour in passing

through the diameter of the earth's orbit. Now, the sun's distance from the earth being nearly 95,000,000 of miles, it follows that light must travel through space with the prodigious, though finite, velocity of 192,500, or nearly 200,000 miles, in a second of time, and consequently would pass round the earth in the eighth part of a second. Astounding as this conclusion is, no result of science rests on more certain evidence. It is also proved, by the phenomena of aberration, that the light of the sun, planets, and all the fixed stars, travels with one and the same velocity.

When light in its progress encounters an obstacle, or enters a different medium, it undergoes certain modifications, depending on the nature of the body on which it falls, or the medium into which it enters. When it falls on a smooth polished surface, a portion of it is regularly reflected; that is to say, it is returned from the surface at an angle equal to the angle of incidence, and pursues its course in a straight line as before the reflection. The quantity of light thus reflected depends on the nature and polish of the surface, and on the angle of incidence, being greatest when that angle is small; but it is calculated that even the brightest and most opaque surfaces, mercury for example, do not reflect more than three fourths of the incident light. Another portion of it enters the medium, and there (if the medium is homogeneous) pursues a rectilinear course, but differing from its former direction. In this case it is said to be refracted. The angle of refraction depends on the nature of the medium, each different medium having its own peculiar law of action on light. In many media, comprehending the liquids and most of the uncrystallized substances, the whole of the refracted light is bent from its original direction at the same angle. In many others, as in most crystallized media, part of the refracted light follows one course, and another part of it a different one; the two portions acquiring at the same time different physical properties. In this case the refraction is said to be double. A third portion of the light falling on a body is neither reflected nor refracted regularly, but is scattered in all directions; and it is this portion which renders bodies visible. All bodies on which light falls absorb a certain part of it; more or less in proportion to their opacity. In perfectly opake bodies the absorption is total, and the light does not penetrate to a sensible depth under the surface. In others it penetrates farther; but even in the most transparent it is gradually stifled and lost. A depth of only seven feet of pure water is required to extinguish one half of the incident light. *See* Reflexion.

Solar light, refracted by a prism or other body, is separated into a multitude of rays of different colours, each of which afterwards proceeds in its course independently of all the others. These differently coloured rays possess different physical properties, and different degrees of refrangibility. It is to this dispersion or separation of light by refraction that we owe all the pleasure derived from the variegated hues of natural bodies. The investigation of the laws of the dispersion of the coloured rays forms the subject of *chromatics*. One of the principal facts connected with it is, that the dispersion of the rays by different refracting substances is not proportioned to the refraction; the dispersive power of some substances being greater than that of others, while their refracting power is less. This fact led to the important discovery of the *achromatic telescope*. *See* Achromatic, Chromatics.

Light, on being regularly reflected or refracted, undergoes a modification termed *polarization*, in virtue of which it presents, on encountering another medium, different phenomena of reflection and refraction from those presented by light which has not undergone such modification. When a ray of light, having acquired this modification, is made to fall on a plane reflecting surface under a certain angle of incidence, no portion of it will be reflected; the whole is transmitted or absorbed. But, in the case of ordinary light, some portion is always reflected from a polished surface, whatever be the angle of incidence; the light has therefore acquired the property of being acted upon in a particular way; whence Malus, who first investigated this subject in a philosophical manner, gave the phenomena the name of *polarization*, from its analogy to the effect produced by a magnet on a series of needles. *See* Polarization.

The last property of light which we shall notice, as important towards forming a theory of its propagation, is that to which Dr. Young gave the name of *interference*. Under certain circumstances, the rays of light exercise a mutual influence on each other; increasing, diminishing, or modifying each other's effects according to certain laws. This mutual action of the rays on each other gives rise to a great number of the most intricate phenomena of optics, and affords a sufficiently simple explanation of them, in numerous cases where no other explanation has yet been found on other hypotheses. The phenomenon is described under the term Interference.

Theories of Light. — Two different theories have long divided the opinion of philosophers respecting the nature and propagation of light. One of these consists in supposing it to be composed of particles of excessive minuteness, projected from the luminous body with a velocity equal to nearly 200,000 miles in a second. This hypothesis was adopted by Newton, and, till recently, has been acquiesced in by the greater number of writers on optics. The other hypothesis supposes light to be produced by the vibrations or undulations of an ethereal fluid of great elasticity, which pervades all space and penetrates all substances, and to which the luminous body gives an impulse which is propagated with inconceivable rapidity, in spherical superficies, by a sort of tremor or undulation, as sound is conveyed through the atmosphere, or a wave along the surface of water. Both of these hypotheses are rendered probable by the great number of phenomena of which they afford a mechanical explanation; but they are both, also, attended with very great difficulties. Other theories have also been proposed; but they have not met with such general attention from philosophers as to make it necessary to explain them in this place.

Corpuscular Theory of Light. — Sir John Herschel, in his admirable *Essay on Light* in the *Encyclopædia Metropolitana*, states the principles of the Newtonian or Corpuscular theory as follows: —

1. "That light consists of particles of matter possessed of inertia, and endowed with attractive and repulsive forces, and projected or emitted from all luminous bodies with nearly the same velocity, — about 200,000 miles per second.

2. "That these particles differ from each other by the intensity of the attractive and repulsive forces which reside in them; and in their relations to the material world; and also in their actual masses, or inertia.

3. "That these particles, impinging on the retina, stimulate and excite vision; the particles whose inertia is greatest producing the sensation of red, those of the least inertia of violet, and those in which it is intermediate the intermediate colours.

4. "That the molecules of material bodies and those of light exert a mutual action on each other, which consists in attraction and repulsion, according to some law or function of the distance between them; that this law is such as to admit, perhaps, of several alternations or changes from repulsive to attractive force; but that when the distance is below a certain very small limit it is always attractive up to actual contact, and that beyond this limit resides at least one sphere of repulsion. This repulsive force is that which causes the reflection of light at the external surfaces of dense media; and the interior attraction that which produces the refraction and interior reflection of light.

5. "That these forces have different absolute values or intensities, not only for all different material bodies, but for every different species of the luminous molecules, being of a nature analogous to chemical affinities or electric attractions; and that hence arises the different refrangibilities of the rays of light.

6. "That the motion of a particle of light, under the influence of these forces and its own velocity, is regulated by the same mechanical laws which govern the motions of ordinary matter; and that therefore each particle describes a trajectory, capable of strict calculation as soon as the forces which act on it are assigned.

7. "That the distance between the molecules of material bodies is exceedingly small in comparison with the extent of their spheres of attraction and repulsion on the particles of light.

8. "That the forces which produce the reflection and refraction of light are, nevertheless, absolutely insensible at all measureable or appreciable distances from the molecules which exert them.

9. "That every luminous molecule, during the whole of its progress through space, is continually passing through certain periodically recurring states, called by Newton fits of easy reflection and easy transmission, in virtue of which they are more disposed, when in the former states or phases of their periods, to obey the influence of the repulsive or reflective forces of the molecules of a medium; and when in the latter, of the attractive."

Such are the postulates on which the corpuscular theory of light depends. Most of them may be admitted without difficulty; and they afford data for the application of mathematical reasoning to the phenomena, which may be investigated by the same sort of analysis with which mathematicians are already familiar in the theories of heat, capillary attraction, and other molecular forces.

Undulatory Theory.—The principles of the undulatory theory are thus stated by Sir J. Herschel: —

1. "That an excessively rare, subtle, and elastic medium, or *ether*, fills all space, and pervades all material bodies, occupying the intervals between their molecules; and either by passing freely among them, or by its extreme rarity, offering no resistance to the motion of the earth, the planets, or comets, in their orbits, appreciable by the most delicate astronomical observations; and having inertia, but not gravity.

2. "That the molecules of the ether are susceptible of

being set in motion by the agitation of the particles of ponderable matter; and that when any one is thus set in motion it communicates a similar motion to those adjacent to it, and thus the motion is propagated further and further in all directions, according to the same mechanical laws which regulate the propagation of undulations in other elastic media, as air, water, or solids, according to their respective constitutions.

3. "That in the interior of refracting media the ether exists in a state of less elasticity, compared with its density, than in vacuo (*i. e.* in space empty of all other matter); and that the more refractive the medium, the less, relatively speaking, is the elasticity of the ether in its interior.

4. "That vibrations communicated to the ether in free space are propagated through refractive media by means of the ether in their interior, but with a velocity corresponding to its inferior degree of elasticity.

5. "That when regular vibratory motions of a proper kind are propagated through the ether, and, passing through our eyes, reach and agitate the nerves of our retina, they produce in us the sensation of light, in a manner bearing a more or less close analogy to that in which the vibrations of the air affect our auditory nerves with that of sound.

6. "That as, in the doctrine of sound, the frequency of the aërial pulses, or the number of excursions to and fro from the point of rest made by each molecule of the air, determines the pitch or note; so, in the theory of light, the frequency of the pulses, or number of impulses made on our nerves in a given time by the ethereal molecules next in contact with them, determines the *colour* of the light: and that as the absolute extent of the motion to and fro of the particles of air determines the *loudness* of the sound, so the *amplitude* or extent of the excursions of the ethereal molecules from their points of rest determines the brightness or intensity of the light."

Whichever theory we adopt to explain the phenomena of light, we are led to conclusions which strike the mind with astonishment. According to the corpuscular theory the molecules of light are supposed to be endowed with attractive and repulsive forces, to have poles, to balance themselves about their centres of gravity, and to possess other physical properties which we can only ascribe to ponderable matter. In speaking of these properties it is difficult to divest one's self of the idea of sensible magnitude, or by any strain of the imagination to conceive that particles to which they belong can be so amazingly small as those of light demonstrably are. If a molecule of light weighed a single grain, its momentum (by reason of the enormous velocity with which it moves) would be such that its effect would be equal to that of a cannon-ball of 150 pounds, projected with a velocity of 1000 feet per second. How inconceivably small must they therefore be when millions of molecules, collected by lenses or mirrors, have never been found to produce the slightest effect on the most delicate apparatus contrived expressly for the purpose of rendering their materiality sensible.

If the corpuscular theory astonishes us by the extreme minuteness and prodigious velocity of the luminous molecules, the numerical results deduced from the undulatory theory are not less overwhelming. The extreme smallness of the amplitude of the vibrations, and the almost inconceivable but still measurable rapidity with which they succeed each other, were computed by Dr. Young, and are exhibited by Sir J. Herschel in the following table:—

Colours.	Length of undulation in parts of an inch.	Number of undulations in an inch.	Number of undulations per second.
Extreme Red -	0·0000266	37640	458,000000,000000
Red - -	0·0000256	39180	477,000000,000000
Orange - -	0.0000240	41610	506,000000,000000
Yellow - -	0·0000227	44000	535,000000,000000
Green - -	0·0000211	47460	577,000000,000000
Blue - -	0·0000196	51110	622,000000,000000
Indigo -	0·0000185	54070	658,000000,000000
Violet - -	0·0000174	57490	699,000000,000000
Extreme Violet	0·0000167	59750	727,000000,000000
			The velocity of light being assumed at 192,000 miles per second.

On a cursory view, it must appear singular that two hypotheses, founded on assumptions so essentially different, should concur in affording the means of explaining so great a number of facts with equal precision and almost equal facility. This, however, is the case with respect to the corpuscular and undulatory theories of light, from both of which the mathematical laws to which the phenomena are subject may be deduced, though not in all cases with the same degree of facility. So far as the corpuscular doctrine is available for the purposes of deductive explanation, it possesses all the characteristics of a good theory. It supposes the operation of a force with which we are in some measure familiar. We are accustomed to contemplate the effects of attraction in the grand phenomena of astronomy; we perceive them at every instant in the downward tendency of all heavy bodies; and though they disappear in the small bodies of nature, they are reproduced in the phenomena of electricity, magnetism, capillary attraction, electricity, and various chemical actions, where they can be not only distinctly traced, but reduced to mathematical formulæ, and submitted to accurate calculation. The undulatory hypothesis is not seized by the mind with the same facility; yet it also possesses some of the least equivocal characteristics of philosophical truth. No phenomenon has yet been discovered decidedly at variance with any of its principles. On the contrary, most of the phenomena follow from those principles with remarkable ease; and, in numerous instances, consequences deduced from the theory by a long and intricate analysis, and where no sagacity could possibly have divined the result, have been found to be accurately true when brought to the test of experiment. Hence this hypothesis begins to be generally adopted by philosophers, and, in recent times, by far the most illustrious names in the annals of optical discovery are included in the list of its supporters.

That the sensation of light is produced by the vibrations of an extremely rare and subtle fluid, is an idea that was maintained by Descartes, Hooke, and some others; but it is to Huyghens that the honour solely belongs of having reduced the hypothesis to a definite shape, and rendered it available to the purposes of mechanical explanation. Owing to the great success of Newton in applying the corpuscular theory to his splendid discoveries, the speculations of Huyghens were long neglected; indeed, the theory remained in the same state in which it was left by him till it was taken up by our countryman, the late Dr. Young. By a train of mechanical reasoning, which in point of ingenuity has seldom been equalled, Dr. Young was conducted to some very remarkable numerical relations among some of the apparently most dissimilar phenomena of optics, to the general laws of diffraction, and to the true principles of the coloration of crystallized substances. Malus, so late as 1810, made the important discovery of the polarization of light by reflection, and successfully explained the phenomenon by the hypothesis of an undulatory propagation. The theory subsequently received a great extension from the ingenious labours of Fresnel; and the still more recent researches of Arago, Poisson, Herschel, Airy, and others, have conferred on it so great a degree of probability that it may be almost regarded as ranking in the class of demonstrated truths. "It is a theory," says Herschel, "which, if not founded in nature, is certainly one of the happiest fictions that the genius of man has yet invented to group together natural phenomena, as well as the most fortunate in the support it has received from whole classes of new phenomena, which at their discovery seemed in irreconcileable opposition to it. It is, in fact, in all its applications and details, one succession of *felicities*; insomuch that we may almost be induced to say, if it be not true, it deserves to be so." (*Ency. Metr.*, "Light," § 595.)

Relations of Light and Heat.—Light and heat are so intimately related to each other, that philosophers have doubted whether they are identical principles, or merely coexistent in the luminous rays. They possess numerous properties in common; being reflected, refracted, and polarized according to the same optical laws, and even exhibit the same phenomena of interference. Most substances during combustion give out both light and heat; and all bodies, excepting the gases, when heated to a high temperature become incandescent. Nevertheless, there are many circumstances in which they appear to differ.

A thin plate of transparent glass interposed between the face and a blazing fire intercepts no sensible portion of the light, but most sensibly diminishes the heat. Light and heat are, therefore, not intercepted alike by the same substances. Heat is also combined in different degrees with the different rays of the solar spectrum. A very remarkable discovery on this subject was made by Sir William Herschel, which would seem to establish the independence of the heating and illuminating effects of the solar rays. Having placed thermometers in the several prismatic colours of the solar spectrum, he found the heating power of the rays gradually increased from the violet (where it was least) to the extreme red, and that the maximum temperature existed at some distance beyond the red, out of the visible part of the spectrum. The experiment was soon after repeated with great care by Berard, who confirmed Herschel's conclusions relatively to the augmentation of the calorific power from the violet to the red; but he found the maximum heat existed at the extremity of the red, and not beyond the spectrum. This discovery of the inequality of the heating power of the different rays led to the inquiry whether the chemical action produced by light on certain bodies was merely the effect of the heat accompanying it, or owing to some other cause. By a series of delicate experiments. Berard found that this action is not only independent of the heating power, but follows an entirely different law; its intensity being greatest in the violet ray, where the heating power is the least, and least in the red ray, where the heating

power is greatest. We are thus led to the conclusion that the solar rays possess at least three distinct powers, — those of heating, illuminating, and effecting chemical combinations and decompositions; and these powers are distributed among the differently refrangible rays in such a manner as to show their complete independence of each other.

Light acts a very important part in the vegetable economy. The green colour of plants and the hue of flowers entirely depend on it; and it is found even to influence the form of their leaves. Its effects in developing the forms of some of the lower classes of animals have also been proved by various experiments; and there are probably many other powers resident in the same wonderful agent of which we can at present form no adequate notion. (See *Sir J. Herschel's Treatise on Light; Airy's Mathematical Tracts; Brewster's Optics; Young's Lectures;* Biot, *Traité de Physique;* Pouillet, *Elémens de Physique*.)

Light. In Painting, the medium by which objects are discerned. In a picture it means the part the most illuminated. This may happen from *natural light*, as the sun or moon; or from *artificial light*, as a fire, candle, &c. The principal light is generally made to fall on the spot where the principal figures are placed, and generally near the centre of the picture. A reflected light is that which a body in shadow receives from a contiguous light object.

Light. The sea term for not laden.

LIGHTER. A strong vessel or barge for transporting goods or stores, chiefly on rivers and canals.

LIGHTHOUSE. An establishment for the exhibition of a light or landmark to direct the mariner. The use of lights for such a purpose is of very high antiquity; but their early history is involved in much obscurity. In the ancient world there were lighthouses at Ostea, Ravenna, Puteoli, Caprea, Rhodes, on the Thracian Bosphorus, &c. (*Suetonii Opera*, tom. i. p. 755.); but by far the most celebrated lighthouse in antiquity was that erected by Ptolemy Soter on the small island of Pharos, opposite to Alexandria, —"nocturnis ignibus cursum navium regens." (*Pliny*, lib. v. c. 31.) Its extraordinary height, which some authors have estimated at 500 feet and upwards, procured for it a place among the wonders of the world; and, according to Josephus, its "beaming summit" could be seen at a distance of 300 stadia,—about 42 British miles. It is said to have cost 800 talents; and its celebrity was such that Pharos rapidly became, and still continues to be in many countries, a generic term equivalent to *lighthouse*.

The most celebrated lighthouses of modern times are, the Tour de Carduan, at the entrance of the Gironde, in France; the Eddystone lighthouse, opposite to Plymouth Sound; and that more recently constructed on the Bell Rock, opposite to the Frith of Tay. The first of these was begun in 1584, and finished in 1611. It is 186½ feet (English) in height; and besides being of the highest importance to the sailor on so dangerous and frequented a coast, it forms at the same time a splendid specimen of architectural beauty. The Eddystone lighthouse, constructed by the celebrated engineer Smeaton, was completed in 1759; is regarded as a masterpiece of its kind; and, as has well been observed, bids fair to be little less lasting than the rocks upon which it stands. The Bell Rock lighthouse was built by Mr. Stevenson on the model of the Eddystone. Numerous lighthouses marking the most dangerous points, and the entrance to the principal harbours, are now erected in most civilized maritime countries. In the Baltic and the Sound they are particularly abundant; the Dutch have 20 lights on their coast, and in the Zuyder Zee; and on the northern and western coasts of France there are no fewer than 89 excellent lights. (The Admiralty has lately published lists of all these lights.) But the coasts of no country are so well provided with lighthouses as those of the United Kingdom. For England they are under the management of the Brethren of the Trinity House; for Ireland, under that of the Board for the Improvement of the Port of Dublin; and for Scotland, under that of the Commissioners of Northern Lighthouses meeting at Edinburgh. It would swell our pages to too great an extent were we to attempt to give a complete list of the various lighthouses of this country; we must therefore beg to refer the reader to the *Commercial Dictionary* for full particulars upon this subject, and shall devote what remains of our limits to a view of the different principles adopted in the construction of their important machinery.

The ancient mode of exhibiting lights as beacons to the mariner consisted in burning wood or coal in a chauffer on the top of a tower; and till the year 1807, the Eddystone light was nothing better than the feeble blaze of a few tallow candles, without any apparatus for concentrating the light or giving it any particular direction. But as rays of light proceeding from a luminous focus are equally dispersed over the surface of the sphere which has the focus for its centre, it is evident that without some means of giving the light a horizontal direction, the greater part of it must be wholly lost; for only those rays which are directed in the plane of the horizon, or at least which are depressed only a few degrees below it, can be seen by a ship at a distance. Hence the first object to be attained is to prevent the loss of light by throwing the whole of it forward in the plane of the horizon, in order that its intensity may be increased in the greatest possible degree. Now there are two principles on which this may be accomplished,—reflexion and refraction. The object is accordingly carried into effect by a catoptric or dioptric apparatus. Sometimes both principles are combined in the same apparatus.

Catoptric System.—The usual mode of applying the catoptric principle is by burning an Argand lamp in the focus of a parabolic mirror. This mode of illumination appears to have been first carried into effect at the Carduan lighthouse above mentioned, under the direction of Borda, about the year 1780. A few years later reflecting mirrors were placed in some of the English lighthouses, under the direction of the Trinity House; and in 1786 the principle was adopted in the only two beacons then existing on the coast of Scotland,—viz. the Isle of May in the Firth of Forth, and the Cumbrae Isle in the Clyde. Soon afterwards it was adopted generally in this country. Borda's reflector was formed of a sheet of copper plated with silver; those applied in Scotland were formed of small facets of mirror glass, placed in hollow parabolic moulds of plaster. The mirrors in general use in the British lighthouses at the present time are of copper lined with silver; the focal length is about 3 or 4 inches, and the diameter at the outer edge about 21 inches.

If the curvature of a reflector could be made truly parabolic, and if the light issued from a mathematical point, the rays would be reflected from the mirror exactly parallel to the axis of the generating curve, and the beam of projected light would be a cylinder having a diameter equal to that of the mirror. Such a form of the beam would render the light nearly useless, on account of the small portion of the horizon which would be illuminated; and it is accordingly necessary to give the rays a certain degree of divergence: this is practically effected by the size of the flame. The burner of the lamp is usually an inch in diameter; and the origin of the luminous rays being thus at a small distance from the focus, instead of being reflected parallel they are projected in a cone having a divergence of about 14°. The curvature of the mirror may also be so adjusted as to increase the divergence.

In order to produce a light of sufficient intensity, several parabolic mirrors, sometimes as many as eight, are placed on a frame, with their axes all parallel to each other, so that the light reflected by all of them is blended together in the same beam. To form a revolving light, the frame is attached to a horizontal axis, which is turned by means of clock machinery; and in this manner the different quarters of the horizon are successively illuminated. But as a rapid motion would be inconvenient, the frame has usually three or four sides, on each of which the same number of mirrors and lights is placed; so that the illumination is repeated three or four times in one revolution. To form a stationary light, a number of reflectors are placed round a circular frame, having their axes on the radii of the circle. This arrangement has one obvious defect; namely, that the illumination will not be equally intense at all azimuths, but strongest in the direction of the several axes, and feeblest in the direction of lines bisecting the several angles formed by each pair of contiguous axes. The defect is one which cannot be entirely remedied in a stationary light on the catoptric principle.

Dioptric System.—The introduction of lenses for the purpose of giving the light a horizontal direction is of recent date. A project for this purpose is indeed mentioned by Smeaton in his account of the Eddystone lighthouse, and about the end of the last century the method was tried at some lighthouses in the south of England; but from the imperfect figure of the lenses, and the absorption of the light caused by the great thickness of the glass, it did not succeed. But the art of grinding spherical lenses having been since brought to greater perfection, and a means of greatly diminishing the absorption, and also of constructing lenses of a much greater size, having been found in the use of polyzonal lenses (that is to say lenses formed of several pieces separately prepared and afterwards united,—*see* Polyzonal Lens), the system has been revived of late years, and in many instances carried successfully into execution. The merit of first applying such lenses to lighthouses belongs to the late Auguste Fresnel, of the Academy of Sciences of Paris. The annular lenses, constructed under the direction of Fresnel for the principal lighthouses in France, are plano-convex, having a focal distance of about 3 feet; and they are formed of crown glass, as being less liable to *striæ* than flint glass. The effective divergence of the cone of light projected by a lens is generally less than in

the case of a paraboloidal refractor, being only about 5° 9′. As the luminous cone is formed of only that portion of the light which falls on the surface of the lens, it might be supposed that an apparatus of this kind would be far inferior in its effect to a parabolic mirror; but when it is considered that, owing to the imperfections of the form and polish of the reflecting surface, more than one half of the incident light is lost in every case, and also that a larger and more intense flame may be used for illuminating the lens than can be applied to a parabolic reflector, it will easily appear that the superiority may be on the side of the lens. In fact a lens of the largest size used in the French lighthouses projects a cone of equal intensity to that of eight mirrors of the best kind.

The construction of a revolving dioptric apparatus of the first order is usually as follows:—The revolving frame which carries the principal lenses has eight sides; and there are consequently eight large lenses, so arranged that their axes are all in the same horizontal plane, and meet in the common focus, where the lamp is placed. This frame, with its lenses, consequently forms an octagonal prism. For the purpose of preventing the loss of the rays which fall above and below the principal lenses, various methods are employed. One is to place above the first frame a second frame, whose sides form the frustum of an octagonal pyramid of 50° of inclination, in each of the sides of which is placed a lens having its focus in the flame of the lamp. The rays falling on these inclined lenses are refracted into directions parallel to the axis of the lens, and are then reflected into the horizontal direction by plane mirrors placed above the second frame. Another method is to place curved reflectors above the frame containing the principal lenses. But a third and still more elegant method, proposed by Fresnel, is to substitute for the upper lenses and mirrors a series of triangular prisms, having their axes arranged in horizontal planes, and so adjusted that the light falling on the face next the flame is thrown upon the back of the prism, where it suffers a total reflexion; and a second refraction at the third side of the prism gives it the horizontal direction.

For fixed lights on the dioptric system, it is necessary to increase the number of the lenses, which in fact ought to be infinite, or to form a true cylinder, in order to produce an equal diffusion over every point of the horizon. In some of the French lighthouses the refracting apparatus consists of a polygonal belt of 32 lenses; but on establishing a dioptric apparatus at the Isle of May lighthouse, in 1836, Mr. Alan Stevenson proposed to form a true cylindric belt; and the task, though attended with much difficulty, was successfully executed at a glasshouse in Newcastle.

The dioptric system is peculiarly adapted for fixed lights; and its advantages are these:—1. A light of equal intensity is distributed round every point of the horizon. 2. The consumption of oil is less for the same intensity of light, and consequently the expense of maintaining the light is less. 3. The trouble attending it is less, as there is only one lamp to trim, and the lenses are easily kept in order; whereas the reflecting surfaces require much care and attention. On the other hand, there is more risk from accident, for the accidental extinction of the lamp leaves the whole horizon in darkness; whereas in a system of reflectors the light would be extinguished over only a small portion of it.

Fresnel published his first memoir on the subject in 1822; since that time the dioptric system has been generally adopted for all the principal lighthouses of France and Holland. In this country it has as yet been applied only at Inchkeith and the Isle of May in the Firth of Forth, and at the Star Point in Devonshire.

Lamps.—For the lights on the catoptric system the illumination is usually produced by an Argand fountain lamp, having a burner of an inch in diameter, and tipped with silver, in order that it may the better withstand the effect of the heat evolved. In the dioptric system a larger flame is requisite; and Fresnel invented a lamp, the peculiarity of which consists in its having a series of concentric burners. For lights of the first class the number is four; and they are protected from the effects of the excessive heat by a superabundant supply of oil, which is thrown up from the cistern below by a clockwork movement, and is kept constantly overflowing the wicks. A tall chimney is necessary to supply a sufficiency of air. In this country the lamp is fed with spermaceti oil; in France the oil of colza (expressed from the seed of the wild cabbage) is used; and in some parts of the Mediterranean olive oil, but the light obtained from this is comparatively feeble. In a few instances coal gas has been used for dioptric lights. All attempts to apply the Drummond light, and voltaic lights, have failed, by reason of the great practical difficulties with which those modes of illumination are attended.

Method of distinguishing Sea Lights.—An object of great importance in the establishment of lighthouses is to vary the appearances of the different lights so that each may have some distinctive character by which it may be readily recognized, and the mariner be made aware of the part of the coast he is approaching. Among the methods adopted for this purpose are the following:—1. The interposition of coloured shades before the lenses or refractors, so as to give a particular colour to the light: red is the only colour which can be used, as shades of any other colour are found to absorb too much light. 2. The time of revolution, or the length of the interval between the successive appearances of the light: this is the only mode of distinguishing lights adopted on the French coasts. 3. A *flashing light;* that is, a light of which the alternate flashes and eclipses succeed each other so rapidly as to give the appearance of a succession of brilliant scintillations. 4. An *intermittent light*, which consists of a fixed light which is suddenly eclipsed, and after a stated interval as suddenly revealed: the appearance of this light is entirely different from that of any revolving light. 5. The exhibition of a double light, which admits of other distinctions; for the one light may be placed vertically above the other, or in the same horizontal plane; or one may be white and the other red. Sometimes three lights are necessary to indicate the entrances to harbours, &c.

The average annual expense of maintaining a land light in Great Britain is about 500*l.*, and that of a floating light about 1200*l.*

LI′GHTNESS. (Teut. leicht.) In the Fine Arts, a quality indicating freedom from weight or clumsiness.

LI′GHTNING. An electric phenomenon, produced by the passage of electricity between one cloud and another, or between a cloud and the earth.

The identity of lightning with electricity, though it had been previously suspected, was first directly demonstrated by the celebrated Dr. Franklin, in the year 1749, by the experiment of drawing sparks from the electric kite. Since that time the science of electricity has been greatly advanced; nevertheless, the cause of some of the appearances connected with lightning is not well explained even at the present day.

There are three phenomena in particular for which theory fails satisfactorily to account. The first is the form of the flash, which is almost always zigzag, or in broken lines, making a greater or smaller angle with each other. The second is the frequent repetition of the flashes from the same cloud, which often follow one another in quick succession, contrary to what takes place in the case of electric conductors, which generally recover their natural state or discharge the whole of their electricity at a single stroke. The third is the length of the flash, which sometimes appears to embrace a large extent of the sky. This phenomenon can be best observed from the tops of mountains reaching above the clouds from which the lightning proceeds; and observers in such circumstances agree in stating that they have seen flashes certainly extending several miles in length.

The zigzag form of the flashes is common to lightning and the electric spark: the same explanation should consequently apply to both; but this the theory has not yet been able to give. With regard to the second phenomenon, the repetition of the flashes, we may suppose that the mass of vapours constituting an electric cloud is a less perfect conductor of electricity than metallic substances; and without knowing how electricity is distributed and arranged, so as to be in equilibrium over imperfect conductors, whose surfaces, as in the case of the clouds, often extend many miles, it is easy to see that an instantaneous contact with the ground, or with another substance having an opposite electricity, would not be sufficient to effect a complete discharge; and that, consequently, a single spark would not restore them to their natural state. This we may suppose to be the cause why numerous flashes are darted from the same cloud. With respect to the third phenomenon, the great length of the flash may also be a consequence of the feeble conducting power of the clouds, and of the mobility of their constituent parts; or we may suppose parcels of vapour or air, electrified by the influences of two clouds charged with opposite electricities, to be scattered at very small intervals between the clouds, and that, at a given instant, the equilibrium is destroyed, without a transference of the electricity of the one cloud to the other, but merely from parcel to parcel,

along the whole extent of the line in which the flash appears.

The theory of an electric fluid, and the well-ascertained differences in the conducting power of different substances, suggested the idea of protecting buildings from the destructive effects of lightning by metallic rods. It has been disputed whether conductors ever have been or can be of use in any case; and the question will not probably be satisfactorily answered until the cause and nature of electric action are better understood. *See* ELECTRICITY, THUNDER.

LIGHT-ROOM. A small room from which the light is afforded to the powder magazine of a ship.

LIGHTS, NORTHERN. *See* AURORA BOREALIS.

LI'GNEOUS. (Lat. lignum, *wood.*) In Entomology, a part is so called when it is composed of a hard inelastic substance like wood.

LI'GNIN. (Lat. lignum.) The woody fibre. This most important proximate principle of vegetables exhibits itself in a variety of forms, constituting the different textures of hard and soft wood; and various fibrous products, such as hemp, flax, cotton, &c. When by fine mechanical division it is reduced to a pulpy state, it is formed into paper. When, by different reagents, all the soluble matters are extracted from wood, the insoluble residue is lignin: its ultimate components are charcoal, oxygen, and hydrogen, the latter elements being in the same ratio as in water; so that wood may be considered as a compound of carbon and water, and, according to Dr. Prout's experiments, almost exactly in equal weights. Lignin is very imperishable; but under certain circumstances it is attacked by *dry rot*, arising out of the growth of a parasitic fungus, which causes its rapid decay. Damp timber, in situations where air has not free access, is particularly subject to its attacks; and, when once it has made its appearance, the well-seasoned timber in its neighbourhood becomes liable to the same disease. The dry rot may be prevented by impregnating the timber with certain saline solutions, and of these solution of corrosive sublimate has been found most effectual: the chloride combines chemically with the lignin, and the compound is very indestructible. (*See* DRY ROT.) Lignin has also a strong attraction for alumine; and hence linen, cotton, paper, and other forms of this fibre, may be aluminized by steeping them in hydrated alumine diffused through water; or, more effectively, by soaking them in certain aluminous solutions, drying them, and afterwards washing out the excess of the salt. It is in this way that cotton goods are impregnated with alumine for the purpose of dyeing and calico printing. Other metallic oxides exhibit similar attractive powers, especially the oxide of iron.

The analogy that exists between the composition of sugar, gum, starch, and even vinegar and lignin, suggests the possibility of the conversion of those proximate elements into each other; and it has accordingly been found that, by carefully roasting pure and fine sawdust, it is rendered partially soluble in water, and that a part of it is converted into a nutritious substance, probably intermediate between sugar and starch; and which, when mixed with a little flour, yields a palatable bread, not very unlike that made by some of the inhabitants of the northern parts of Europe of the bark of trees. Mixed with sulphuric acid, lignin passes into gum; and from this sugar may be obtained by boiling it for some hours in a very dilute sulphuric acid: this sugar, when purified, much resembles grape or honey sugar. By this process rags may be converted into nearly their own weight of this peculiar saccharine matter.

The production of vinegar by the destructive distillation of wood was originally suggested, about the middle of the 17th century, by Glauber, a celebrated German chemist of that time: it has lately become a very important branch of manufacture in this country. Upon the whole, there are very few natural products equally important with lignin in their applications to the useful and ornamental arts.

LIGNIPE'RDOUS. (Lat. lignum, and perdo, *I destroy.*) Insects which destroy wood.

LI'GNITE. (Lat. lignum, and ignis, *fire.*) Wood converted into a kind of coal.

LI'GULA. (Lat. *a tie.*) In Botany, a membranous appendage at the apex of the sheathing petiole of grasses, and analogous to the corona of some Silenaceous plants. The term *ligula* is also applied to certain bodies proceeding from the base, and alternate with the horns, of the organ called the *orbiculus* in Asclepiadaceous plants.

LI'GULA. In Entomology, a name applied by Latreille to the lower lip of insects, or *labrum* of English entomologists.

LI'GURITE. A mineral found in a talc rock on the banks of the Stura in the Apennines; it occurs in yellow-green crystals, and, as a gem, resembles the chrysolite.

LILIA'CEÆ. A large natural order of Endogenous plants, with hexapetaloid hexandrous flowers, a superior ovary, and anthers which burst internally. They are familiarly known, in consequence of the asparagus, the lily, the fritillary, the harebell, the star of Bethlehem, and many other common plants, forming a part of the order; which differs from *Melanthaceæ* in having a single style, not three styles, and in the anthers opening towards the style, not towards the petals. The species are extremely varied: some, like the dragon trees, form a tall woody perennial stem, which emulates that of palm trees; others are small bulbous plants, whose stem only lives a few weeks. Almost all the order is sought after by cultivators of beautiful plants; and, in the case of the tulip and the hyacinth, innumerable varieties constitute the riches of the florist. It is the general property of Liliaceous plants to secrete a little stimulating principle; which, in different degrees of concentration and modification, gives their activity to onions, garlic, chives, and similar garden productions, and their medical value to aloes and squills.

LILIA'CEOUS. In Botany, a term invented by Link to denote a corolla, the petals of which have their ungues gradually dilating into a limb, and standing side by side. It is rarely employed.

LI'MA. (Lat. *a file.*) A genus of Lamellibranchiate Bivalves, of the tribe *Ostracea*, characterized by the length of their shells as compared with those of the nearly allied genus *Pecten*, and their more regular oval form. The ridges of the shell are most of them relieved with scales. The *Limæ* swim with rapidity by means of their valves, but in a young state they secure themselves by means of a byssus.

LIMA'CIDÆ. *See* LIMAX.

LI'MACI'NA. (Lat. dim. of limax, *a slug.*) A genus of Testaceous Pteropodous Mollusks, existing in considerable numbers in the northern seas, and forming, with the *Clio borealis* and other small marine animals, the food of the whalebone whale. The body terminates in a spirally convoluted tail, and is lodged in a very thin shell, formed by one whorl and a half, umbilicated on one side, and flattened on the other. The animal uses its light shell as a boat, and its wing-like fins as oars, and thus navigates in countless fleets the surface of the tranquil deep.

LI'MAX. (Lat. limax, *a slug.*) The name of a genus of the Linnæan *Vermes Mollusca*, of which the common slug is the type. The genus enters into the class *Gasteropoda* and order *Pulmonaria* of the system of Cuvier; and is now raised to the rank of a family (*Limacidæ*), which includes *Limax* proper; *Arion*, Fér.; *Stenopus*, Guild.; *Vaginulus*, Fér.; *Testacella*, Lam.; *Parmacella*, Cuv., &c. Each of these genera has a small scutiform rudimental shell developed in the substance of the mantle, and protecting the heart. The orifice of respiration in the true slugs (*Limax*, Cuv.) is on the right side, and not so far forward as in *Arion*. The rudimental shell is marked with fine and concentric striæ, and is calcified internally. The species of this genus are the pests of gardens and cultivated grounds. Young plants may be protected from slugs by having a coarse horsehair rope coiled round their stems, or by being plentifully sprinkled with soot; or they may be watered morning and evening with strong and fresh lime water.

LIMB, in Astronomy, signifies the border or outermost edge of the sun or moon. Also the graduated edge of a circle, or other astronomical instrument.

LI'MBERS. In Artillery, a sort of advanced train to which the carriage of a cannon is attached on a march. It is composed of two shafts, wide enough apart to receive a horse between them, joined by two bars of wood, and mounted on a pair of wheels.

LI'MBO. (Lat. limbus, *a hem or edge.*) A region supposed by some of the school theologians to lie on the edge or neighbourhood of hell. This served as a receptacle for the souls of just men, not admitted into purgatory or heaven. Such were, according to some Christian writers, the patriarchs and other pious ancients who died before the birth of Christ: hence the limbo was called Limbus Patrum. These, it was believed, would be liberated at Christ's second coming, and admitted to the privileges of the blessed in heaven. Though some have asserted that, when our Saviour went down into hell, he liberated these souls, and carried them away with him into heaven. This latter idea is probably an adorned representation of the remarkable passage in St. Peter's Epistle (i. 3. 19.), where he says that Christ preached to the spirits in prison; and, being held by certain of the later fathers, seems to have given some influence to the growing opinion in favour of a purgatory. The limbus puerorum, or infantum, was a similar receptacle allotted by some of the schoolmen to the souls of infants who die unbaptized. Dante has fixed his limbo, in which the distinguished spirits of antiquity are confined, as the outermost of the circle of his hell. The use which Milton has made of the same superstitious belief is well known. (*Paradise Lost*, book iii.)

LI'MBUS. A term applied to petals, to denote that portion which is supported by the unguis; it is the same organ in a petal as the lamina in a leaf, and is what constitutes the broad, thin, coloured part which renders many flowers so beautiful.

LIME. (Germ. leim, *glue.*) This very useful earth is

obtained by exposing chalk and other kinds of limestone, or carbonates of lime, to a red heat,—an operation generally conducted in kilns constructed for the purpose; the carbonic acid is thus expelled, and lime, more or less pure, according to the original quality of the limestone, remains. In this state it is usually called *quicklime*. When sprinkled with water it becomes very hot, and crumbles down into a dry powder, called *slaked lime*, or *hydrate of lime*. When exposed for some weeks to the air it also falls into powder, in consequence of the absorption of moisture, and of a portion of carbonic acid; so that, in this case, part of the lime gradually reverts to the state of carbonate, and loses its causticity. Pure lime may be obtained by heating powdered Carrara marble to whiteness in an open crucible. It is white, very infusible, highly luminous when heated to full redness, and of a specific gravity of about 2·3. It requires for solution about 500 parts of water, and is somewhat more soluble in cold than in hot water. But, weak as this solution is, it acts powerfully alkaline upon vegetable colours, and has an acrid taste; hence the term *alkaline earth* applied to lime. It absorbs carbonic acid by exposure to air, and as *carbonate of lime* is insoluble in water, it becomes milky in consequence; so that, from this property, lime-water is a useful test of the presence of carbonic acid. The nature of lime was first demonstrated by Davy in 1807: he showed that, like the other alkalies, it was a metallic oxide. The metallic base of lime has been termed *calcium:* its equivalent is 20, and lime, being a compound of one atom of calcium and one of oxygen, is represented by the equivalent number 28; and hydrate of lime by 28 lime + 9 water = 37. The *salts of lime* are generally obtained by dissolving carbonate of lime in the respective acids: several of them exist native. *Sulphate of lime*, selenite, or gypsum, is an abundant natural product, and may be formed artificially by adding sulphuric acid, or the soluble sulphates, to solutions of the salts of lime. It consists of 28 lime + 40 sulphuric acid, and its crystals include two atoms = 18 of water. When these crystallized sulphates of lime are heated they part with their water and fall into a white powder, called *plaster of Paris;* when this is mixed with water it again combines with it, and concretes into a white mass; hence its use for casts, busts, &c. Sulphate of lime is often contained in spring water, which is thus rendered *hard* and unfit for washing. These waters become turbid upon the addition of a spirituous solution of soap. *Phosphate of lime* is found *native*, constituting the mineral called *apatite:* this is a *subphosphate*, composed of 3 equivalents of lime = 84, and 2 of phosphoric acid = 72. The *earth of bones* is also chiefly a similar phosphate of lime. *Oxalate of lime* is very insoluble, and is precipitated whenever oxalic acid or a solution of an oxalate is added to solutions containing lime; hence it is that oxalate of ammonia is so valuable a test of the presence of lime, and is frequently used for the purpose of separating lime in analysis. When oxalate of lime is well dried, at 500°, it is anhydrous, and consists of 28 lime + 36 oxalic acid = 64 oxalate of lime. This substance is occasionally found in the human urine, and sometimes forms calculi: these are often of a reddish brown colour and a rough exterior, whence they have been termed *mulberry calculi*. When hydrate of lime is exposed to chlorine, the gas is absorbed, and a *chloride of lime* is obtained. This article is manufactured upon an extensive scale, under the name of *bleaching powder*. It evolves chlorine when acted upon by acids; and gives it out very slowly when exposed to air, in consequence, probably, of the absorption of carbonic acid. It is a most useful disinfecting material, and, when dissolved in water, forms *bleaching liquid*. *Carbonate of lime* is thrown down when alkaline carbonates are added to solutions of the salts of lime. It is a most abundant natural product, and is found pure in the varieties of calcareous spar and statuary marble. Chalk and several varieties of limestone are also nearly pure carbonates of lime. It is easily distinguished from other minerals by effervescing in dilute muriatic acid, and by yielding quicklime when a fragment is heated before the blowpipe. It is constituted of 28 lime + 22 carbonic acid: the equivalent, therefore, of carbonate of lime is 50.

The uses of lime are very numerous. Its most important application is in the manufacture of mortar and other cements used in building. It is also very extensively used in this country, and in some parts of the Continent and North America, as a manure to fertilize land. But it is a curious fact that the use of lime as a manure is entirely a European practice, its employment in this way having been never so much as dreamed of by the natives of Asia or Africa. (See *Commercial Dict.*)

LI'MESTONE. A generic term for those varieties of carbonate of lime which are neither crystallized nor earthy; the former being *calcareous spar*, the latter *chalk*. When burned they yield quicklime. *See* GEOLOGY.

LI'MIT, in Geometry, denotes a given or determinate quantity to which some other variable quantity continually approaches in value, but which it can never exceed. Thus, if we suppose a polygon to be inscribed in a circle, by increasing the number of sides of the polygon its area is increased. But the area can never exceed that of the circle within which the polygon is inscribed; and it is only when the number of its sides is conceived to be infinitely great that its area becomes equal to that of the circle. The circle is thus said to be the limit of the areas of the inscribed polygon.

Method of Limits, the same with the *method of prime and ultimate ratios;* a peculiar method of analysis employed by Newton in the *Principia*, equivalent to fluxions or the differential calculus, but preserving the form of the ancient geometry.

LIMITA'TION OF ACTIONS AT LAW. The period beyond which personal actions of trespass, or debt on simple contract, cannot be brought is defined by the stat. 21 J. 1. c. 16. They must be commenced within six years after the cause of action; with the exception of actions of assault, menace, and imprisonment, which are limited to four. But a right of action may be revived by an express acknowledgment on the part of the debtor.

Penal actions for forfeitures made by statute must be sued in general, according to the terms of the statutes, within two years or one year.

By the recent statute 3 & 4 W. 4. c. 27., all process for the recovery of land by entry and distress, or by action, whether real or mixed, must be commenced within twenty years after the right of action accrued. Persons under the disabilities of infancy, coverture, idiotcy, lunacy, unsoundness of mind, or absence beyond seas, are allowed ten years after the termination of their disability; so that forty years be in all cases the extreme limit. This statute extends both to suits in equity and actions at law. No advowson can be recovered after one hundred years. Money charged upon land, and legacies, are deemed satisfied at the end of twenty years, unless there have been some receipt or acknowledgment. Arrears of rent, or interest of money charged on land, cannot be recovered after six years. But it has been thought that this limitation has been extended by the subsequent statute 3 & 4 W. 4. c. 42., which enacts that actions of covenant and debt for rent, &c. may be brought at any time within 20 years after the cause of action has accrued.

The statutes of limitations apply to equitable remedies directly, and by the plain import of the statutes, where the equitable remedy is sought (as it may be in some cases) for a right enforceable at law; and they have been adopted by analogy in those cases where a purely equitable right is the counterpart of a legal one, as the right to mesne profits in respect of an equitable ownership, or a debt payable in equity but not in law. Where there is not this strict correspondence between the equitable and legal claims, the rule prevails that twenty years' adverse possession, which is in law a bar to the possessory action for land, shall be a bar to all equitable claim, whether the adverse right be merely equitable also or equitable and legal; such period of limitation being, as at law, capable of extension from infancy, absence, or disability. But time is not a bar to the claim of cestui que trust against his trustee, where the trusteeship was in the origin direct and express, and not coupled with any beneficial interest, as it is in the case of a mortgage; nor does a purchaser, with notice from a trustee, stand in a better situation in respect to time than the trustee himself.

LI'MNEUS. (Gr. λιμνη, *a pool.*) A genus of freshwater snails; so named from their general location in ponds, ditches, and other receptacles of stagnant water. Many species of this genus are natives of Britain.

LI'MNING. The art of painting in water colours; in which sense it is used to distinguish it from painting in oil colours.

LIMO'SA. (Lat. limus, *mud.*) A genus of wading birds, belonging to the *Longirostrus* tribe; and characterized by a straight beak, longer than that of the snipes (*Scolopax*), and sometimes slightly bent at the extremity; the nasal groove extends close to the tip, which is blunt and somewhat depressed; there is no third groove or punctation on its surface. The external toes are palmated at the base: they are longer and slenderer than in the snipes. The species of *Limosa* which, with us, are vernacularly termed Godwits, frequent salt marshes and the sea shore.

LI'MULUS. (Lat. limus.) A genus of gigantic Entomostracous Crustacea, in which the haunches of the first six pairs of feet are beset with small spines, and are so closely approximated about the mouth as to serve the office of jaws. The œsophagus, instead of proceeding backwards, is continued forwards for a short distance into the anterior part of the shield before it enters the stomach: this cavity is lined with a thick rugous cuticle, and terminates in the intestine by a long muscular and valvular projection. The heart is elongated, vasiform, and muscular; the branchiæ are supported on a series of closely-packed broad plates beneath the postabdomen. The total number of feet is twenty-two: the first ten, with the exception of the two anterior ones in the males of some species, are terminated by a didactyle forceps, and are inserted, with the two following pairs,

beneath a large semilunar shield. The species of this genus are found on the shores of the North American and Asiatic continents: they are commonly known by the names of king crabs, horse-shoe or mollusca crabs. The tail is long, straight, sharp-pointed, and of sufficient strength and size to be used as a spear-head or arrow-point by savages.

LINA'CEÆ. (Linum, one of the genera.) A small natural order of herbaceous Exogens, principally inhabiting Europe and the North of Africa; allied, according to De Candolle, to *Silenaceæ*, *Malvaceæ*, and *Geraniaceæ*. Aug. de St. Hilaire considers them to be a mere section of *Geraniaceæ*. The want of a gynobasic structure, the imbricate calyx, the regular flowers, and the small quantity of albumen in the seeds, rather point out an affinity with *Cistaceæ* and its allies. Their chief characters are the tenacity of their fibre, the mucilage of their seeds, and the beauty of their flowers. Common flax or lin (whence linseed) is the most important plant of the order.

LINE, in Military Affairs, is a term used to distinguish what may be called the regular infantry of Great Britain from other military corps or establishments. Thus all numbered infantry or marching regiments, with the exception of the Foot Guards, are designated by this term, in opposition to the cavalry, the artillery, the engineers, the marines, the militia, the yeomanry, &c.

LINE, in Fortification, signifies any extended defence; as a ditch with its parapet, a row of gabions, &c.

LINE, in Geography and Navigation, is used for the equator; as equinoctial *line*.

LINE. In Geometry, a magnitude having only one dimension. Euclid defines it to be "that which has length without breadth."

LI'NEAR. In Geometry, a linear problem is one that is solved by the intersection of two straight lines, or by an equation of the first degree, and which, consequently, admits only of a single solution.

Linear Equations, in the Integral Calculus, are those in which the unknown quantity is only of the first degree. Thus $Ax + B = O$ is a linear equation, if A and B are not functions of x; and $A\,dy + By + C = O$ is also a linear equation, when A, B, and C do not contain y.

Linear Perspective is that which regards only the positions, magnitudes, and forms of the objects delineated; as distinguished from *aërial perspective*, in which the variations of the light, colour, and shade of objects, according to their different distances and the quantity of light that falls on them, are also considered and represented.

LINEN. (Germ. leinwand.) A species of cloth woven with the fibres of the flax plant (*Linum usitatissimum*). The origin of the manufacture of linen is lost in its antiquity. In the time of Herodotus linen was an article of export from Egypt, where it had been used from time immemorial; but it is evident that in ancient times its use was limited to the noble and the rich. In modern times linen constitutes a staple manufacture in almost all European countries; but more especially in Germany, Russia, Switzerland, Flanders, England, Scotland, and Ireland. In England it has been prosecuted for a very long period; but until of late years its progress has been inconsiderable, compared at least with that made in other branches of manufacture. This seems to be partly owing to the attempts to bolster up and encourage the manufacture in Ireland, partly to the absurd restrictions that were for a lengthened period laid on the importation of foreign flax and hemp, and partly to the rapid growth of the cotton manufacture — fabrics of cotton having to a considerable extent superseded those of linen. It is only within the last fifty years that any machinery has been used in the production of linen cloth, the first mills for the spinning of flax having been constructed at Darlington about forty-eight years ago. (*See* FLAX, HEMP.) The principal seat of the manufacture is—in England, Leeds and its immediate vicinity, and in Lancashire, Dorset, Durham, and Salop; in Scotland, Dundee, which indeed may be regarded as the chief seat of the British manufacture (see *Geo. Dict.*, art. "Dundee"); and in Ireland, the province of Ulster. The entire value of the linen manufacture of Great Britain and Ireland is estimated at 8,000,000*l.*, and the total number of persons employed in it about 185,000. (*Statist. of the Brit. Empire*, vol. i. 679.)

LINE OF BATTLE, is the line formed by the ships of the fleet when ranged ahead and astern of each other, at equal distances, and close-hauled, or nearly so. It may be formed accordingly upon either tack. The line is composed of ships of not less than two decks, thence called *line-of-battle-ships*. The line is also called the *line ahead*.

LINE OF BEARING, THE, is formed by the ships of the fleet when ranged on a line six points from the wind, at equal distances, and with their heads in any direction whatever. The line is called by the name of that tack upon which if the ships were to haul to the wind together they would form the line ahead. For example: suppose the wind N., and the ships in a line W. N. W. and E. S. E. of each other; this is the *starboard* line of bearing, whether the ships are going free, or close-hauled upon the *larboard tack*.

LINE OF DIP. In Geology, the strata which form the crust of the globe are rarely horizontal, but incline to some point of the horizon, and rise to the opposite point; a line drawn through these points is called the line of their *dip*.

LI'NGUA. (Lat. *a tongue*.) In Entomology, the name of an organ situated within the labium or emerging from it, by which insects, in many cases, collect their food and pass it down the pharynx, which is situated above its root.

LI'NGUA FRA'NCA. The dialect spoken chiefly along the European and African coast of the Mediterranean. It is a species of corrupt Italian, mingled with words of other languages, and may be termed the Creole of the Mediterranean.

LI'NGULA. (Lat.) A genus of Palliobranchiate Bivalves, with two nearly flat, smooth, oblong, triangular valves, attached between the two apices to a long fleshy pedicle. The arms, or labial appendages, are spirally convoluted, as in the rest of the class.

LI'NIMENT. (Lat. lino, *I anoint*.) A semifluid ointment, or a soapy application, to rub upon painful joints. The term is also applied to spirituous and other stimulating applications for external use.

LI'NING. In Architecture, any covering of an interior surface. The linings, for instance, or boxings of window shutters, are the pieces forming the backs of the recesses into which the shutters are folded. In doorways, they are the facings on each side the aperture: to sashes, they are the vertical pieces parallel with the surface of the walls.

LI'NTEL. (Span. lintel.) In Architecture, an horizontal piece of timber or stone, over a door, window, or other opening, to discharge the superincumbent weight.

LION. (*Felis leo*, Linn.) The largest, most formidable, and most noble of the Carnivorous animals, though not the most typical of the genus at which it stands at the head. It is chiefly distinguished by the presence of a full flowing mane in the male, and by a tufted tail and the disappearance of the feline markings in both sexes before they arrive at maturity; the colour then being a nearly uniform light fulvous brown, with mane inclining to black, especially in the Central and South African races. The mane is scantier and lighter coloured in the Asiatic than in the African lions; and there exists a maneless variety in the eastern parts of Hindostan. *See* FELIS.

LION. In Heraldry, a beast, of which the figure is very commonly borne as a charge. The attitudes in which the lion is represented are very various. (*See* RAMPANT, PASSANT, REGARDANT, GARDANT, COUCHANT, SALIENT, SEJANT.) A lion passant is termed, in French heraldic language, a leopard; and hence the common notion that the lions of England were substituted for leopards.

LION OF ENGLAND. A lion passant regardant or (being the bearing of England), is frequently thus termed in heraldry.

LIP. A term applied to either of the two divisions of a Monopetalous corolla, where one portion takes a direction upwards and the remainder a direction downwards, as in *Labialæ*. It is the same as *labellum*, which see.

LI'PARIS. (Gr. λιπἀρος, *glistening*.) The name of a genus of Lepidopterous insects; also applied by Pliny to a genus of fishes. In Botany, it is the name of a genus of plants of the Orchidaceous order.

LIPOGRAMMA'TIC WORKS or WRITINGS. (Gr. λειπω, *I omit*, and γραμμα, *a letter*.) Compositions in which a particular letter is omitted throughout. The ancients produced many ingenious trifles of this description. In the *Odyssey* of Tryphiodorus there was no A in the first book, no B n the second, and so on. There are other pieces of modern invention, such as the *Pugna Porcorum*, in which all the words begin with the letter P. Odes in Spanish, containing only one of the vowels, are refinements on the same invention.

LIPO'RNA. (Gr. λιπος, *fat*.) A soft fatty tumour.

LIPPITU'DO. (Lat. lippus, *blear-eyed*.) The disease commonly called *bleared eyes*, consisting in a puriform exudation from the margin of the eyelids, which often causes them to adhere together after sleep.

LIQUEFA'CTION. (Lat. liquefactio.) The act of melting or of fusion. This term is also used synonymously with *solution*.

LI'QUIDS. In Grammar, the letters *l*, *m*, *n*, and *r* are so called.

LI'QUOR SI'LICUM. Liquor of flints. A solution of silicated potash.

LIRE'LLA. In Botany, a term used in describing lichens to denote a linear shield, with a channel along its middle, as found in *Opegrapha*.

LIST. The enclosed field or ground wherein the ancient knights held their jousts and tournaments; so called from its being encircled with pales, barriers, or

stakes, as with a list. Some of these were double, one for each cavalier, which kept them apart, and prevented them from coming nearer each other than a spear's length. Hence the expression *to enter the lists* is synonymous with engaging in contest.

LIST. The name given to the border or selvage of a piece of cloth, &c.

LIST, or LISTEL. In Architecture, the same as fillet or annulet.

LIST, CIVIL. *See* CIVIL LIST.

LI'STING. (Fr. leziere.) In Architecture, the cutting away the sappy part from the edge of a board.

LI'TANY (Gr. λιτανια, *supplication*), signifies a general supplication; and was applied by the Eastern church in early ages to a special form of prayer which was introduced into the ritual, or used on particular occasions. The term passed over into the Western church, where the words *rogatio* and *supplicatio* had before been used in the same technical sense. It is supposed by Palmer (*Antiq.* i. 269.) that the change of term was occasioned by the frequency of processional supplications from the Eastern to the Western churches, beginning in the 4th century. It appears that some of the Eastern litanies contain the supplication to saints which forms a distinguishing feature of the Roman. This is sufficient to justify the English church, even on antiquarian grounds, in rejecting these portions of the service. Our litany is mostly translated from the forms of the Western litanies previously used in this country; those of the breviary of Salisbury and York. The direction in the Prayer Book is that the litany shall be read on Wednesdays, Fridays, and Sundays: on the two former, as fastdays in the primitive church; the one as the day in which Christ was sold by Judas, the other as that of the crucifixion, and therefore periods of peculiar humiliation: on the Sunday, as the day appointed for the most complete and solemn service in the week. (See *Riddle's Christian Antiquities*, p. 623., 1839; *Palmer's Origines Liturgicæ*, i. 264.)

LITERA'TI (Lat.), denotes, in general, learned men; but is applied in China to such persons as are able to read and write their own language, and also to a particular sect, consisting chiefly of the most learned men of that country; amongst whom it is called *Jukiao*, or learned. It is from the class of the literati that the mandarins (*quod vide*) are alone capable of being selected.

LI'TERATURE (Lat. litera, *letter*), comprises, in the general sense of the word, the entire results of knowledge and fancy preserved in writing; but, in the narrower use to which ordinary custom restricts it, we draw a distinction between literature and positive science, thus exempting from the province of the former one extensive branch of our studies and attainments. And, in a still more restricted sense, the word literature is sometimes used as synonymous with *polite* literature, or the French *belles lettres* (which see).

The history of literature is a peculiar and distinct subject, comprising several subdivisions, such as histories of the literature of special ages or countries; or histories of separate branches of literature, such as poetry. For its complete execution it requires an union of bibliographical knowledge with critical acumen. It should give the reader a sufficient acquaintance with the titles, contents, and dates of remarkable books, and with the general biography of remarkable authors, together with a critical appreciation of the characters and value both of authors and books, and of the dependence, connection, and derivation of literature; that is, the mode in which opinions, taste, and style have been propagated or changed. This last, as it is the most difficult part of the subject, so is it that of which the execution has been hitherto most imperfect.

Antiquity has left us no relics of this species of history; although the constant references of such writers as Cicero, Pliny, and Quintilian, to earlier authors, accompanied by critical appreciation of their merits, show that the taste and materials for it were not wanting. A remarkable passage of Velleius Paterculus, in which he shows, by historical instances, how many of the great names of antiquity were cotemporary with each other, in limited periods of time, clustering, as it were, together in particular seasons and places, is one of the earliest instances we have of that spirit of generalization from literary phenomena which is now so common as to leave little room even for the display of originality.

In the following brief notices of the principal works of general literary history which the student has it now in his power to consult, we shall follow, in great measure, the criticisms of Mr. Hallam, in the Preface to his *Introduction to the Literature of Europe in the Fifteenth, Sixteenth, and Seventeenth Centuries*. The oldest work of this description (if such it can be called) is that of Polydore Virgil, *De Inventoribus Rerum*, 1499. Conrad Gesner, who has been termed the "father of literary history," published his *Bibliotheca Universalis* at Zurich, 1545-55. Notwithstanding these and a few other meagre attempts, Lord Bacon, says Mr. Hallam, was justified in denying that, up to his time, any real history of letters had been written: "and he compares that of the world wanting this to a statue of Polyphemus wanting his single eye." The next in order of time is *Lambuc's Prodromus Historiæ Literariæ*, 1659; a work pursued on a great plan, but scarcely begun. But *Morhof's Polyhistor Literarius*, first published in 1688, and much enlarged by subsequent editors, "is still found in every considerable library." Andrès, a Spanish Jesuit, published his *Origine, Progresso, e Stato Attuale d'ogni Letteratura*, from 1782 to 1799; a very extensive, and, in some respects, valuable work, though without much display of taste, and no signs of genius. In the present century, no writers, except of Germany, have attempted a field which has become of such enormous extent; but *Eichhorn's Literary History*, in six volumes, 1805, 1811, appears to be now, on the whole, the most complete and valuable work of this kind extant. *Waehler's Manual of Literary History*, in four volumes, appeared at Leipsig in 1833.

But besides these general compendia, much assistance is to be derived from general biographers. Of these the well-known Dictionary of Bayle, first published in 1697, is the earliest of any value. It is characterized by Hallam (p. xi.) in a manner perhaps too depreciating. That of Niceron, *Mémoires pour servir a l'Histoire des Hommes illustres de la République des Lettres*, 43 vols. 12mo. 1733, 1745, is extraordinarily copious, and useful in biographical details, but in other respects of no great value. The *Biographie Universelle* (of which the original edition was in 52 volumes, and a supplement is now in course of publication which has reached the letter H) stands incomparably first among this class of works. *Chalmers's Biographical Dictionary* scarcely deserves mention as a literary work; but its historical details are sometimes minute and useful, though not unfrequently most so in the obscurest names.

Of *partial* works on literary history some of the most remarkable and useful are, 1. According to subjects — History of Philosophy, Brucker, Buhle, Tennemann (abridged by Victor Cousin). To these we may add, brief as they are, the Introductory Essays of Stewart and Playfair to the *Encyclopedia Britannica*. Of Belles Lettres, generally, Bouterwek, 12 vols. 8vo. Poetry, Quadrio, *Storia d'ogni Poesia*; a work of remarkable industry, though strangely defective in point of critical taste. 2. According to countries — French: Laharpe, *Cours de Litterature Française*; a performance of considerable, but in parts superficial and showy, talent. Italian: *Tiraboschi, Storia della Letteratura Italiana;* a work of extraordinary value, in which the history of Italian literature has been traced, with the greatest care and the most elaborate research, from the earliest times down to the last century. It has been abridged, but with some original criticism, by Ginguené, in his *Histoire Litteraire de l'Italie;* Corniani, *Secoli delle Letteratura Italiana dopo il suo risorgimento*, 1804, 1813. *Sismondi's Litterature de Midi de l'Europe* is most valuable, also, in its Italian chapters, although those on Spanish and Portuguese literature touch on subjects less generally known. In England, as Mr. Hallam observes, "we cannot claim for ourselves a single attempt of the most superficial kind. *Warton's History of Poetry* contains much that bears on our general learning; but it leaves us about the accession of Elizabeth." 3. According to ages: — The recent work of Mr. Hallam, which comprehends the literary history of Europe from 1400 to 1700; a work almost approaching to universal in its character. Its peculiar excellences are a philosophical spirit, manliness and candour of judgment, great honesty in the execution, and a taste unusually cultivated and correct. It is, however, as might be expected from a work of so comprehensive a character, unequal both in the space which it allots to different subjects and authors, and in point of execution.

The love of literature is, perhaps, the most remarkable and characteristic form in which advancing civilization exhibits itself. From being the absorbing passion of the learned few, it becomes, with the progress of education, the delight and favourite occupation of numbers; losing, perhaps, in intensity what it gains in universality. For, without joining in the views of the indiscriminate eulogisers of past times, it cannot, we think, be fairly denied that the engrossing devotion to study which characterized the learned men of the first two centuries after the revival of knowledge, especially in the branches of philology and divinity, rarely finds a counterpart at the present day. More diversified subjects of interest now present themselves to the inquiring mind: objects in themselves of inferior character, such, for example, as the establishment of correct rules of classical composition, are less appreciated, because we have daily opportunities of discussing topics of much higher interest, from which it is difficult to carry back the faculties to pursuits of special investigation. That all this has some disadvantages it were vain to deny. Some imagine that not only extent and minuteness of knowledge, but real depth of learning and

power of mind, are more rare among the literati of the present day than heretofore; that we have lost in profundity, to use the common expression, what we have gained in surface. Of that opinion we are not. But we imagine ourselves to trace, both in the composition and tone of thinking of the day, a want of finish and harmony of tone — a want of those qualities which are the result of patience, and of that complacent dwelling of the mind on some favourite object of study which was so common in former ages. The powers of men of ability are too much dissipated, both by the vast variety of subjects pressing on their attention, and by the temptation to satisfy the cravings of the public by hasty execution.

On the other hand, in the four literary countries of the present day — France, Germany, England, Italy, and especially the three former — the number of persons to whom literature furnishes the sole and beloved *recreation* has increased, within the last century, we may add the last generation, to an amount perfectly surprising. Were it possible to calculate the number of individuals more than half of whose waking hours are spent in reading, and writing on literary subjects, the result would be startling. In Germany the number of books published has nearly trebled since the peace of 1815. The great bulk of the increase belongs to literature specially so called. In France and England the accumulation is scarcely less. And by the process, common in all these countries, of circulating libraries, the same copy of a book performs an infinitely greater quantity of service, passing under the eyes of many more readers than heretofore. It is curious, among ourselves, to trace the decline of the favourite amusements of our ancestors. The theatres are almost deserted by the ranks which used to frequent them. The public assembly rooms of the rich, the suburban places of resort for nightly entertainments, once so common among the middle classes, are alike falling into comparative disuse. Of the increased infrequency of play, or even games of skill, in society, every one can judge. Of wine the consumption has certainly not increased one half in a century, while the number of consumers has probably been quintupled or sextupled. All these things afforded a certain quantity of *occupation;* and the substitute for one and all has been the same — literature.

It is plain, therefore, how far more important a part than heretofore literature must perform in modelling the public mind of nations. There have been times when it scarcely represented the national disposition at all; but merely that of a class by which it was encouraged. Any one who were to judge of the social state of England under Charles II. by its literature, would pronounce that the nation comprised a learned class of great knowledge, but visionary and unpractical habits of mind; and a frivolous, coarse, debauched community. Yet, in truth, the great bulk of the nation was staid, sober, religious, and of a plain and business-like character. The literature of the latter part of Louis XIV.'s reign is grave, decorous, even rigorous in tone; because such was the affectation of the court. The people are not represented in it at all. Such anomalies are now impossible. The floating literature of the day is and must be the real expression of the popular mind.

Now the effect of literature on the moral habits of man is incalculable. It is the remark of a profound religious writer of the present day, that we frequently read a literary work without acquiring any positive knowledge at all, or forgetting it as soon as acquired; but very rarely without receiving some moral impression. And in this view we regard the predominance of literary habits in a nation as advantageous. For, unless public taste is very far corrupted indeed, the tone of morality in the ordinary literature of the day, to meet approval, must be good: not solidly good perhaps — superficial, it may be, and occasionally false; but still more right than wrong. And such a tone of literature, reacting on the minds of the public, will tend to preserve and augment right feelings in the reading classes. The more special tendencies of literary habits seem to be to soften the disposition, — to melt down rancorous feelings, — to encourage benevolence of sentiment, and a ready sympathy with generous conduct. That they serve essentially to promote self-denial and self-devotion, and virtue of the higher order, we do not contend; but we see no ground for the suspicion which some entertain that they are incompatible with the sterner stuff of these more serious qualities, or tend to weaken the main springs of thought and action. On the other hand, although a prevalence of literary habits may render the success of an utterly corrupt style of literature more improbable; yet, when such success does occur, its effects must be infinitely more noxious and destructive. Were such a taste as French lighter literature has of late exhibited likely to obtain a real ascendency in that country, there could not be a more powerful cause, as well as decisive symptom, of national degeneracy; but, in truth, it will prove only a temporary extravagance.

One more effect of the spread of literary habits remains to be noticed — the enormously increased importance of what may now be justly termed the literary profession. Such fortunes as that of Sir Walter Scott are phenomena belonging to this age alone. At this moment (November, 1840) the two contending party leaders in France, on whom the eyes of Europe are fixed, are writers by profession, who have risen to their present eminence through literary distinction; and of the most noted public men on both sides, several belong to the same class. Spain has had a play-writer for her prime minister. In Germany, when a national movement is attempted against an alleged act of usurpation on the part of a sovereign, those who assume the lead are the professors of an university. In England, the less excitable nature of the people, and the great influence of wealth and aristocratic distinction, have kept the great men of the press hitherto in a state of comparative subordination. But a little attention to the signs of the times will lead us to suspect that, if the frame of our society were shaken by any sudden impulse, men of this class would assume a more marked position than they have hitherto occupied. This is the brilliant side of the picture. On the other hand, the multiplication of a body of men whose employment is essentially precarious, their remuneration irregular, their education high, their tastes luxurious, their wants numerous, their success requiring a constant strain upon the spirits and activity of the brain, is in some respects a thing to be regretted. In ill-governed and restless communities they form the most dangerous class; in orderly and flourishing ones they contribute greatly to the brilliancy of society, but at the expense of much of their own peace and happiness. We have outlived the days when the ideas of poverty and learning were habitually associated, and the custom of the humiliating dependence of intellect on wealth, —

Toil, envy, want, the *patron* and the gaol;

but the young aspirant to literary distinction may be usefully reminded of the words of a great writer of our day. "Never" (that is, with a free choice before you) "pursue literature as a profession. It would be a sort of irreligion, and scarcely less than a libel on human nature, to believe that there is any established and respectable profession or employment in which a man may not contrive to act with honesty and honour; and doubtless there is likewise none which may not at times present temptations to the contrary. But wofully will that man find himself mistaken who imagines that the profession of literature or, to speak more plainly, the trade of authorship, besets its members with fewer or with less insidious temptations than the church, the law, or the different branches of commerce. Let literature be an honourable augmentation to your arms, but never fill the escutcheon." (*Coleridge, Autobiographia Literaria.*)

LITHA'RGE, *Lythargyrum*. (Gr. λιθος, *a stone*, and αργυρος, *silver;* probably from its silvery appearance.) Fused oxide of lead. *See* LEAD.

LI'THIA. (Gr. λιθειος, *lapideous.*) A rare alkaline substance, discovered in 1818 by M. Arfwedson in a mineral called *petalite;* it has also been found in some other lapideous bodies. It is distinguished from potassa and soda by the difficult solubility of its carbonate; from baryta, strontia, and lime, by the solubility of its sulphate and oxalate; and from magnesia by the alkalinity of its carbonate. It is the oxide of a white metal which has been named *lithium;* the equivalent of which is 10, and that of lithia 18.

LITHI'ASIS. (Gr. λιθος, *a stone.*) The disease of stone in the bladder or kidney.

LITHIC ACID. (Gr. λιθος.) The substance generally termed *uric acid:* it forms the commonest variety of urinary calculus.

LITHODENDRON. (Gr. λιθος, and δενδρον, *a tree.*) Corals have been thus designated, from their frequent arborescent appearance.

LITHODE'RMIS. (Gr. λιθος, and δερμα, *skin.*) A genus of Apodal Echinoderms, in the system of Cuvier; characterized by an oval body compressed posteriorly, of which the surface is covered with a layer of calcareous granules, which form an extremely indurated crust.

LI'THODOMES, *Lithodoma*. (Gr. λιθος, and δεμω, *I build.*) This term is applied to those bivalves which are found in rocks and stones, inhabiting cavities, which they form for that purpose. A particular genus is called *Lythodomus*.

LITHO'DOMI. (Gr. λιθος, and Lat. domus, *a house.*) Molluscous animals which bore into rocks and lodge themselves in the holes.

LITHO'GRAPHY. *See* ENGRAVING.

LITHOLO'GICAL. (Gr. λιθος, and λογος, *a discourse.*) A term expressing the stony structure or character of a mineral mass. We speak of the *lithological* character of a structure, as distinguished from its *zoological* character.

LI'THOMANCY. (Gr. λιθος, and μαντεια, *prophecy.*) A species of divination practised by the ancients. Their oracular stones appear to have returned audible answers to those who consulted them. Modern conjurors have

another species of lithomancy, — the inspection of the surface of smooth agates or crystals. Such was the divination of the notorious Dr. Dee and his assistant Kelly in the reign of Queen Elizabeth.

LI'THOMARGE. Stone-marrow. A variety of talc of various colours, and generally associated with magnesian minerals.

LI'THONTRI'PTICS. (Gr. λιθος, and τριβω, *I carry away.*) Remedies which are supposed to dissolve stone in the bladder, or which prevent the deposition of calculous matter in the urine.

LI'THONTRI'PTOR. (Gr. λιθος, and θρυπτειν, *to break.*) An instrument for breaking calculi in the bladder, so as to reduce them to small particles which may admit of being passed along with the urine, and thus render the operation of lithotomy unnecessary.

LITHO'TOMY. (Gr. λιθος, and τεμνω, *I cut.*) The operation of cutting into the bladder for the removal of a stone.

LITHO'TRITY. (Gr. λιθος, and τειρω, *I break down.*) The operation of breaking a stone in the bladder into small pieces capable of being voided by urine: it is effected by the introduction of instruments by the urethra.

LI'TMUS. In Chemistry, a blue pigment obtained from the lichen *Rocella*, which grows in the Canary Islands: it is often called *turnsol*, and yields the dye called *archil*. Paper tinged blue by litmus is reddened by the feeblest acids, and hence is used as a *test* of the presence of acids; and litmus paper which has been reddened by an acid has its blue colour restored by an alkali.

LI'TOTES. (Gr. λιτοτης.) In Rhetoric, a figure, according to the Greek and Latin rhetoricians, in which an affirmative is expressed by the negative of the contrary: it is, therefore, a species of irony in the ancient sense of the word (*see* IRONY), in which less is expressed than what is intended to be conveyed to the mind of the reader or hearer. Thus, "a citizen of no mean city" means "of an illustrious city." It is a figure constantly employed to soften what might otherwise appear obnoxious in self-commendation.

LI'TRE. The French standard measure of capacity in the decimal system. The litre is a cubic decimetre; that is, a cube, each of the sides of which are 3·937 English inches: it contains 61·028 English cubic inches, and is therefore rather less than our *quart*. Four and a half litres are a close approach to the English imperial *gallon*.

LI'TTLE. (Sax. lytel.) In the Fine Arts, a term denoting that a work is void of those qualities that tend to raise the feelings of the spectator in contemplating a work of art. It is a term always used in a condemnatory sense.

LITTORI'NA. (Lat. litus, the *sea shore.*) A genus of Pectinibranchiate Mollusks of the tribe *Trochoida;* characterized by its thick shell, of which the aperture presents a small angle, and is without a ridge. The common periwinkle of our coasts (*Turbo littoreus*, Linn.) is a species of the present genus.

LI'TURGY. (Gr. λειτουργια.) An office at Athens, by which persons of considerable property were bound to perform certain public duties, or supply the commonwealth with necessaries at their own expense. The persons on whom this office was imposed were usually among the richest inhabitants; and if any one selected to fill it could find another more wealthy than himself who was exempt from public duty, he could insist on being released from his charge, which then devolved on the party denounced. This obnoxious institution was abolished on the proposition of Demosthenes. (See *Boeckh's Public Economy of Athens.*) It is from this term that the English *liturgy* (quod vide), in ecclesiastical meaning, has been derived; the sense having been contracted from public *ministry* or service in general to the ceremonies of religious worship.

LITURGY. The ritual according to which the religious services of a church are performed. In the writings of the ancients the name is restricted to the service of the Eucharist, which afterwards came to be distinguished in the Western church by the term *missa*, or mass.

There still exist in Greek, Latin, and some Oriental languages, various rituals by which the Eucharist was celebrated in very early ages. Some have supposed that all these may be referred to one original liturgy, which may have been universally adopted in the primitive church. Palmer, the latest English writer on this subject (*Antiq.* vol. i. p. 8.), conceives that the number of original liturgies may be reduced to four, but not lower. These he entitles the great Oriental liturgy, the Alexandrian, the Roman, and the Gallican; each of which was extensively used from the apostolic age in the quarters from which he assigns them their names, and became the parents of many other rituals, such as were used, with constantly diverging variations, in the different patriarchates of the empire.

The earliest period at which any liturgical forms were consigned to writing is the end of the third or beginning of the fourth century; at least the liturgy called of St. Basil can be traced as high as the latter period. This practice, also, seems frequently to have been applied only to certain parts of the service. We find, therefore, great differences in the MSS. which now exist; and it becomes very difficult to ascertain what the contents of the primitive rituals were, and trace the periods at which many rites and ceremonies have been introduced into the service.

The liturgy of the church of England is a liturgy in the wider and more usual acceptation of the term, comprehending the whole of the various services used on ordinary and extraordinary occasions throughout the year. For the history of this liturgy, see COMMON PRAYER. See also Assemanni, *Codex Liturgicus;* Muratori, *Liturgia Romana Vetus; Breff's Collection of Liturgies; Palmer's Origines Liturgicæ; Riddle's Christian Antiquities*, pp. 369. 377. As to the reforms in the English liturgy, which were seriously contemplated a few years ago by various classes of the church, see *Quart. Review*, vols. xlvii. l.

LITUUS. (Lat.) In the geometry of curve lines, the name given by Cotes to a spiral; of which the characteristic property is that the squares of any two radii vectores are reciprocally proportional to the angles which they respectively make with a certain straight line given in position, and which is an asymptote to the spiral. Let r and u denote any two radii vectores drawn from the pole to the curve, and let φ and ψ be the measures of the angles they respectively make with the asymptote; then $r^2 : u^2 : : \psi : \varphi$. If we take the angle $\psi = 57{\cdot}29578^\circ$ (or such that the arc is equal to the radius), and call a the corresponding value of u, the above proportion becomes $r^2 : a^2 : : 1 : \varphi$; whence we have for the equation of the curve, $r^2 = a^2\varphi^{-1}$

Among the properties of the curve are the following: — 1. The radius vector is reciprocally proportional to the circular arc intercepted between its extremity and the asymptote. 2. The area included between the two radii vectores a and r and the curve is equal to a^2 log. $(u \div a)$; or proportional to the logarithm of the ratio of u to a.

For the properties of the lituus see Varignon, *Mem. Acad. Paris*, 1704; Cotes, *Harmonia Mensurarum*, p. 85.; *Peacock's Examples to the Diff. and Integral Calculus*, p. 183.

LI'TUUS. Among the Romans, a crooked staff, resembling a crozier, made use of by the augurs in quartering the heavens. It is affirmed by Dr. E. D. Clarke, that the use of the *augural* lituus, as it was called, is much posterior to that of the *regal* or *quirinal* lituus, which was instituted by Romulus, and used as a sceptre by the Roman kings; and that they had nothing in common except the name. The origin of the word is uncertain. (See *Clarke's Observations on the "Lituus," in the Archæolog.* xix. p. 386.)

LI'VER. (Germ. leber.) The viscus in which bile is secreted. It is situated in the right hypochondriac region under the diaphragm; and in the human body is divided into two lobes, of which the right lobe is the largest. There is between them a smaller lobular process, called the *Lobulus Spigelii*. The ultimate arrangement of the different blood-vessels of the liver is very peculiar. It has been ably investigated by Mr. Kiernan, by whom it is described in the *Philosophical Transactions*.

LI'VER OF SULPHUR. Fused sulphuret of potassium: so called from its *liver colour*.

LI'VERY. (Fr. livree.) A word derived, probably, from the clothes *delivered* by masters to their servants, in which sense it still continues to be used. At tournaments the cavaliers used to distinguish themselves by wearing the livery or badge of their mistresses; and persons of distinction formerly gave liveries to persons unconnected with their own household or family, to engage them in their quarrels for the time being. The *liverymen* of London are a number of men belonging to the freemen of the ninety-one companies, which embrace the different trades of the metropolis; and are so called because they are entitled to wear the livery of their respective companies. By this body are elected the common-councilmen, sheriffs, aldermen, and some other superior officers of the city; and, down to the passing of the Reform Bill in 1832, they had the exclusive privilege of voting at the election of members of parliament.

LI'VERY OF SEISIN. In Law, a delivery of possession in lands, tenements, and hereditaments, to one that has a right to the same: a ceremony at common law used in the conveyance of lands, whereby an estate of freehold passes by feoffment. *See* FEOFFMENT.

LIVE STOCK. The quadrupeds and other animals kept in a farm for the purpose of being employed in farm labours, for breeding, for being fattened, or for other purposes of profit. In the farming of Britain and similar climates the principal descriptions of live stock are horses, cattle, sheep, and swine; but to these are generally added poultry, and sometimes goats, rabbits, fish, and bees. In warmer climates the silkworm may be considered as part of the live stock; and under particular circumstances, both in England and on the Continent, deer, and even hares and pheasants, are bred for sale.

LIVING FORCE. *See* FORCE.

LI'VRE. (Lat. libra, *a pound.*) An ancient French

coin, which appears as early as 810 A.D. It was at first divided into 20 *solidos*, and afterwards into 20 *sous*. At the French revolution the *franc* was substituted for the livre.

LIXI'VIUM. A term employed by the old chemists to signify an alkaline ley or solution.

LIZARD. *See* LACERTA.

LLOYD'S LIST. A well-known periodical publication, which contains a full account of shipping intelligence. It derives its name from Lloyd's coffee-house, so long celebrated as the resort of all classes connected either with the mercantile or shipping interest; and its importance in supplying full, trustworthy, and early maritime information cannot be easily overrated. It has been in existence since 1716.

LOA'DSTONE. The same with *magnet*, which see.

LOA'MY SOIL, in the language of practical agriculturists and gardeners, is one in which clay prevails: it is called heavy or light, as the clay may be more or less abundant; and sandy, gravelly, or calcareous, according as these earths predominate in the composition. In general, loamy soils are more fertile than sand or chalk; but the fertility of any soil is always to a certain extent relative to the nature of the subsoil, and to the local climate.

LO'BATE. (Lat. lobus, *a lobe*.) A term applied by Linnæus to the feet of those birds, as the grebe, which were furnished at their sides with broad-lobed membranes.

LO'BBY. (Ger. laube, *an arbour*.) In Architecture, a hall or passage serving as an ante apartment for communication to rooms.

LOBE'LIA INFLATA. Indian tobacco. The leaves of this plant have been used in medicine as an expectorant and emetic: it quiets the action of the heart, and relaxes the muscles. It has been found of great use in allaying the paroxysms of spasmodic asthma, and as a relaxant in hooping-cough.

LO'CAL PRO'BLEM (Lat. locus), in the ancient Geometry, is a problem which admits of an infinite number of solutions, or which can be solved not only by a single point, but by all points situated in some line which may be found. *See* LOCUS.

LOCH. The Scotch term for *lake*, which see. See also LOUGH.

LOCK, in Internal Navigation, is a part of a canal included between two floodgates, by means of which a vessel is transferred from a higher to a lower level, or from a lower to a higher. *See* CANAL.

LOCK. (Saxon, loc.) An instrument composed of springs and bolts, used to fasten doors, drawers, chests, &c. A good lock is the masterpiece in smithery, and requires much art and delicacy in contriving and varying the wards, springs, bolts, and other parts whereof it is composed, so as to adjust them to the places where they are serviceable and to the various occasions of their use. The structure of locks is so varied, and the number of inventions of different sorts so extended, that we cannot attempt to enumerate them. Those placed on outer doors are called *stock* locks, those on chamber doors spring locks, and such as are hidden in the thickness of the doors to which they are applied are called *mortice* locks. The padlock is too well known to need description. We here add the conditions which, to Mr. Nicholson, appear necessary in a lock of the most perfect kind: — 1. That certain parts of the lock should be variable in position through a great number of combinations, one only of which shall allow the lock to be opened or shut. 2. That this last-mentioned combination should be variable at the pleasure of the possessor. 3. That it should not be possible, after the lock is closed and the combination disturbed, for any one, not even the maker of the lock, to discover, by any examination, what may be the proper situations of the parts required to open the lock. 4. That trials of this kind shall not be capable of injuring the works. 5. That it shall require no key; 6. And be as easily opened in the dark as in the light. 7. That the opening and shutting should be done by a process as simple as that of a common lock. 8. That it should open without a key, or with one, at pleasure. 9. That the keyhole be concealed, defended, or inaccessible. 10. That the key may be used by a stranger, without his knowing or being able to discover the adopted combination. 11. That the key be capable of adjustment to all the variations of the lock, and yet be simple. 12. That the lock should not be liable to be taken off and examined, whether the receptacle be open or shut, except by one who knows the adopted combination. These considerations involve a mechanical problem of great difficulty; but much towards its accomplishment has been effected in various inventions that have been promulgated, and more especially in those of Bramah, Chubbs, Taylor, &c.

LO'COFO'COS. The name by which the ultra democratical or the tory party in America has been distinguished since the year 1834. The term originated in the following incident. Some of that party having had a meeting at Tammany Hall, near New York, the lamps were accidentally extinguished; and on the hall being relighted with lucifers (which in America are termed *locofocos*, probably from the Lat. loco foci, *instead of a fire*), the word was adopted as a distinguishing appellative, and is now of universal application.

LO'COMO'TION. (Lat. loci motio, *change of place*.) Such motion as is attended by change of place in the body which moves, in contradistinction to motions which a body may have which is stationary. Thus, a clock, a mill, a lathe moves; but no change of place of the machine is produced: such *motion* is not locomotion. A steam engine which, being fixed in its position, impels other bodies is a stationary engine; but one which travels with the bodies which it drives is called a *locomotive* engine.

LOCOMOTIVE ENGINE. Any engine which, being employed to draw loads in transport overland, travels with the load which it draws.

Since the improvement and extension of iron railways, this term has been exclusively applied to the steam engines, by which loads are drawn upon them. Although, strictly speaking, the steam engine by which a ship is propelled is a locomotive engine, it is not usual to apply that term to it; such an engine is called a marine engine. (*See* STEAM NAVIGATION.) The term locomotive engine must, therefore, as at present used, be understood to express the travelling steam engine by which trains are drawn on railways.

History of the Locomotive Engine.—The first practical application of the steam engine as a locomotive power took place in 1804, on a railroad at Merthyr Tydvil, in South Wales. The engine was constructed by Messrs. Trevethick and Vivian, under a patent obtained by them two years previously. This engine, in several respects, resembled in its form and structure those which have been since used for a like purpose.

The boiler was a cylinder, with flat circular ends placed upon its side. A large tube entered it at one end, and, being carried near the other, was there received and carried back parallel to its first direction; its course through the boiler resembling the letter U. The two mouths or openings of this tube were therefore placed at the same end of the boiler. One of the mouths of this tube communicated with the chimney, the base of which was flanged upon it, and the other contained the grate and furnace. The flame and heated air were drawn through the curved tube, and up the chimney. The engine was worked by high-pressure steam without condensation; the steam being admitted to the cylinder, and withdrawn from it, by the well-known mechanical contrivance called a four-way cock. The cylinder was placed on its side; and in one position of the cock a communication was opened between the boiler and one end of the cylinder, while another communication was opened between the other end of the cylinder and a tube leading to the chimney. Steam was thus admitted to act on one side of the piston, and allowed to escape from the other side to the chimney. When the piston attained the end of the stroke, the position of the cock was reversed, and the steam which had just driven the piston in one direction was allowed to escape to the chimney, while steam from the boiler was admitted on the other side of the piston, to impel it in the contrary direction; and in this manner the piston was continually driven backwards and forwards, in a horizontal direction, and parallel to the direction of the load. The piston rod was moved through a hole, corresponding with it in magnitude, in the cover of the cylinder, in which it was rendered steam-tight by a stuffing box properly lubricated. This piston rod acted by means of a connecting rod on a crank, which it kept in revolution in the same manner as the crank in a common double-acting steam engine is moved. (*See* STEAM ENGINE.) On the axle of this crank was placed a cogged wheel, which, by means of ordinary gearing, conveyed motion to the axle of the hind wheels of the engine, so as to keep that axle in constant revolution. The wheels being keyed upon that axle, so as not to be capable, like the wheels of a common carriage, of turning upon it, were necessarily made to revolve with it; and, so long as their pressure upon the road was sufficient to prevent them from slipping, a progressive motion of the carriage was the necessary consequence of their revolution.

The early projectors of locomotive engines were all impressed with a notion that the adhesion of the driving wheels with the rails must be insufficient to enable the power applied to these wheels to give progressive motion to the carriage; and, without thinking it necessary to ascertain by actual experiment, whether such were really the case or not, they expended much ingenuity and capital in devising means of overcoming this difficulty, which, after all, turned out to be merely imaginary. Engineers were, in fact, impressed with a notion that if any power compelled the wheels to revolve, they would merely slip upon the rails, and that the carriage or engine would remain stationary. To provide against this, Messrs. Trevethick and Vivian proposed to make the external rims of the wheels intended for common roads rough and uneven, by surrounding them with projecting

heads of nails or bolts, or by cutting transverse grooves in them. Seven years afterwards Mr. Blinkensop, of Leeds, obtained a patent for a method of surmounting his imaginary difficulty, by the substitution of a rack rail for the ordinary smooth rail, and constructing teeth on the driving wheels to work in the teeth of this rack. Various other ingenious contrivances were subsequently produced for the same purpose, until about the year 1814, when experience at length forced upon engineers the knowledge of the fact, that the adhesion of the tires of the wheels with the rails was amply sufficient to propel the engine, even when drawing after it a great load.

In 1814, an engine was constructed at Killingworth colliery, near Newcastle, having two cylinders with a cylindrical boiler, and working two pair of wheels by cranks placed at right angles, so that, when one was in full operation, the other was at its dead points. By these means the propelling power was always in action. The cranks were maintained in this position by an endless chain, which passed round two cog wheels placed under the engine, and fixed on the same axles on which the wheels were placed. The wheels in this case were fixed on the axles, and turned with them.

In an engine subsequently constructed by Mr. Stevenson for the same railway, the mode adopted of connecting the wheels by an endless chain and cog wheels was abandoned, and the same effect was produced by connecting the two cranks by a straight rod. This method is still used in the coupled engines which are applied to draw the trains of merchandise on the present railways.

The next stimulus which the progress of this invention received arose from the project of constructing a railway between Liverpool and Manchester, for the purposes of general traffic. When this project was undertaken it was not decided what moving power was most eligible—whether horse power, stationary steam engines, or locomotive engines; but the first, for many obvious reasons, was soon rejected, in favour of one or other of the last two.

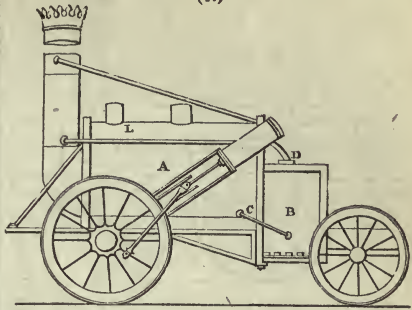
The steam engine may be applied to move carriages on a railway by two distinct methods. By one, the engine is fixed, and draws a train of carriages towards it, by a rope extending the whole length of the road on which the engine works. By this method the line of road is divided into a number of short stages, at the extremity of each of which an engine is placed. The waggons or carriages, when drawn by any engine to its station, are detached, and connected with the extremity of the rope-work by the next stationary engine, and thus the journey is performed from station to station by separate engines. For a more detailed account of this method of working a railway, see STATIONARY ENGINE. By the other method, each load transported along the line is drawn by an engine which travels with it as horses travel with a carriage on a common road.

To enable them to decide which of these two methods of working the proposed railway it would be most advisable to adopt, the directors of the Liverpool and Manchester line employed Messrs. Stevenson and Locke, and Messrs. Walker and Rastrick, experienced engineers, to visit the different railways then in operation, to obtain the results of the experience which they afforded as to these two methods of applying steam power to transport, and to report their opinion on the relative merits of the two methods. After an elaborate inquiry, the decision of the directors was given in favour of locomotive power.

Until the period to which we now advert, railways had been almost exclusively confined to the transport of mineral products from the mines up to the places of shipment, and to this purpose exclusively had the locomotive engine been applied; but the ends to be attained by a railway of thirty miles in length, connecting the largest manufacturing town, in the greatest manufacturing country in the world, with the greatest, most active, and most opulent commercial port, were of a nature so much more extensive and important, that it was considered that more than ordinary means should be resorted to to obtain a moving power commensurate with the traffic which might be expected under such circumstances. Prizes were therefore proposed to be given, under certain stipulations, to those who would construct the most effective locomotive engines for the purposes of the road.

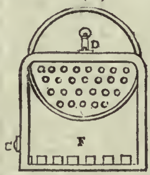
This proposal produced, as was anticipated, much competition; and the spirit of emulation being roused, a trial was appointed, which took place on the railway in October, 1829. Engines of several forms were produced; and the prize was awarded to one, called the *Rocket*, constructed by Mr. Robert Stevenson, the son of Mr. George Stevenson, the engineer of the railway. In the first trial, this engine attained the then astonishing speed of twenty-nine miles an hour; and when, unhappily, at the ceremony of the opening of the railway, the accident occurred which deprived the country of Mr. Huskisson, his wounded body was conveyed, by the same engine, a distance of about fifteen miles in twenty-five minutes, being at the rate of thirty-six miles an hour. This engine, which involved in its construction all those mechanical arrangements to which the extraordinary speed and power of the locomotive engine of the present day are due, is represented in elevation in fig. 1.; and a cross section

(1.)



of the boiler and furnace is represented in fig. 2. It is supported on four wheels, the weight being principally thrown on the larger pair worked by the engine. The boiler is a cylinder 6 feet long, having the chimney at one end, and the fire-box B at the other. This box is surrounded with a hollow casing, which communicates with the bottom of the boiler by a tube C, and with the top by a tube D. The water in the boiler, therefore, flows into the casing, and fills it to the same level as that which it has in the boiler. When the engine is at work, the boiler is kept about half filled with water, and, consequently, the casing round the furnace is completely filled. Steam is abundantly generated in this casing, exposed as it is on every side to the radiant heat of the fire: this steam rises in bubbles, and passes through the tube D into the boiler. The lower part of the boiler is traversed by a number of copper tubes, the ends of which appear in fig. 2. The flame and heated air proceeding from the burning fuel pass through these tubes, and, after traversing the whole length of the boiler, escape into the chimney, imparting, on their passage, heat to the water in the boiler. The necessary draught through the furnace is maintained by causing the cylinders to discharge the waste steam into a pipe, which is presented up the chimney, and is called the blast pipe. There are two cylinders placed outside the engine, on either side of it, as represented in fig. 1.: they are placed in a diagonal position, and their rods move in guides; the end of the piston rod is connected with one of the spokes of the wheels by a connecting rod, and the piston, as it is driven by the steam in each direction in the cylinder, causes the wheels to revolve.

(2.)



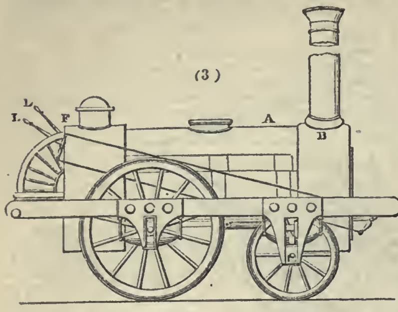
The circumstances in this mechanical arrangement, on which the rapid production of steam depends, are two-fold: first, the extensive surface exposed to the radiant heat of the fire, by the casing surrounding the fire box, and by the tubes, twenty-five in number and only three inches in diameter, by which the flame and heated air are conducted through the boiler from the fire box to the chimney; and, secondly, by the powerful draught maintained in the furnace by the current of steam constantly discharged up the chimney. It has been mainly by bringing these principles more fully into operation, that all the improvements since made in the locomotive engine have been effected.

The railway was not not long in operation, when the arrangement of the tubes in the boiler was improved; their number was increased from twenty-five to one hundred and upwards, and their diameters diminished from three inches to an inch and a half. This change alone produced an increased efficiency of the fuel, in the proportion of nearly two to one; the consumption of coke in the Rocket having been very nearly $2\frac{1}{2}$ pounds per ton per mile, while, by the change above mentioned, the consumption of fuel in the new engines was reduced to $1\frac{1}{4}$ pound per ton per mile. The position of the cylinder was also advantageously changed. Instead of being placed, as in the Rocket, outside the boiler, and exposed to the cold air, through which the engine passed with such a velocity, they were now placed in that part of the engine called the *smoke box*, an enclosed space at the base of the chimney, into which the flame and heated air escaping from the tubes passed. By this arrangement the cylinders were always maintained as hot as the air which issued from the flues, and all condensation of steam by their exposure prevented.

X x

The engine in this improved form is represented in fig. 3. As the cylinders were now placed between the

(3)

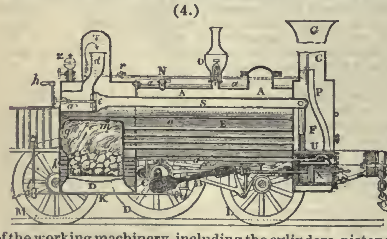


wheels, their operation could not be effected in the same manner as in the Rocket. The connecting rods were accordingly made to act on two cranks, constructed upon the axle of the wheels, placed at right angles to each other, so that one may always be at its dead point, while the other was in full action. This double-cranked axle was, from the weakness consequent upon its form, liable at first to fracture; but improved methods of forging them subsequently gave them sufficient strength, and now the fracture of a cranked axle rarely occurs.

The two chief improvements in the locomotive engine, which succeeded those now explained, and which brought that machine to its present state of efficiency, consisted, first, in the substitution of brass for copper tubes; and, secondly, in the addition of another pair of wheels to support the engine. It was found, by continued experience, that the copper tubes, from some peculiar action of the fire upon them, which has never been explained or understood, were subject to rapid decay; and in the year 1833, after an experience of about three years of the working of these engines, it occurred to Mr. Dixon, then one of the superintendents of the engineering department of the Liverpool and Manchester railway, to try the effect of brass tubes. The experiment was eminently successful: they were found to last six or eight times as long as copper tubes of the same dimensions. Having now brought down the history of the locomotive engine to the present time, we shall give a description of one of these machines in its most improved form.

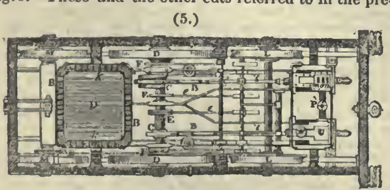
Description of the most improved Locomotive Engine in operation in 1840. — A longitudinal vertical section of a locomotive engine is represented in fig. 4.; and a plan

(4.)



of the working machinery, including the cylinders, pistons, eccentrics, &c., which are under the boiler, and by the operation of which the engine is driven, is represented in fig. 5. These and the other cuts referred to in the pre-

(5.)



sent article have been taken, with the permission of the author and publishers, from the 7th edition of Dr. Lardner's work on the Steam Engine; to which the reader is referred for a more detailed account of the history, the structure, and the operation of the locomotive engine, than the limits of the present article will allow us to supply.

The boiler, as has been explained in the engines already described, is a cylinder placed upon its side; the fire box consists of two casings of metal, one within the other, bolted together by rivets, represented at *k*; the fire grate is represented at D. The fire door is represented at *g*, opening upon the platform where the engineer stands. It will be perceived in the section fig. 4., as well as in the plan fig. 5., that the fire box is on every side surrounded by the water contained between the two casings, the level of the water in the boiler being above the roof of the fire box. The tubes by which the flame, and the products of combustion, are drawn from the fire box into the smoke box are represented at E, fig. 4. The smoke box containing the cylinders and blast pipe, and supporting the chimney, is represented at F. In the engine from which this drawing was taken the boiler is a cylinder 7½ feet long and 3½ feet diameter; it is clothed with a boarding of wood, represented at *a*, and bound round by iron hoops screwed together at the bottom. Wood being a slow conductor of heat, this covering has the effect of keeping the boiler warm and checking the condensation of steam.

The external casing of the fire box, B B, is nearly square in its plan, as seen in fig. 5., being 4 feet wide, and 3 feet 7½ inches long: it is constructed of wrought-iron plates, and descends two feet below the boiler, as seen in fig. 4.; the top being semi-cylindrical, of a diameter greater than that of the boiler, and concentrical with it. The inner casing, *k k*, fig. 5., is similar in shape to the external; but it is lower, and flat at the roof, as seen in fig. 4. The space between the two casings is from 3 to 4 inches in width. This internal fire box is made of copper plates.

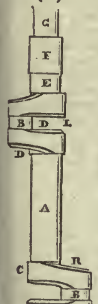
As the top of the fire box would be liable to be destroyed by the action of the fire if the level of the water in the boiler were suffered to fall below it, so as to leave it uncovered, a leaden plug *m* is inserted in it, which would melt out before the copper would become injuriously heated, and the steam rushing out at the aperture would cause the fire to be extinguished. The tubes E, which serve to conduct the flame through the boiler to the smoke box, are made of the best rolled brass, $\frac{1}{13}$th of an inch thick, and $1\frac{5}{8}$ of an inch in external diameter; they are 124 in number, and the distance between tube and tube is three quarters of an inch. The number of these tubes is at present seldom less than 90, and varies between that and 150. The tubes act as stays, connecting the ends of the boiler to strengthen them; but besides these there are rods of wrought iron, represented at *o*, fig. 4., which extend from end to end of the boiler, above the roof of the fire box. The smoke box F, containing the cylinders, steam pipe, and blast pipe, is 4 feet wide, and 2 feet long: it is formed of wrought-iron plates, rivetted in the same manner as those of the fire box. From the top of the smoke box, which, like the fire box, is semi-cylindrical, rises the chimney G, 15 inches diameter, made of ⅛-inch iron plates, rivetted and bound round by hoops. Near the bottom of the smoke box the working cylinders are placed side by side, in a horizontal position, with the slide valves upwards, as seen in fig. 5.

At the top of the external fire box, fig. 4., a circular aperture is formed 15 inches in diameter; and upon this aperture is placed the steam dome T, 2 feet in height, and secured to the aperture by nuts. The steam dome is made of brass, nearly half an inch thick. A funnel-shaped tube *d*, with its wide end upwards, is flanged upon the side of the great steam pipe S, and is carried upwards, so that its mouth is near the top of the steam dome T. In order to pass into the steam pipe S, the steam which fills the upper part of the boiler A must ascend the steam dome and enter the funnel *d*, as indicated by the bent arrow in fig. 4. This arrangement prevents, in a great degree, the effect of priming, by which word is expressed technically the spray of water which rises from the water of the boiler, and is mixed with the steam in the upper part of it: as the steam ascends the steam dome this spray falls back, and nothing but pure steam enters the funnel *d*. The wider part of the great steam pipe S is flanged, and screwed at the hinder end to a corresponding aperture in the back of the fire box, where the engineer stands: this opening is covered by a circular plate, secured by screws, having a stuffing box in its centre, of the same kind as is used for the piston rods of steam cylinders. Through this stuffing box the spindle or rod *a′* of the regulator passes; and to its end is attached a winch *h*, by which the spindle *a′* is capable of being turned. To the other end of this spindle, at *e*, is attached a plate, which moves upon apertures formed in the cover of the end of the great steam pipe S; so that, by turning the winch *h* more or less, this plate *e* may be removed more or less from over the openings; and thus the steam may be allowed to enter the steam pipe S from the steam dome T in greater or less quantity, or may be shut off altogether. The steam pipe S, being enclosed within the boiler, is maintained at the same temperature as the steam in the boiler; and therefore the steam, in

passing through it, is not liable to condensation. The steam pipe, passing through the tube plate at the front of the boiler, is turned down at right angles in the smoke box, where, dividing into two branches, one is conducted to each of the valve boxes of the cylinders. The lower ends of these branches are flanged to the valve boxes at the ends of the cylinders nearest to the boiler: by these pipes the steam is conducted into the valve boxes, or steam chests, from which it is admitted by slide valves to the cylinders to work the pistons. On the upper sides of the cylinders are the steam chests U, communicating with the passage; *m*, fig. 5., leading to the top of the cylinder, *n* leading to the bottom, and *o* leading through the side pipe P′ to the blast pipe. These openings are governed by a slide, so that, when steam is admitted through *m*, the communication shall be opened between *n* and *o*. Thus, when steam is admitted to the top of the cylinder, the steam from the bottom will flow from *n*, through *o*, into the blast pipe. When the piston reaches the bottom of the cylinder, then the slide opens a communication between *n* and the steam pipe, and between *m* and *o*. Thus steam will be admitted to the bottom of the cylinder, while the steam from the top will escape from *m*, through *o*, to the blast pipe. In this way, by the alternate shifting of the slide, steam is admitted alternately to each end of the cylinder, and allowed to escape from the other end, and the alternate motion of the piston and the cylinder is thereby maintained. The pistons used in locomotive engines are of the kind called metallic pistons, and, from their horizontal position, they have a tendency to wear unequally in the cylinders, their weight pressing them on one side only; but, from their small magnitude, this effect is found to be imperceptible in practice. The cross pipe P′, which communicates with the eduction passage *o*, in each of the valve boxes, has an opening in the centre presented upwards, as seen in fig. 5. To this opening is flanged the base of the blast pipe *p*, fig. 4., which rises in a direction slightly curved, and has its mouth presented upwards in the centre of the chimney G. The steam which is discharged at each stroke of the pistons from the cylinders passes through this pipe, and escapes up the chimney by puffs. When an engine is moving slowly, these puffs are distinctly audible, resembling the coughing of a horse; but when at full speed, they succeed each other so rapidly that the ear can scarcely distinguish their intervals. It is this stream of waste steam, continually rushing up the chimney, that maintains the necessary draught in the fireplace; the upper current thus produced in the funnel causes a corresponding current into the smoke box F, through the tubes E; and there is this excellence in the arrangement, that the force of the draught in the chimney being proportional to the quantity of steam produced, it must be therefore proportional to the quantity of fuel necessary to be consumed.

The force of the steam thus impressed upon the pistons is communicated by the piston rods Y, fig. 4., the cross heads of which move in guides to the connecting rods B, which are attached to the crank pins of the working axle C; so that, as the piston rods are driven backwards and forwards in the cylinders, the working axle is made to revolve. This axle, with the two cranks formed upon it, is represented in fig. 6., where the two cranks must be understood to be in a position at an angle of 45° with the plane of the figure, and therefore at an angle of 90° with each other. As this axle is the instrument by which the impelling force is conveyed to the load, and as it has to support a great portion of the weight of the engine, it is constructed with great strength and precision. Its length is 6½ feet, and its diameter 5 inches. At the centre part A it is cylindrical, and is increased to 5½ inches at C, where the cranks are formed. The sides D of the cranks are 4 inches thick; and the crank pins B, which are truly cylindrical, are 5 inches in diameter and 3 inches in length. Upon the parts F, which are 7½ inches long, the great driving wheels D, fig. 4., are firmly fastened, so as to be prevented from turning or shaking upon the axle. Brasses are fixed on the outside frame of the engine, which rest upon these projections G of the axle; and upon these brasses the weight of the engine is supported.

(6.)



The strength and accuracy of construction necessary for these axles render them expensive: they cost about 50*l*. each. They are seldom broken, but sometimes bent when the engine escapes from the rails.

The method by which the slides are made to govern the admission and escape of the steam to and from the cylinders is nearly the same as in the steam engine used for the general purposes of manufacture; and for a general description of the method see Steam Engine. Meanwhile it may be here briefly stated, that this is effected by two circular plates called eccentrics, fixed at E E, fig. 5., on the great working axle. These eccentrics are circular plates or rings, formed upon or attached to the axle so as to revolve in their own plane, forming, in effect, a part of the axle itself; but they are so placed that their centres do not coincide with the centre of the axle, and, consequently, as they revolve with the axle, their centres are alternately thrown backwards and forwards, as they pass on the one side or the other of the axle. These circular plates are surrounded by rings, within which they revolve, but which do not revolve with them. These rings are alternately thrown backwards and forwards by the play of the eccentrics; and to these rings are attached rods *e e*, which communicate motion to the arms which drive the rods of the slides. Thus the alternate motions of the eccentrics backwards and forwards proceed from the working axle, produce a corresponding backward and forward motion in the slides, and thereby govern the admission and escape of the steam to and from the cylinders. When it is required to reverse the motion of the engine, or to make it move backwards, the motion of the slides, and therefore the positions of the eccentrics on the working axle, must be the contrary of that necessary to produce a progressive motion. Sometimes this is effected by shifting the position of the eccentrics on the working axle; but more commonly it is effected by a second pair of eccentrics, represented at F F, fig. 5., placed on the axle in a position contrary to the others. When the engine is driven backwards, the eccentrics E E are thrown out of gear, and the eccentrics F F are brought into action.

As all the moving parts of the engine require to be constantly lubricated with oil, to diminish the friction and keep them cool, oil cups for this purpose are fixed upon them. In some engines these oil cups are attached separately to all the moving parts; in others they are placed near each other in a row on the side of the boiler, and communicate by small tubes with the several parts to be lubricated.

The tender is a carriage attached behind the engine, and close to it, carrying coke for the supply of the furnace, and a tank containing water for the boiler. The feed for the boiler is conducted through a curved pipe proceeding from the tank, and carried first downwards, and afterwards in a horizontal direction, as represented at K, fig. 4., under the boiler. It communicates with a forcing pump, which is worked by an arm driven by the cross head of the steam piston. By this pump water is constantly forced into the boiler, so long as the pump is kept in communication with the tank; but this communication may be opened and cut off by a cock *l*, governed by the engineer. As the feed of the boiler by the introduction of cold water checks the activity of the evaporation, it is the custom not to feed the boiler regularly and constantly, but to throw on the feed when the work on the engine is light and the consumption of steam small, and to shut it off when much steam is required. The circumstances of a railway naturally suggest this. When the engine is ascending an incline all the steam which the boiler is capable of producing is required, and therefore the activity of the boiler is stimulated by shutting off the feed; but in descending an incline less power is required, and the feed is put on.

Until within the last few years, locomotive engines were supported on only four wheels. It is now, however, the general practice to place them on six, the driving wheels being in the middle, as represented in fig. 4. To give greater security to the position of the engine between the rails, it is usual to construct flanges on the tires of all the six wheels. Mr. Stevenson, however, has been in the practice of constructing the driving wheels without flanges, and with tires truly cylindrical, depending on the flanges of the two pairs of smaller wheels to maintain the engine between the rails. The wheels of the engine represented in fig. 4. are constructed in this manner. The driving wheels D are fixed on the cranked axle C, and are constructed with cylindrical tires without flanges. They are 5 feet in diameter. The wheels L are 3 feet 6 in. in diameter, and have conical tires with flanges. They are placed immediately behind the smoke box. The wheels M are precisely similar to L, and are placed immediately behind the fire box.

When an engine is required for the transport of very heavy loads, such as those of merchandise, the adhesion of one pair of working wheels is insufficient; and, in such cases, one of the two pairs of wheels L or M is made of the same diameter as the driving wheels, and a bar is attached to points on the outside of the wheels, at equal distances from their centre, connecting them in such a manner that any force applied to make one pair of wheels revolve must necessarily impart the same motion to the other pair. By such means the force of the steam is made to drive both pairs of wheels, and consequently a proportionally increased adhesion is obtained.

The speed which an engine is capable of imparting depends on the rate at which the pistons are capable of

being moved in the cylinders. By every motion of each piston backwards and forwards one revolution of the driving wheel is produced; and by each revolution of the driving wheels, supposing them not to slip upon the rails, the load is driven through a distance equal to their circumference. As the two cylinders work together, it follows that a quantity of steam sufficient to fill four cylinders must be supplied by the boiler to the engine, to move the train through a distance equal to the circumference of the driving wheels; and in accomplishing this each piston must move twice from end to end of the cylinder, each cylinder must be twice filled with steam from the boiler, and that steam must be twice discharged from the blast pipe into the chimney. If the driving wheels be 5 feet in diameter, their circumference will be 15 feet 7 inches. To drive a train with a velocity of 30 miles an hour, it is necessary that the engine be propelled through 45 feet per second; and to accomplish this with 5 feet wheels they must make nearly three revolutions per second; and as each revolution requires two motions of the piston in the cylinder, it follows that each piston must move three times forwards and three times backwards in the cylinder in a second; that steam must be admitted six times per second to each cylinder, and discharged twelve times per second through the blast pipe: the motion of the slides and other reciprocating parts of the machinery must consequently correspond.

This rapid reciprocating motion being injurious to the machinery, attempts have been made to diminish it by the adoption of larger working wheels, and the driving wheels on several of the great lines have been accordingly increased to 5½ and 6 feet in diameter. Such engines have not been yet sufficiently long in use to afford a practical estimate of the effects of this change. Experiments of a much bolder kind have been tried on the Great Western Railway, where driving wheels of 10 feet in diameter have been worked. From a course of experiments, however, made by Dr. Lardner with those engines, it did not appear that they had any advantage over those constructed with smaller and lighter wheels. Experience appears to have since confirmed this, as they are now for the most part abandoned. The pressure of steam in the boiler is usually limited by two safety valves, — one represented at N, under the control of the engineer; and the other at O, which cannot be approached by him. The safety valve at N is held down by a lever *r*, which is attached to a spiral spring, and which may, by an adjusting screw, be made to press on the valve with any required force. The second valve O is pressed by several small elliptical springs, placed one above another over the valve, and held down by a screw, which turns in a frame fixed into the valve seat. By this screw the pressure on the valve can be adjusted.

In order to give notice of the approach of the train, a steam whistle Z, fig. 4., is placed immediately above the fire box at the back of the engine. This is an apparatus composed of two small hemispheres of brass, separated one from the other by a small space. Steam is made to pass through a hollow space formed in the lower hemisphere, and escapes from a very narrow circular opening round the edge of that hemisphere. The edge of the upper hemisphere presented downwards encounters this steam, and an effect is produced similar to the action of air in organ pipes. A shrill whistle is produced which can be heard at a great distance, and, differing from all ordinary sounds, never fails to give notice of the approach of a train.

It is not usual to express the power of locomotives, in the same manner as that of other engines, by the term *horse power*. Indeed, until the actual amount of resistance encountered by these machines shall be more certainly ascertained, it is impossible that their efficiency can be estimated. The quantity of water evaporated supplies a major limit to the power exerted; but even this necessary element is not ascertained. Mr. Stevenson states that an engine such as that above described is capable of evaporating only 77 cubic feet of water per hour; but Dr. Lardner found that the mean evaporation obtained by a very accurately conducted experiment over 200 miles of railway, with an engine called the Hecla, similar to the above, was 90 cubic feet per hour very nearly.

But a still greater evaporating power than this is found among the large engines working on the Great Western Railway. In an experiment made by Dr. Lardner with the North Star, drawing 110½ tons gross, at 30½ miles an hour, the evaporation was 200 cubic feet per hour.

On the evaporating power of the engines, other things being the same, must ultimately depend the speed of railway traffic. For it must be apparent that no modification which can be made in the mechanism of the engine, no change in the magnitude of the driving wheels, nor any other expedient of the same kind, can add any thing to the real working power of the machine. Mechanism is the means by which power is modified and conveyed to the working points, not the agent by which it is produced. The real and the only source of power in the steam engine is to be found in the phenomena which are evolved in the conversion of water into vapour (for an account of which phenomena see STEAM); and therefore the limit of railway speed must always depend on the rate at which the locomotive boiler is capable of evaporating water. The experiments above explained show the actual evaporating powers possessed by the boilers now in use, and every addition to such evaporating power will produce a corresponding, though not a proportionate, augmentation of the speed of railway trains.

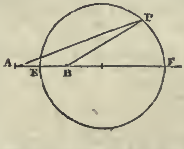
Nothing can be more absurdly exaggerated than the accounts which have been put in circulation of the speed attained on railways. No reliance whatever can or ought to be placed on such reports, unless they are attested by competent persons accustomed to that kind of inquiry, and who have been themselves witnesses of them. In the extensive courses of experiments which, for several years back, have been conducted by Dr. Lardner, he has never in any instance, even with an unloaded engine, exceeded a speed of 45 miles an hour; nor was that speed ever maintained for any considerable distance. With the best and most powerful engines on the Great Western Railway at their disposal, Mr. Nicholas Wood and Dr. Lardner were unable to attain a speed in their experiments exceeding 45 miles an hour. The question, however, of most interest to the public is, not the speed which can be obtained in experiments for short distances with engines put into racing order, but the average speed which can be maintained in the general working of a road. The returns of the railway companies, so far as they have been made public, do not supply the means of determining this; but it is known that the first class trains between London and Birmingham, a distance of 112 miles, cannot make the journey, under ordinary circumstances, in less than 5½ hours: this would give an average speed, including stoppages, of 20 miles an hour. On the Grand Junction line between Liverpool and Birmingham the journey, including stoppages, is usually made in 4⅘ hours, and the distance is 97 miles: this again is at the rate of about 20 miles an hour. No other lines of railway have yet been constructed of sufficient length to afford a fair estimate of average speed; and it may therefore be assumed that the present rate of railway travelling, for long distances with first class trains, stoppages included, is 20 miles an hour.

On the railway between Liverpool and Manchester the average speed of first class trains is greater. The railway is only 30 miles in length; and there is but one stoppage at Newton, which is so arranged as to be attended with very little loss of time. The journey is very frequently made in an hour, and seldom exceeds 80 minutes; the average speed for the fastest trains on that line is therefore probably not less than 25 miles an hour, including stoppages. (For further details respecting the locomotive engine, see *Lardner on the Steam Engine*, 7th edit. 1840.)

LOCOMOTIVE POWER, in contradistinction to stationary power, is any kind of moving power applied to the transport of loads on land which travels with the load which it draws. Horses employed to draw carriages or carry loads are locomotive powers. *See* LOCOMOTIVE ENGINE.

LO'CULICI'DAL. In Botany, a term applied to the dehiscence of a fruit when it takes place through the back of the cells. It is what botanists formerly called a dehiscence with the valves opposite the dissepiments.

LO'CUS (Lat. *place*), in the Geometrical Analysis, is the line traced by a point which varies its position according to some determinate law. For example, let this problem be proposed: To find a point P such that its distances from two given points, A and B, shall have a given ratio. If the line joining A and B be divided in E, so that A E is to E B in the given ratio, then a point is found which fulfils the conditions of the problem.



But this is not the only point which has this property; for let F be taken in the prolongation of A B, so that A F is to B F in the given ratio, and on E F as a diameter let a circle be described; then, if straight lines be drawn from A and B to any point whatever, P, in the circumference of this circle, A P will have to P B the same ratio as A E to E B, or as A F to F B, that is, the ratio given. The circle E P F is hence called the *locus* of the point P.

When the locus of the variable point is a straight line or a circle, it was called by the ancient geometers a *plane locus;* and when one of the conic sections, a *solid locus.*

The *plane loci* formed a branch of the ancient analysis, which, according to the account of Pappus, was treated of by Apollonius in two books which have been lost. They were partly restored by Schooten, a Dutch geometer, who flourished in the 17th century, and by Fermat; but afterwards in a complete manner by Dr. Simson of Glas-

gow, whose treatise, *De Locis Planis*, published in 1749, is a model of geometrical elegance. The principal propositions may be found in *Leslie's Geometrical Analysis*.

The moderns distinguish the loci into orders, according to the dimensions of the algebraic equations by which they are represented. Thus the equation $ax + by + c = o$ is a locus of the first order; $ax^2 + by^2 + cxy + dx + ey + f = o$, a locus of the second order, and so on. The loci of all equations of the second degree are conic sections or circles. (See *Maclaurin's Algebra*.)

LO'CUST. From the Latin word signifying a crayfish; but now the common name of a species of insects, forming a group or subgenus of the *Gryllus* of Linnæus. They have coloured elytra, and large wings, disposed when at rest in straight fan-like folds, as in other Orthoptera, and frequently exhibiting bright blue, green, or red colours. The thorax is capacious, to afford room for the powerful muscles of the wings, and is marked in many species with one or more crests or wart-like prominences. The locusts fly by starts, but frequently rise to a considerable height. Certain species, called "migratory locusts," unite in incalculable numbers, and emigrate, resembling in their passage through the air a dense cloud: wherever they alight all signs of vegetation quickly disappear, and cultivated grounds are left a desert. But the mischief does not end here; for when dead the mass of decomposing bodies is so great that the air becomes poisoned by the fetid exhalations. The 2d chapter of Joel gives a powerful description of the devastation committed by these destructive insects.

M. Miot, in his translation of Herodotus, has given it as his opinion that the heaps of bodies of winged serpents which that historian states that he saw in Egypt were nothing more than masses of this species of locust. These insects are eaten in various parts of Africa, where the inhabitants collect them both for home consumption and for commerce. They take away their elytra and wings, and preserve them in brine. One species (*Acridium migratorium*, Latr.) occasionally commits devastations in the south of Europe and Poland; and stragglers have occasionally reached our own coasts. In the United States the term "locust" is applied to a species of *Cicada*, which by their numbers and voracity are almost as destructive as the true locusts of the old world.

LOCU'STA. In Botany. If that form of inflorescence called a spike consist of flowers destitute of calyx and corolla, the place of which is occupied by bracteæ, the rachis is flexuose and toothed, and does not fall to the ground with the flowers, as happens in grasses, each part of the inflorescence so arranged is called a *locusta*, the structure of which is as follows:—At the base are two opposite empty bracteæ called glumes, one of which is attached to the rachis a little above the base of the other; above the glumes are several florets sitting in denticulations of the rachis; each of these consists of one bractea, sometimes with the midrib quitting the lamina a little below the apex, and elongated into a bristle; and of another bractea, facing the first, with its back to the rachis, bifid at the apex, with no dorsal vein, but with its edges inflexed, and a rib on each side at the line of inflexion; and, lastly, within these bracteæ are situated two extremely minute fleshy scales, which are sometimes connate, and stand at the base of the sexual organs.

LODE. A term used by miners, generally synonymously with metallic or mineral *vein*. The lodes containing metallic ores are said to be *alive*; others which merely contain lapideous matters are called *dead lodes*.

LODGE. (Fr. logis.) In Architecture, a small house situated in a park or domain, subordinate to the mansion; also, the cottage situated at the gate of the avenue that leads to the mansion.

LODGE. *See* FREEMASONRY.

LODI'CULA. In Botany, a term given by Palisot de Beauvois to the two minute, colourless, fleshy, hypogynous scales which are situated beneath the ovary of grasses.

LOESS. A German geological term, applied to a tertiary alluvial deposit which occurs in patches between Cologne and Basle. The term is often used by English geologists in reference to that peculiar yellow loam with calcareous concretions.

LOG, LOG-LINE. In sea language, the log is a piece of wood, in the form of a sector of a circle (usually a quadrant) of five or six inches radius. It is about a quarter of an inch thick; and so balanced, by means of a plate of lead nailed to the circular part, as to swim perpendicularly in the water, with about two thirds immersed under the surface. The log-line is a small cord, one end of which is fastened to the log, while the other is wound round a reel in the gallery of the ship. The log thus poised keeps its place in the water, while the line is unwound from the reel as the ship moves through the water; and the length of line unwound in a given time gives the rate of the ship's sailing. This is calculated by *knots* made on the line at certain distances, while the time is measured by a sand-glass of a certain number of seconds. In order to avoid calculation, the length between the knots is so proportioned to the time of the glass that the number of knots unwound while the glass runs down shows the number of miles the ship is sailing per hour. Thus, suppose the glass to be a half-minute one, it will run down 120 times in an hour. Now, distances by sea are reckoned by nautical miles of 60 to a degree; so that each mile contains about 6100 feet, the 120th part of which is 51 feet. If, therefore, the knots (which are pieces of coloured cloth) are fastened to the log-line at distances of 51 feet, the number of knots unwound from the reel in half a minute is the number of miles the ship runs in one hour. If the glass runs down in less than half a minute, the intervals between the knots must be diminished in proportion. The first knot is placed about five fathoms from the log, to allow the latter to get clear of the ship before the reckoning commences; and the part of the line between the lead and the first knot is called the *stray-line*.

LO'GAN STONES. *See* ROCKING STONES.

LO'GARITHM. (Gr. λογος, in the sense of *a proportion*, and αριθμος, *number*.) The logarithm of a number is the exponent of the power to which another given invariable number must be raised in order to produce the first number. Thus, in the common system of logarithms, in which the invariable number is 10, the logarithm of 1000 is 3, because 10 raised to the third power is 1000. In general, if $a^x = y$, in which equation a is a given invariable number, then x is the logarithm of y. All absolute numbers, whether positive or negative, whole or fractional, may be produced by raising an invariable number to suitable powers. The invariable number is called the *base* of the system of logarithms: it may be any number whatever, greater or less than unity; but, having been once chosen, it must remain the same for the formation of all numbers in the same system. Whatever number may be selected for the base, the logarithm of the base is 1, and the logarithm of 1 is 0. In fact, if in the equation $a^x = y$ we make $x = 1$, we shall have $a^1 = a$, whence, by the definition, log. $a = 1$; and if we make $x = 0$, we shall have $a^0 = 1$, whence log. $1 = 0$.

From the nature of the exponential equation, by which logarithms have been defined, it is easy to discover some of the principal properties and uses of those artificial numbers. Suppose that we have a series of numbers, y, y', y'', y''', &c., to be multiplied together. Let a be the base of the system of logarithms (supposed to be calculated), and let x, x', x'', x''', &c. be the logarithms of y, y', y'', y''', &c. respectively. We have then, according to the definition, the series of equations

$$y = a^x,\ y' = a^{x'},\ y'' = a^{x''},\ y''' = a^{x'''},\ \&c.$$

Multiplying the corresponding members of these equations into each other, we get

$$y\,y'\,y''\,y'''\ \&c. = a^{x + x' + x'' + x''' + \&c.};$$

whence log. $y\,y'\,y''\,y'''$ &c. $= x + x' + x'' + x''' +$ &c. $=$ log. $y +$ log. $y' +$ log. $y'' +$ log. $y''' +$ &c.: whence we infer this chief property of logarithms, namely, that the logarithm of a product is equal to the sum of the logarithms of its factors.

Again, let there be two numbers, y and y', to be divided the one by the other, and let x and x' be their logarithms. We have, as before, the equations $y = a^x$, and $y' = a^{x'}$; whence $\frac{y'}{y} = a^{x' - x}$, and therefore log. $\frac{y'}{y} = x' - x =$ log. $y' -$ log. y; that is to say, the logarithm of the quotient of a division is equal to the difference between the logarithm of the dividend and the logarithm of the divisor.

These properties of logarithms are of very great importance in facilitating the arithmetical operations of multiplication and division. For if a multiplication is to be effected, it is only necessary to take from the logarithmic tables the logarithms of the factors, and add them into one sum, which gives the logarithm of the required product; and on finding in the table the number corresponding to this new logarithm, the product itself is obtained. Thus by means of a table of logarithms the operation of multiplication is performed by simple addition. In like manner, if one number is to be divided by another, it is only necessary to subtract the logarithm of the divisor from that of the dividend, and to find in the table the number corresponding to this difference, which number is the quotient required. Thus, the quotient of a division is obtained by simple subtraction.

Logarithms apply with equal advantage to the formation of powers and extraction of roots. Let y be a number to be raised to the power m (m being any number, whole or fractional, positive or negative). As before, we have $y = a^x$; and, on raising both sides of the equation to the power m, $y^m = a^{mx}$: whence, by the definition, log. $y^m = m\,x = m$ log. y; that is, the logarithm of the power of a number is equal to the product of the logarithm of the number by the exponent of the power.

If in the equation log. $y^m = m$ log. y we make $m = \frac{1}{n}$, we shall have log. $y^{\frac{1}{n}}$ (or log. $\sqrt[n]{y}$) $= \frac{1}{n}$ log. y; that is to say,

the logarithm of any root of a number is equal to the logarithm of the number divided by the index of the root.

From these two last results it is obvious that by means of a table of logarithms numbers may be raised to any power by simple multiplication, and that the roots of numbers may be extracted by simple division.

The properties which have now been demonstrated are true of every system of logarithms which may be adopted; but their application to numerical computations supposes the construction of a table, including on the one hand the natural numbers, and on the other the logarithms of those numbers calculated for a given base. The tables usually employed are those of which the base is 10, and their construction is equivalent to the solution of the algebraic equation $10^x = y$. Hence, making y successively equal to the numbers 1, 2, 3, 4, &c., we have to resolve the equations

$$10^x = 1,\ 10^x = 2,\ 10^x = 3,\ 10^x = 4, \text{ \&c.}$$

The labour of computing the tables is greatly abridged by the circumstance that it is only necessary to calculate the logarithms of the prime numbers; for, as all the other numbers may be obtained by the multiplication of prime numbers into each other, their logarithms, according to what has been already shown, may be found by the addition and subtraction of the logarithms of the prime numbers. Hence a table containing merely the logarithms of the prime numbers is all that is strictly necessary for effecting computations by logarithms.

When a table of logarithms has been calculated for any given base, it is easy to find by means of it any other system of logarithms corresponding to a different base, without having again recourse to the solution of exponential equations. Thus, supposing a system of logarithms has been calculated of which the base is a, or, which is the same thing, that the value of x has been found for every different value of y in the equation $a^x = y$, and that it is required to construct another table of which the base is b, or to find the values of v corresponding to every different value of y in the equation $b^v = y$, we may proceed as follows:—Taking the logarithms of both members of this last equation from the table supposed already calculated, of which the base is a, and recollecting that $\log. b^v = v \log. b$, we have $v \log. b = \log. y$; whence $v = \frac{\log. y}{\log. b}$. But because $b^v = y$, it follows that v is the logarithm of y in the system of which the base is b; therefore, denoting the logarithms in this new system by L, we have $L\,y = \frac{\log. y}{\log. b}$. Hence it appears that, in order to find the logarithm of any given number y in the new system, it is only necessary to multiply its logarithm in the system already calculated by the constant number $\frac{1}{\log. b}$. This constant number, by means of which we pass from the one table to the other, is called the *modulus* of the new table with reference to the old.

In the common system of logarithms of which the base is 10, those numbers only which are perfect powers of 10 (that is, 100, 1000, &c.) can have commensurable logarithms. The logarithms of all other numbers are incommensurable, and can only be obtained to a certain degree of approximation. In general, the approximation will be sufficient if carried to the seventh decimal figure, and accordingly the ordinary tables contain the logarithms only to seven places of decimals; but where very great accuracy is required, as in some astronomical calculations, it may be necessary to use logarithms exact to ten places. In Vlacq's tables they are computed to this extent.

The relation between a number and its logarithm in the common system being $10^x = y$ (where y is the natural number and x its logarithm), if we make successively

$$x = 0, 1, 2, 3, 4 \ldots . n,$$

we shall have for the corresponding values of y

$$y = 1, 10, 100, 1000, 10000 \ldots . 10^n;$$

and if we make

$$x = 0 - 1 - 2 - 3 - 4 \ldots . - n,$$

we shall have

$$y = 1, \frac{1}{10}, \frac{1}{100}, \frac{1}{1000}, \frac{1}{10000} \ldots \frac{1}{10^n}.$$

From these series it is evident that the logarithms of all numbers greater than unity are positive, and that the logarithms of all fractions are negative. It is also evident that the logarithm of every number between 0 and 10 is a decimal, of every number between 10 and 100 is 1 + a decimal, of every number between 100 and 1000 is 2 + a decimal, and so on. But the digits in any number between 10 and 100 are 2, between 100 and 1000 are 3, and so on; therefore the common logarithm of any number is expressed by the number of its digits diminished by unity, with a certain decimal fraction added. For example, the number 73594, comprised between 10000 and 100000, or between 10^4 and 10^5, has for its logarithm 4, with a decimal added. This integral part of the logarithm, which is common to all numbers beween two successive powers of 10, is called the *characteristic*, because it shows at once of how many digits the natural number corresponding to the logarithm to which it is prefixed is composed. If, then, we know the logarithm of any number, we have only to add 1, 2, 3, &c. to its characteristic, in order to have the logarithm of a number 10 times, 100 times, or 1000 times, &c. as great. Thus we have

$$\begin{aligned} \log.\ 73594 &= 4{\cdot}8668424 \\ \log.\ 7359{\cdot}4 &= 3{\cdot}8668424 \\ \log.\ 73{\cdot}594 &= 1{\cdot}8668424 \\ \log.\ 7{\cdot}3594 &= 0{\cdot}8668424 \\ \log.\ {\cdot}73594 &= \bar{1}{\cdot}8668424 \end{aligned}$$

In this last example the negative sign is placed over the characteristic, this only being negative. But it is more usual and convenient to substitute for the negative characteristics their arithmetical complements; thus,

$$\begin{aligned} \log.\ {\cdot}73594 &= 9{\cdot}8668424 \\ \log.\ {\cdot}073594 &= 8{\cdot}8668424 \\ \log.\ {\cdot}0073594 &= 7{\cdot}8668424 \end{aligned}$$

Regard must be had to this substitution in the final result; but no mistake is likely to arise, for its effect would be to carry the decimal point 10 digits to the right or left of its true place—an error which would at once be evident. In modern tables the characteristic is properly omitted; the logarithm to which it would be prefixed belonging, in fact, not only to one particular number, but also to all multiples or sub-multiples of that number by 10.

The methods employed by the first computers of the logarithmic tables were founded on the successive extraction of roots, and involved calculations of very great labour; but analysts have since discovered series by which the computations are rendered much more expeditious and easy. Let it be required to find the logarithm of any number x by means of a converging series. Assume

$$\log. (1 + x) = A\,x + B\,x^2 + C\,x^3 + D\,x^4 + \text{\&c.} \ldots (1)$$

in which A, B, C, D, &c. are coefficients to be determined. Taking another number z, we shall have, in like manner,

$$\log. (1 + z) = A\,z + B\,z^2 + C\,z^3 + D\,z^4 + \text{\&c.} \ldots (2)$$

Subtracting equation (2) from (1) we get

$$\log. (1 + x) - \log. (1 + z) = A\,(x - z) + B\,(x^2 - z^2) + C\,(x^3 - z^3) + \text{\&c.} \ldots (3).$$

But, by the nature of logarithms, $\log. (1 + x) - \log. (1 + z) = \log. \frac{1 + x}{1 + z} = \log. \left(1 + \frac{x - z}{1 + z}\right)$; and, on developing this expression in the same manner as $\log. (1 + x)$ in the equation (1), we have

$$\log. \left(1 + \frac{x - z}{1 + z}\right) = A \frac{x - z}{1 + z} + B \left(\frac{x - z}{1 + z}\right)^2 + C \left(\frac{x - z}{1 + z}\right)^3 +, \text{\&c.}$$

Substituting this development for $\log. (1 + x) - \log. (1 + z)$, in the equation (3), and dividing both sides by $(x - z)$ there results

$$A \frac{1}{1 + z} + B \frac{x - z}{(1 + z)^2} + C \frac{(x - z)^2}{(1 + z)^3} +, \text{\&c.}$$
$$= A + B\,(x + z) + C\,(x^2 + x\,z + z^2) +, \text{\&c.}$$

Now, as this equation is true independently of any particular values of x and z, let us suppose $x = z$, and it becomes

$$A \frac{1}{1 + x} = A + 2\,B\,x + 3\,C\,x^2 + 4\,D\,x^3 + \text{\&c.},$$

which, on expanding the quantity $\frac{1}{1 + x}$ by division, gives $A\,(1 - x + x^2 - x^3 + x^4 -, \text{\&c.}) = A + 2\,B\,x + 3\,C\,x^2 + 4\,D\,x^3 +, \text{\&c.}$ Therefore, by the theory of indeterminate coefficients, we must have the separate equations $A = A$, $-A = 2\,B$, $+A = 3\,C$, $-A = 4\,D$, &c.; and on substituting the resulting values of B, C, D, &c., in terms of A in equation (1), we get

$$\log. (1 + x) = A\left(\frac{x}{1} - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \frac{x^5}{5} -, \text{\&c.}\right)$$

The quantity A, which is still indeterminate, is the modulus; and on assigning to it a particular value, we characterize the system which we wish to consider.

Let us suppose $A = 1$, and denote the particular system of logarithms resulting from this supposition by L; we shall then have

$$L\,(1 + x) = x - \tfrac{1}{2}\,x^2 + \tfrac{1}{3}\,x^3 - \tfrac{1}{4}\,x^4 +, \text{\&c.}$$

This series in its present form is unfit for the calculation of the logarithms of whole numbers, for when x is greater than unity it is divergent; but it may be easily transformed into others having the required properties. On substituting $-x$ for x, it becomes

$$L\,(1 - x) = -x - \tfrac{1}{2}\,x^2 - \tfrac{1}{3}\,x^3 - \tfrac{1}{4}\,x^4 -, \text{\&c.}$$

And on substracting this from the former series, we have,

since $L(1+x) - L(1-x) = L\left(\frac{1+x}{1-x}\right)$,

$$L\frac{1+x}{1-x} = 2\left(\frac{x}{1} + \frac{x^3}{3} + \frac{x^5}{5} + \frac{x^7}{7} +, \&c.\right).$$

Let us now suppose $\frac{1+x}{1-x} = 1 + \frac{1}{z}$, or $x = \frac{1}{2z+1}$;

then, since $L\left(1+\frac{1}{z}\right) = L\frac{z+1}{z} = L(z+1) - Lz$,

the last series becomes, by substitution, $L(z+1) - Lz$

$$= 2\left(\frac{1}{2z+1} + \frac{1}{3(2z+1)^3} + \frac{1}{5(2z+1)^5} +, \&c.\right)$$

This series gives the difference between the logarithms of two consecutive numbers, and it converges with sufficient rapidity. Supposing successively $z = 1, 2, 3, 4$, &c., it gives

$$L\,2 = 2\left(\frac{1}{3} + \frac{1}{3\cdot3^3} + \frac{1}{5\cdot3^5} + \frac{1}{7\cdot3^7} +, \&c.\right)$$

$$L\,3 - L\,2 = 2\left(\frac{1}{5} + \frac{1}{3\cdot5^3} + \frac{1}{5\cdot5^5} + \frac{1}{7\cdot5^7} +, \&c.\right)$$

$$L\,4 - L\,3 = 2\left(\frac{1}{7} + \frac{1}{3\cdot7^3} + \frac{1}{5\cdot7^5} + \frac{1}{7\cdot7^7} +, \&c.\right)$$

It will be observed that as the values of z increase the series becomes much more rapidly convergent. Suppose, for example, $z = 100$; we have then

$$L\,101 = L\,100 + 2\left(\frac{1}{201} + \frac{1}{3\cdot201^3} + \frac{1}{5\cdot201^5} +, \&c.\right)$$

The logarithm of 100 being supposed known, the first term of this series will give the logarithm of 101 true to seven places of decimals.

The series now found gives the logarithms of the particular system of which the modulus is 1, and which is called the *Napierian system*, because it is that according to which logarithms were first computed by their inventor, Baron Napier. But, as has already been shown, when the logarithms have been found in any one system, they may be transferred into those of any other system by means of a constant factor. In the common system the base is 10, and the Napierian logarithm of any number is consequently transformed into the common logarithm of the same number by multiplying by the modulus $\frac{1}{L\,10}$.

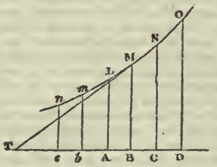
This number, which is of great importance in the computation of the logarithmic tables, is found to be 0·4342944819, &c., the Napierian logarithm of 10 being 2·30258509, &c. It may also be remarked that this modulus 0·4342944819 is the ordinary logarithm of the base of the Napierian system; for, calling e this base, we shall have $e^{L\,10} = 10$, whence, taking the ordinary logarithm of both sides of the equation, $L\,10 \times \log. e = \log. 10 = 1$; therefore $\log. e = \frac{1}{L\,10}$ $= 0{\cdot}4342944819$. On passing to numbers we find $e = 2{\cdot}7182818284$.

The Napierian logarithms are sometimes called the *natural logarithms*, on account of the modulus of the system being unity; and more frequently *hyperbolic logarithms*, because they represent the area of a rectangular hyperbola between its asymptotes.

Logarithms were invented by Lord Napier, Baron of Merchiston in Scotland; and made known in a work published by him in 1614, under the title *De mirifici Logarithmorum Canonis Constructione*. Henry Briggs, a contemporary of Napier, and professor of geometry in Gresham college, constructed another system, having for its base the number 10, which, corresponding with our system of numeration, is much more convenient for the ordinary purposes of calculation. Briggs calculated the logarithms to 14 places, besides the index, of all numbers between 1 and 20,000, and between 90,000 and 100,000, and published them in his *Arithmetica Logarithmica* in 1624. Adrian Vlacq, a native of Holland, computed the logarithms of the numbers from 20,000 to 90,000, and thus completed what had been begun and partly accomplished by Briggs; but he reduced the tables to 10 decimal places. Vlacq's *Arithmetica Logarithmica* was published at Gouda in 1628, and contained the logarithms of all numbers from 1 to 100,000, calculated to 10 decimals; as also the logarithms of the sines, tangents, and secants of every minute of the quadrant. Vlacq afterwards, in 1633, published another most valuable work, his *Trigonometria Artificialis*, containing the logarithmic sines, cosines, tangents, and cotangents for every ten seconds of the quadrant, calculated from the natural sines, &c. of the *Opus Palatinum* of Rheticus. In the same year another work of the same kind, the *Trigonometria Britannica*, was published at Gouda, containing the logarithmic sines and tangents for the 100th part of every degree of the quadrant, together with a table of natural sines, tangents, and secants. These had been computed by Briggs.

Logarithms being of constant use in astronomical and trigonometrical calculations, the tables which have been published are very numerous. The most complete are those of Vlacq, already mentioned, to ten decimals; but they are very scarce, and can with difficulty be procured. There is an edition of them by Vega, in 1797, also scarce. *Gardiner's Logarithms*, printed in 1742, in 4to., and another edition of them at Avignon in France in 1770, are to seven decimals. *Callet's Logarithms*, in 8vo., like Gardiner's, contain the logarithmic sines, &c. for every 10 seconds. *Taylor's Logarithms*, in 4to., and also *Baguay's*, have them to every second. *Hutton's Logarithms*, and *Babbage's Logarithms of Numbers*, are well known. The latter was carefully collated, and is very accurate and convenient. *Hulsse's Sämmlung Mathematischer Tafeln* (8vo. Leipsig, 1840) deserves to be mentioned as a very useful collection. The above (excepting Vlacq's and Vega's) are all to seven decimal figures; but for many purposes logarithms to a less number of decimals are sufficiently accurate. For navigation and surveying, tables to six figures are the most convenient, as they give in general the trigonometrical lines correct to single seconds. The best tables of this kind are *Farley's Tables of Six-figure Logarithms* (12mo. 1840). For many auxiliary computations in astronomy it is sufficient to have the logarithms to five places. The reprint of *Lalande's Five-figure Table* by the Useful Knowledge Society (18mo. 1839) is convenient, and may be relied on for accuracy.

LOGARITHMIC or LOGISTIC CURVE. In the higher Geometry, a curve line having this property, that its abscissa are proportional to the logarithms of the corresponding ordinates. It is contructed in the following manner:—On the straight line A D let the parts A B, A C, A D, &c. be taken in arithmetical progression (or such that A B = B C = C D = &c.), and from the several points A, B, C, D, &c. let the perpendiculars A L, B M, C N, D O, &c. be erected, forming a geometrical progression, or such that A L : B M = B M : C N = C N : D O = &c.; then their summits L, M, N, O, &c. will mark the logarithmic curve. The curve is ascending or descending, according as it is continued from L upwards towards M, or downwards towards m.

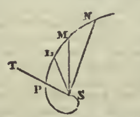


The equation of the curve is $x = a \log. y$; and hence its principal properties are easily deduced. Taking the differential of the equation, we get $dx = a\frac{dy}{y}$; whence $y\frac{dx}{dy} = a$. Now in any curve $y\frac{dx}{dy}$ is the expression of the subtangent: therefore the subtangents of the logarithmic at different points are all equal. The constant a to which the subtangents are equal is the modulus of the system of logarithms represented by the particular curve When the subtangent (B T for example) is equal to A L, the primary ordinate which represents unity, the curve will exhibit the natural or Napierian logarithms.

From the equation $dx = a\frac{dy}{y}$ we have $y\,dx = a\,dy$; but $y\,dx =$ the differential of the area, therefore the area $= \int a\,dy = ay +$ const. Making first $y =$ D O, and then $y =$ C N, we have the area C N O D $= a$ (D O $-$ C N); that is to say, the area contained between two ordinates is equal to the rectangle under their difference and the constant subtangent.

The logarithmic curve was proposed by Gregory of St. Vincent soon after the discovery of logarithms, and its leading properties were investigated by Huygens and others. Great use is made of it in various applications of physical science, and particularly in exhibiting the relations of elastic fluids. (See *Keill's Tract on Logarithms*; *Euler's Introd. in Anal. Inf.*, vol. ii.; *Leslie's Geometry of Curves*, &c.)

LOGARITHMIC SPIRAL, or LOGISTIC SPIRAL. A curve line, which is generated as follows:—Let the line S T revolve uniformly about a fixed point S, while another point P advances or recedes on S T with a velocity always proportional to its distance from the centre S; then the point P will trace out the logarithmic spiral.



From this definition of the curve it follows that radiants S L, S M, S N, &c., making equal angles with each other, are continued proportionals; and that the angles about the pole S are the logarithms of the ratios of the successive

radiants: whence the curve has its name. Let $SL = 1$, $SM = y$, the angle $LSM = z$; then $z = a \log. y$, where a is a constant quantity. The curve is consequently analogous to the common logarithmic, the difference being that the abscissa are in the latter taken as straight lines, whereas in the case of the spiral they may be conceived to be taken as the arcs of a circle.

The logarithmic spiral has many remarkable properties. One of them is, that the curve intersects all its radiants at the same angle; and this angle is the modulus of the system of logarithms which the particular spiral represents. Another of its properties is that its involute and evolute are the same curve with itself. Newton proved that if the force of gravitation had been inversely as the *cube* of the distance, instead of the *square*, the planets would have shot off from the sun in logarithmic spirals. (*Principia*, lib. i. prop. ix.)

LOGEI'ON. (Gr. λογεῖον.) In ancient Architecture, the Greek name for *proscenium* (which see). By the Romans it was called the *pulpitum*.

LO'GIC (Gr. λογίκη (τέχνη understood; from λόγος, *speech*, *discourse*, or *calculation*), has been defined the science, and also the art, of reasoning. It is a science, because it investigates those principles on which reasoning proceeds: it has been termed an art, as furnishing rules whereby the formal part of an argument may be constructed. Logic was highly valued, perhaps overvalued, among ancient philosophers. The Stoics, in particular, were celebrated for their application of its principles to their own favourite metaphysical discussions. From the abuse of logical knowledge arose the celebrated fallacies of the Sophists, who, according to the satirical representations of Athenian writers, were hired to furnish their pupils with the means of defending right or wrong positions with equal facility. Zeno of Elea is called the father of logic, or dialectics, according to the ancient appellation of the science: but we are not well acquainted with the discipline which he taught; although it can hardly have consisted, as more recent writers have represented, of a mere manual of captious fallacies. But it is to the master mind of Aristotle that the science owes, as far as we are able to ascertain, not only its first exposition, but its complete development; for although logic has been extensively interwoven in later times with the subtleties of metaphysics and of rhetoric, yet, as far as the limited province of the pure science extends, little has been done besides placing in a clearer light the discoveries of the Stagyrite. When, in the middle ages, the Aristotelian logic became the foundation of the scholastic philosophy (which was little better than a revival under another form of that of the Athenian sophists), attempts were made, especially one by the famous Raymond Lullius, to throw the science into a new form, but without success. In consequence of the various misapplications and perversions which the system had undergone in the hands of later dialecticians, it fell into great disrepute in modern times; and many of our first metaphysical writers, as Locke, for example, have treated it with very unmerited contempt. Confined to that narrow limit to which alone its rules really extend, it is a serviceable exercise for the mind, and affords an accurate insight into the formal part or machinery of reasoning.

However multifarious the subjects to which reasoning may be applied, and however complicated its details may become, the process by which all reasoning is conducted is one and the same. Whoever seeks to prove that because one thing is thus, therefore another thing is so, whether he be a philosopher pursuing a recondite truth, or a labourer commenting on the events of his daily life, cannot travel out of the bounds of the Aristotelian syllogism. In analysing the process in question, we find, in the first place, that every truth or apparent truth, arrived at by reasoning, technically termed a conclusion, is deduced from two other propositions, technically termed premises, either both expressed, or one expressed and the other implied. In many instances it is at once evident to the mind of one capable of reasoning that if the two premises be true, the conclusion must follow. Thus, if I wish to prove the mathematical truth, that every A is equal to B, I find a third quantity, C, which is equal to both; and my argument then assumes the following shape — whatever is equal to C is equal to B; but every A is equal to C, therefore every A is equal to B. Here the connection between the conclusion and the premises is at once evident and true; but there are many cases in which there is an apparent connection which is in reality false: in other words, from two premises a conclusion is deduced, which, admitting the truth of those premises, does not in reality follow from them. The following, for example, is an instance of a conclusion incorrectly deduced from its premises, which, nevertheless, might at first sight pass current for reasoning: "Every rational agent is accountable; brutes are not rational agents, therefore brutes are not accountable." To explain the reason why the first of these two arguments is sound, and the latter unsound, requires not the examination of truths in mathematics or in natural religion, but simply of the common process of reasoning; and it is the means of making such an analytical investigation which are afforded by logic.

The first of these arguments is a correct, the latter a false or apparent, syllogism (*see* SYLLOGISM); and the validity of the first, and invalidity of the latter, depend upon the necessary or unnecessary connection between the premises and the conclusion; the rules for ascertaining which will be found compendiously given under the head SYLLOGISM. A single sentence may often be found to contain, elliptically expressed, and compressed into a narrow compass, a whole chain of separate syllogisms; but every single conclusion has been arrived at by this process, and by this only.

The principle of the syllogism is contained in the famous maxim termed in the schools of the middle ages the "dictum de omni et nullo,"— viz. that "whatever is predicated (*i.e.* affirmed or denied) universally of any class of things, may be predicated, in like manner (*i.e.* affirmed or denied) of any thing comprehended in that class." Thus, for example, in the instance previously given of a valid argument, if it can be predicated of the whole class of things which are equal to C that they are also equal to B; if I find any thing equal to C, I may predicate of it that it is equal to B also. Hence my second premise, A is equal to C, serves to bring me, logically, to the required conclusion — that A is equal to B. This, therefore, is the general principle on which that process is conducted which takes place in every syllogism.

In order that reasoning may be contemplated simply as reasoning, without any reference to the essential truth or falsehood of the propositions contained in it, which have nothing to do with the science we are now considering, and also with a view of furnishing brief and expressive forms, like those of algebra, instead of words at length, a set of arbitrary symbols are employed in logic, to denote the quantity and quality, as they are termed, of propositions. Every proposition either affirms or denies a fact; every proposition also predicates (*i.e.* affirms or denies) that a certain attribute belongs either to a whole class, or to some members of a class, of objects: propositions are therefore, in quality, either affirmative or negative; in quantity, universal or particular. Thus the four symbols of propositions in logical manuals are, A, universal affirmative; I, particular affirmative; E, universal negative; O, particular negative. And the form of a syllogism, according to the character of each of its premises and of the conclusion, is expressed by three of these letters. Thus the syllogism first given, consisting of three universal affirmatives (for it will be found, on examination, that each proposition predicates a certain attribute of all the members of a class), will be designated by A A A; a syllogism termed in logical language *barbara*. *See* SYLLOGISM.

It is also found, on farther analysis, that a syllogism embraces three separate objects or notions, two of which are compared with the third, and, in consequence of that comparison, pronounced to agree or disagree with each other. Thus, in the syllogism "No dishonest man is a good citizen: Caius is a dishonest man; therefore Caius is not a good citizen." The individual object, "Caius," and the class of objects, "good citizens," being compared with a third class, "dishonest men," are found, the one to agree, the other to disagree, with that class; and hence it inevitably follows that they disagree with each other, — *i.e.* the conclusion of the syllogism is negative. These three objects or terms, as they are called in logic, occur in every syllogism. The predicate of the conclusion,—*i.e.* that term which, in the conclusion, is predicated of the other, in this instance "good citizen"— is called the major term; the subject of the conclusion—*i.e.* that term of which the other is predicated (Caius)—is the minor term; and the term with which the other two are respectively compared, "dishonest man," is the middle term.

But every word, or combination of words, is not capable of constituting a term — *i.e.* something which may be predicated of another thing, or of which another thing may be predicated. In the first place, adverbs, prepositions, nouns in any inflection from the nominative case, &c., can only form parts of a term; in logical phrase, they are syncategorematic: adjectives, also, have always, impliedly, a nominative subjoined, when employed as terms. Verbs are mixed words, being resolvable into a term employed as a predicate, united to the *copula* or auxiliary verb (*is* or *is not*). Thus, nouns in the nominative case alone are simple terms or categorematics; these, again, are either the name of an individual or the name of the class: the former (singular terms) may be subjects, but cannot be predicates; the latter may be either. Thus, in the proposition "Crassus is rich," the singular term, "Crassus," is the subject of which it is predicated that he is rich — *i.e.* a rich man.

A common term, being a word equally applicable to a number of individuals, expresses a notion formed by the faculty of abstraction. When, for example, we contem-

plate several individual oak trees, and abstract from each its separate peculiarities of height, growth, &c., we form the notion of an oak. Contemplating a number of trees of mixed species, and abstracting from each its specific peculiarities of leaf, fruit, &c., we next arrive at the common notion tree. These common notions or terms are then the *predicables* which can be affirmed or denied of other objects.

Predicables are divided into several kinds, although the division is, perhaps, strictly, rather appertaining to metaphysical than logical science. Every predicable is said, according to this division, to express either the genus, species, difference, property, or accident, belonging to an individual. (See these heads, and PREDICABLE.) But it is to be remembered that a predicable may be referred to one or other of these several kinds, according to the point of view from which it is contemplated. If I say of Cæsar that he is a "man," I express his species, considering him in those respects in which he differs from other animals. If I say that he was "brave," I express a property. If I predicate of him the several circumstances in which he absolutely differed from all other men, I express that property or that bundle of united properties which forms his "difference." Every predicable, with a little attention, may be ranged under one or the other of these five classes, although it must be confessed that the distinction seems occasionally arbitrary and unphilosophical.

In this hasty outline of some leading features of the art of logic, as taught at Oxford (where alone, we believe, pure unapplied logic forms a branch of study), we have chiefly made use of the Archbishop of Dublin Dr. Whately's valuable *Elements of Logic*.

The following passage is cited by Mr. Hallam from the *Port Royal Logic*, as giving a juster view of the value of the Aristotelian method than its admirers are wont to entertain:—"Cette partie, que nous avons maintenant à traiter, qui comprend les règles du raisonnement, est estimée la plus importante de la logique, et c'est presque l'unique qu'on y traite avec quelque soin; mais il y a sujet de douter si elle est aussi utile qu'on se l'imagine. La plupart des erreurs des hommes viennent bien plus de ce qu'ils raisonnent sur de faux principes, que de ce qu'ils raisonnent mal suivant leurs principes. Il arrive rarement qu'on se laisse tromper par des raisonnemens qui ne soient faux, que parceque la conséquence en est mal tirée; et ceux qui ne seraient pas capables d'en reconnaitre la fausseté par la seule lumière de la raison, ne le seraient pas ordinairement d'entendre les règles que l'on en donne, et encore moins de les appliquer. Néanmoins, quand on ne considéreroit ces règles que comme vérités spéculatives, elles serviraient toujours à exerçer l'esprit." (*Esprit de Penser*, part 3.) "To represent this portion of logical science as the whole," adds the same writer, "appears to me almost like teaching the scholar Euclid's axioms, and calling this the science of geometry." (*Introduction to the Literature of Europe*, vol. iii. p. 221.) All that can be said in answer is, that the more general meaning of the term logic is undefined, and that it is employed by various writers and schools in the most arbitrary manner; while this portion, though it may be but a small one, is so clearly marked out, and forms so distinct a body, that it has occupied in common language the character of the whole science.

LOGO′GRAPHY. (Gr. λογος, *speech*; γραφω, *I write*.) A system of taking down the words of an orator without having recourse to short-hand, which was put in practice during the French revolution. Twelve or fourteen reporters were seated round a table. Each had a long slip of paper, numbered. The writer of No. 1. took down the first three or four words, and as soon as they were spoken gave notice to his neighbour by touching his elbow, or some other sign; No. 2. passed the sign to No. 3., and so on, until the first line of each slip was filled; No. 1. then began the second line: thus all the 12 or 14 slips, when filled, being arranged parallel to each other, formed a single page. This mode required great attention and quickness, and was not found to answer well in practice. It was introduced in the National Assembly in October, 1790, the expenses being paid by the civil list; and continued until the 10th August, 1792, when Louis XVI. and his family, taking refuge from insurrection in the assembly, occupied the box of the logographe. After that time it was not used. (*Dictionnaire de la Conversation*.)

Logography is also used to denote a method of printing in which whole words in type are used instead of single letters. This method was at one time introduced into the printing of *The Times* newspaper; but after a short trial was abandoned as inconvenient.

LO′GOGRYPH. (Gr. λογος, and γριφος, *a net*.) A species of riddle proposed for solution, in order to exercise the mind, is so called. The word is used by Ben Jonson.

LO′GWOOD. The wood of the *Hæmatoxylon campechianum*, a tree growing in many parts of the West Indies and on the adjoining continent. It is employed in dyeing and calico-printing for the production of reds, blacks, drabs, and several compound colours. Its colouring principle has been termed *hæmatine*. An extract of logwood is used in medicine as an astringent. The price of logwood varies from 5*l*. 10*s*. to 7*l*. per ton; and the quantity imported into Great Britain in the three years ending 1839 averaged 15,000 tons.

LOI′MIC. (Gr. λοιμος, *contagious matter*.) Relating to the plague or contagious disorders.

LOK. In Northern Mythology, the name of a malevolent deity; corresponding to the Ahriman of the Persians, who is represented to be at war with both gods and men, and originating all the evil with which the universe is desolated. In the *Edda* (the great poem of the Norwegian nations) he is described as the great serpent which encircles the earth (supposed to be emblematical of sin or corruption), and as having given birth to Hela, or Death, the queen of the infernal regions.

LO′LLARDS. A class of persons in Germany and the Netherlands who professed, in the 14th century, to undertake spiritual offices in behalf of the sick and dead, and succeeded in attracting the attention and love of the mass of the people when they were in a great measure alienated from the secular and regular clergy by their general indifference and neglect. The origin of the name has been much disputed; but the inquiries of Mosheim seem to lead to the result that it is compounded of the German words *lallen* (identical with the *lallare* of the Romans and the *lull* of our own language, signifying to sing in a murmuring strain) and *hard*, a common affix, as in the somewhat similar word *beghard*. A Lollard, therefore, meant one in the habit of singing to the praise of God, or funeral dirges and the like, as was the custom of the early professors of this holy manner of life. The Lollards, however, were accused—probably through the envy and spite of the mendicant friars and others whose neglected duties they so zealously performed—of holding many heretical opinions. It is not impossible that there might have been some degree of enthusiasm mixed up with so ardent and unworldly a devotion; but the charges of violent reforming views, still more those of practical vice, appear to rest upon no authentic grounds. In process of time the term was applied by the partizans of the church to the heretics and schismatics of the day generally; and the followers of Wicliffe in England are frequently stigmatized under the name of Lollards. (See *Gieseler's Text-book*, transl., vol. iii. pp. 99. 128.)

LO′MBARD. A term anciently used in England for a banker or money-lender. The name is derived from the Italian merchants, the great usurers or money-lenders of the middle ages, principally from the cities of Lombardy, who are said to have settled in London in the middle of the 13th century, and to have taken up their residence in a street in the city which still bears their name. Stowe, in his *Survey of London*, says, "Then have ye Lombarde Street, so called of the Longobards and other merchants, strangers of diverse nations, assembling there twice every day. The meeting of which merchants there continued until the 22d of December, in the year 1568; on the which day the said merchants to make their meetings at the Bursse, a place then new builded for that purpose, in the ward of Cornhill, and was since, by her majesty Queen Elizabeth, named the Royal Exchange." (P. 202.)

LOME′NTUM. A fruit similar to a legume, excepting that it is contracted in the spaces between each seed, and there separates into distinct pieces; or is indehiscent, but divided by internal spurious dissepiments, whence it appears at maturity to consist of many articulations and divisions. It occurs in the genera *Ornithopus*, *Hedysarum*, &c.

LONG. A musical character of this form ꟼ, whose length in common time is equal to four semibreves, and consequently eight minims.

LO′NGICORNS, *Longicornes*. (Lat. longus, *long*; cornu, *a horn*.) The fourth tribe of Coleopterous insects in the system of Latreille; so called on account of the length of the antennæ, which are rarely shorter than the body, and commonly surpass it in length. But this conspicuous character is not the only one which the Longicorn beetles possess in common. In all of them the under part of the three first joints of the tarsi is furnished with a brush; the second and third are cordiform; the fourth is deeply bilobate; and there is a little nodule, resembling a joint, at the base of the last. The *ligula*, placed on a short and transversal *mentum*, is usually membranous, cordiform, emarginate, or bifid; but sometimes is corneous, and forms the segment of a very short and transverse circle. The antennæ are either filiform or setaceous: they are sometimes simple in both sexes, and sometimes serrate, pectinate, or flabelliform in the males. The eyes in some species are rounded and entire, or but slightly emarginate, and in these species the thorax is trapezoidal or narrowed anteriorly; but in most of the Longicorns the eyes are reniform and surround the base of the antennæ.

As the larvæ of a very great proportion of the Longicorns live in the interior of trees, or under their bark, they are destitute of feet, or have but very small ones.

Their body is soft, whitish, thickest anteriorly; and the head squamous, and provided with stout mandibles. They do much injury to trees, the large ones particularly, perforating them very deeply, and sometimes drilling them in every direction. Some of them attack the roots of plants.

The abdomen of the female Longicorns is terminated by a tubular and horny ovipositor. These insects produce a small sharp sound, by rubbing the pedicle of the base of their abdomen against the interior of the parietes of the thorax.

LO′NGIPALPS, *Longipalpi.* (Lat. longus, *long;* palpus, *feeler.*) The name of a family of Brachelytrous Coleopterans, or short-winged beetles, which have the maxillary feelers almost as long as the head.

LON′GIPE′NNATES, *Longipennes.* (Lat. longus, and penna, *a wing.*) A family of swimming birds, comprehending those in which the wings reach as far as or beyond the tail; as the tropic bird, albatross, &c. They are all denizens of the high seas, and from their powers of flight are to be met with in various latitudes. The hind toe is free or wanting. The beak is hooked or pointed at the tip.

LONGIRO′STERS, *Longirostres.* (Lat. longus, and rostrum, *a beak.*) The name of a tribe of Grallæ, or wading birds, including those in which the beak is remarkable for its length and tenuity, and by the high sensibility of its tip is well adapted for searching or probing in mud or sand for worms or insects. The different gradations in the form of the bill serve to divide the Longirosters into families and genera.

LONGI′SSIMUS DORSI. A muscle of the back, which assists others in keeping the spinal column erect.

LO′NGITUDE, in Astronomy, has two different significations, according as it is applied to a celestial or terrestrial object. The longitude of a heavenly body is the arc of the *ecliptic* intercepted between the vernal equinox and a great circle perpendicular to the ecliptic passing through the body. It is reckoned eastward all round the sphere, from 0 to 360°. The longitude and latitude of a celestial object, having reference to the ecliptic, and not to the plane of the earth's diurnal motion, cannot be directly observed. The elements necessary for determining a star's place, which are given directly by observation, are its right ascension and declination, from which the longitude and latitude must be calculated by the rules of spherical trigonometry. In the planetary theory, however, it is convenient to refer the motion of a planet to the plane of the earth's orbit, or to make the longitude and latitude the co-ordinates of its motion. But the places of the stars are always defined, by modern astronomers, by means of their right ascensions and declinations.

The longitude of a place on the earth is the arc of the *equator* intercepted between the meridian of the place and some conventional fixed meridian, which is regarded as the origin from which the measures are reckoned. Terrestrial longitudes and latitudes correspond to right ascensions and declinations in the heavens: with this distinction, however, that the right ascensions are always reckoned from the vernal equinox, or point in which the equator intersects the ecliptic; whereas the longitudes are reckoned by different geographers from different points, selected for some local reason, there being nothing connected with the earth's diurnal rotation which can render one point of the equator more convenient than another. Right ascensions are also reckoned in the same direction (eastward) round the complete circumference; while geographical longitudes are reckoned both eastward and westward, 180° each way.

The parallels of latitude on the earth are distinctly marked out by the diurnal circles described by the stars, and consequently latitude can always be determined by direct observation of the heavens: but the case is entirely different with respect to longitude; for to observers situated under the same parallel of latitude, but under different meridians, the heavens present exactly the same aspect, and there is nothing whatever to indicate any difference of locality. Longitude, therefore, cannot be measured by direct observation; it can only be inferred from the measurement of intervals of time to which it is proportional. In the course of a sidereal day the rotation of the earth brings successively every different meridian under the same star; and, the rotation of the earth being perfectly uniform, it follows that the angular distance of any two meridians will be the same part of 360° that the interval of time which elapses between their coming to the same star is of twenty-four hours. For example, if a star pass the meridian of a place A at a certain moment, and that of B exactly one hour of sidereal time later; then the difference of longitude between A and B is the twenty-fourth part of 360°, or 15°, and the longitude of B is 15° west of A. The determination of longitudes consequently resolves itself into the measurement of time; and as the time, or the instant of mean noon, at any place can always be found without difficulty, if an observer at one place can by any means determine the precise hour it is at any oth place *at the same instant*, he has then determined t difference of longitude between the two places.

Of the various methods by which differences of lo gitude may be determined, the simplest and most obvio is that of transferring chronometers from one place another. Suppose two observers, at the distant station A and B, each to regulate his clock according to the tr sidereal time of his station; and suppose a chronomete also regulated to true sidereal time, to be compared wi the clock at A, and then transported, without sufferi any change of rate, to B—the difference of the two cloc would thus be exhibited; and this difference is exact the time occupied by the equinoctial point, or by any st in passing from the meridian of A to that of B; or it is t difference of longitude of the two places expressed in sid real hours, minutes, and seconds. Were chronomete perfect, nothing more complete and convenient could b desired; but this unfortunately is even now very far fro being the case, and until within a comparatively ver recent time the practical determination of the longitud by means of chronometers could not be attempted.

Another method of determining the difference of lo gitude between two places, independently of astron mical observations, is that by telegraphic signals. Th method, though, from its nature, of limited application, susceptible of great accuracy. The explosion of a rocke the flash of gunpowder in an open dish, the extinctio of a bright light, &c., are instantaneous phenomen which can be seen at great distances and noted with th utmost precision. A signal of this kind, made at a sta tion visible from two observatories, must be seen at th same absolute instant of time from both; and the tim marked by the clock of each observatory at this instan being noted, the difference of their local times, and con sequently the difference of their longitudes, become known. This method is chiefly practised in connectio with geodetical operations for measuring degrees of lon gitude on the earth's surface, and is perhaps the bes that can be adopted for determining the difference o longitude between two observatories situated at no ver great distance from each other. By means of inter mediate signals, and observers suitably disposed betwee each, it may also be applied to transfer the time fron one place to another, when the distance is too great t allow an artificial signal of any kind to be seen fron both. (See *Phil. Trans.*, 1826.)

When the distance between two places is very consi derable, artificial signals cannot be employed, and i becomes necessary to have recourse to the methods fur nished by astronomy. These are principally the follow ing:—

1. *Eclipses of the Moon.*—The instant of time at whic the moon's disk enters or quits the earth's shadow i independent of the position of the observer; and there fore, if the phenomenon could be accurately observed would give the longitudes of all places from which th eclipse is visible. But the penumbra of the earth ren ders it impossible to determine the precise instant a which the disk enters into the true shadow: the ob servation, in fact, is uncertain to the amount of a minut of time, which corresponds to a quarter of a degree of lon gitude; and therefore this method, which was propose and employed by Ptolemy, is now altogether abandoned

2. *Eclipses of Jupiter's Satellites.*—These phenomen also occur at the same instant of absolute time to al places on the earth; but they are not susceptible of bein observed with much exactness, for the same reaso which renders the lunar eclipses uncertain, namely, th penumbra of the planet. The uncertainty is least i the case of the first satellite, on account of its quic motion; and as the eclipses of this satellite occur muc more frequently than those of the others, the observa tions are chiefly confined to it. The times of the eclipse of the three first satellites are given in the *Nautica Almanac;* so that an observer at any part of the world who observes one of these eclipses, has only to compar his local time with that assigned to the phenomenon i the almanac in order to determine the distance of hi meridian from that of Greenwich. But, on account o the uncertainty of the observation, the longitude obtaine by this method may be considerably in error.

3. *Occultations of Fixed Stars by the Moon.*—This method, which is one of the readiest and most useful on land, though it can seldom be practised at sea, consists in observing accurately the time at which a certain fixed star disappears behind the disk of the moon, or reappears after having been occulted. The first of these phenomena is called the immersion of the star, the second the emersion. But, on account of the moon's parallax, the immersion or emersion of a star behind her disk does not take place at the same absolute instant to observers on different parts of the earth; a calculation is therefore necessary to clear the observation of parallax, or to determine the time at which the phenomenon would have occurred if it had been seen from the centre of the earth. This reduction being made, the moon's apparent

semidiameter at that instant must be calculated; by means of which, after applying the proper corrections for parallax, refraction, &c., the exact distance of the star from the moon's centre at the moment of the immersion becomes known. Now, suppose the same occultation to have been observed at another place, and the true distance of the star from the centre of the moon computed in the same manner; or, without a corresponding observation, suppose the time at the second place (Greenwich, for example) to be computed, for which the star's distance from the moon was the same as observed at the first place, the comparison of those times will show the difference of the longitudes of the places. The length of the calculations by which the longitude is deduced is a disadvantage which attaches to this method. *See* OCCULTATION.

4. *Eclipses of the Sun.*—The longitude is deduced from the observation of solar eclipses, in the same manner, and by precisely the same sort of calculations, as from the occultation of fixed stars. An eclipse of the sun is, in fact, an occultation; but these phenomena occur so seldom at any particular place that they afford little assistance in the determination of longitudes. It may be remarked that the irregularities of the border of the moon's disk render the instant of the commencement or end of a solar eclipse, as also of the immersion or emersion of a fixed star, somewhat uncertain. But this uncertainty is corrected, or rather avoided, by measuring with a micrometer the distance between the two cusps, which, shortly after the commencement of the eclipse, appear as brilliant points, sharp and well defined. Knowing the distance of the cusps, or length of the chord, and also the semidiameters of the two bodies, the true distance of their centres at the instant the measure was taken can be calculated without much difficulty. As this measurement can be executed with much precision, and can also be repeated frequently during the progress of the eclipse, the phenomenon of a solar eclipse affords one of the most certain methods of determining a longitude which can be practised. *See* ECLIPSE.

5. *Transits of the Moon.* — This method is founded on the moon's rapid change of place among the stars, which becomes very sensible even in short intervals of time. Suppose an observer at the station A to determine the sidereal time of the transit of the moon's centre over his meridian; and suppose another observer at B, to the west of A, also to note the sidereal time of the same transit: if the moon's right ascension had in the interval undergone no change, the sidereal times marked by the two observers would have been the same; but as the right ascension has increased, while the moon was passing from the meridian of A to that of B, the sidereal time of the transit at the latter place will be increased; and, supposing the change of right ascension to be uniform, the difference of the times of transit will be proportional to the difference of meridians. The chief objection to this method is, that any minute error in the adjustment of the transit instrument or rate of the clock is thrown upon the longitude, on which it produces a very sensible effect. The method can, therefore, only be safely practised at fixed observatories with the best instruments.

6 *Moon-culminating Stars.*—This method has been proposed for the sake of eluding the effect of minute instrumental errors, which render the method last described so difficult. A star is chosen which *culminates* (that is, comes to the meridian) at nearly the same time with the moon, and which has very nearly the same declination; so that it may be seen in the field of view without altering the position of the transit instrument. The transit of the star, as well as the transit of the moon's limb, is observed at both stations (or at least observed at the one station, and calculated for the other whose meridian is known), and the difference of sidereal time between the two transits noted at each. This difference, in consequence of the moon's motion in right ascension, is not the same at both stations; and its variation gives the difference of the longitude. By this means any error of the position of the transit instrument affects the star and the moon both alike: but it is erroneous to suppose that the method is independent of accuracy in the adjustment of the transit instrument; for if the instrument is out of the meridian, the resulting longitude will be in error by the amount of the moon's variation in right ascension during the corresponding interval. This method is now much practised.

7. *Lunar Distances.*—None of the methods which have yet been described (excepting that by chronometers) can be applied to the very important problem of determining the longitude of a ship at sea. In this case, no fixed or meridian instrument can be employed; and the observer can only measure the apparent distance of the moon's limb from a fixed star or planet with a sextant, or some reflecting instrument which can be held in the hand. For the purpose of rendering this method available to seamen, the distance of the moon from certain fixed stars is computed (several years previously) for every three hours of Greenwich time, and published in the *Nautical Almanac.* The moon's distance from one of these stars being observed on board a ship, and corrected for refraction and parallax, and the apparent time at the place and moment of observation being determined in the usual manner by the altitude of the sun or a known star, the difference between the apparent time of the observation and the apparent time at Greenwich *corresponding to the same distance*, interpolated from the *Nautical Almanac*, gives the longitude of the ship. *See* LUNAR METHOD.

In the projection of maps and charts it is necessary to assume a point of the equator as the origin of the longitudes. The meridian passing through this point is called the *first meridian;* and as its selection is perfectly arbitrary, it has been placed by different geographers at various parts of the earth: a circumstance which occasions some inconvenience in consulting works of geography. Modern geographers usually assume the meridian of the capital of their own country as the first meridian. English writers generally adopt the meridian of the Greenwich Observatory, for which the *Nautical Almanac* is computed; the French that of the Observatory of Paris. (*See* MERIDIAN.) Ptolemy, and the most celebrated of the ancient geographers, placed the first meridian at the Fortunate Islands (now the Canaries), which they conceived to be the utmost boundary of the habitable earth. The Arabian astronomers also counted the longitude from the Fortunate Islands; and many of the modern geographers have counted from the island of Ferro, one of the most westerly of the Canaries. The reason for fixing on this point was probably that as there was no land known to the west of the first meridian, the longitudes of all places would be reckoned in the same direction, or there would be no west longitude. The discovery of America destroyed the force of this reason. The inconvenience of counting in two directions is not very great; but it might be avoided by reckoning the longitude all round the circle to 360°, which would undoubtedly be an improvement on the present method.

Degrees of Longitude. — The figure of the earth being spheroidal, the degrees of longitude diminish as we proceed from the equator towards either pole. For the law of their variation, and their lengths on the different parallel circles, see DEGREE.

Geocentric Longitude is the longitude of a planet as seen from the earth; that is, the point of the ecliptic to which it perpendicularly corresponds as seen from the centre of the earth.

Heliocentric Longitude is the longitude of a planet as seen from the sun. See the terms GEOCENTRIC and HELIOCENTRIC.

LO'NGUS CO'LLI. The name of a pair of muscles of the neck: when one contracts, it moves the neck to one side; when they both act, the neck is bent forwards.

LOOM. The well-known machine for producing cloth by the interweaving a series of parallel threads which run lengthwise, called the warp or chain, with other threads thrown transversely with the shuttle, called the woof or weft. Under the head WEAVING will be found a notice of the history of the loom, and the numerous improvements that have taken place in its construction from the earliest times down to the invention of Jacquard.

LOO'MING. The indistinct and magnified appearance of objects seen in particular states of the atmosphere. *See* MIRAGE.

LOO'PHOLES. In Fortification, apertures formerly made in the battlements, or in the walls of fortified places, for discharging arrows and javelins against the assailants. Since the invention of gunpowder, and the substitution of cannon for such missiles, loopholes have necessarily been discontinued in the construction of fortresses, the assailants of which are now sought to be driven back by guns fired through apertures of a different character, designated *embrasures*, which see.

LO'PHOBRA'NCHIATES, *Lophobranchii.* (Gr. *λοφος, a tuft; βραγχια, gills.*) An order of Osseous fishes, comprehending those in which the gills are in the form of small tufts, and disposed in pairs along the branchial arches; as in the pipe-fish and hippocamp.

LO'PHOTES. (Gr. *λοφος.*) A genus of Tænioid fishes, characterized by a short head, surmounted by a high osseous crest, to the summit of which a long and stout spine is attached, bordered behind with a membrane and a low fin, of which the rays are nearly all simple, and which extends from the occipital spine to the point of the tail; this is terminated by a distinct but very small caudal fin.

LOPHY'ROPODS, *Lophyropoda.* (Gr. *λοφυρος, crested; πους, a foot.*) The name of a section of Entomostracous Crustaceans, comprehending those species with cylindrical or conical ciliated or tufted feet.

LO'PPING. Cutting off all the branches of a tree for the sake of the profit to be derived from them; as contrasted with pruning, by which some of the branches are cut off for the sake of the tree. The lopping of a tree, however, does not include the cutting off of the crop or

leading shoot; and hence when timber trees are sold the purchaser bargains to take them either with or without the lop and crop, as the case may be.

LORANTHA'CEÆ. (Loranthus, one of the genera.) A natural order of parasitical Exogens, principally inhabiting the equinoctial regions of Asia and America. They are distinguished from *Caprifoliaceæ* and all other orders by their parasitical habit, and by the stamens being opposite to the petals. Brown suggests their relation to *Proteaceæ;* and, upon the whole, the structure of this order appears to be rather that of a polypetalous or apetalous than of a monopetalous order. Schleiden has lately made the startling assertion that they are gymnospermous. The bark is usually astringent. Their chief peculiarity is their power of rooting in the wood of other plants. They effect this when they first germinate by fixing their root upon the bark, and then by slow degrees introducing it into the tissue till they reach the wood, between the wedges of which they slightly insinuate themselves, thus placing their abortive roots in the line of the current of ascending sap. They are generally beautiful plants, but are scarcely capable of cultivation. Misletoe is the most northern species of the order.

LORD. A title of honour; said to be derived from two Saxon words signifying a giver or distributor of bread. It may be said to be either a title of hereditary dignity (as lord of parliament); or a title expressing certain powers, as lord of a manor, lord chancellor, lord of the treasury, &c. The eldest sons of earls, and all the sons of dukes and marquises, are styled lords by courtesy.

LORD-ADVOCATE OF SCOTLAND. *See* ADVOCATE.

LORD-KEEPER. *See* KEEPER, CHANCELLOR.

LORD-LIEUTENANT OF IRELAND. The chief executive officer of the Irish government, representing in some respects the person of the king. The first viceroy or lieutenant of Ireland appears to have been appointed in the reign of Henry II.; and by acts of parliament passed in the reigns of Richard III. and Henry VIII. provision was made for the election of a governor by the chancellor, treasurer, and other high officers of the government, on the death or resignation of a lieutenant, until the king's pleasure were known. The chief officer in Ireland has been variously styled at different times; as custos or keeper, justiciary, warden, procurator, seneschal, constable, deputy, and lieutenant. He is appointed by letters patent durante bene placito. He has a council, composed of the great officers of the crown in Ireland and others appointed by the crown. He corresponds with the secretary for the home department; but the management of the affairs of the Irish government in London is chiefly entrusted to the secretary for Ireland, who is also chief secretary of the lord-lieutenant. He has also a household, consisting of a private secretary, steward, comptroller, chamberlain, gentleman usher, master of the horse, and subordinate officers. His salary has been usually 20,000*l*. per annum.

LORD-LIEUTENANTS OF COUNTIES. In England and Wales, officers appointed by the king, and entrusted by parliament with full power and authority to call together, arm, and array the militia, and cause them to be trained and exercised once every year. Each may appoint twenty or more deputy lieutenants, who must have 200*l*. a year freehold estate; except in the Welsh and some small English counties, where the qualification is only 150*l*. The lord-lieutenant also nominates officers in the militia and yeomanry: but the names both of deputy-lieutenants and officers must be laid before the king; and if he, within fourteen days, expresses disapprobation, the commissions do not issue.

LORD PRIVY SEAL. *See* SEAL.

LORDSHIP. *See* LEET.

LORE (Lat. lorum, *a strap*), in Ornithology, signifies the space between the bill and the eye, which is bare in some birds, as the great crested grebe; but is generally covered with feathers. In Entomology the term is applied to a corneous angular machine observable in the mouth of some insects, upon the intermediate angle of which the mentum sits, and on the lateral ones the cardines of the maxillare, and by means of which the trophi are pushed forth or retracted, as in the Hymenopterous insects.

LORI'CA. (Lat. lorum, *a thong*.) A cuirass or crest of mail, made of leather and set with plates of metal in various forms, chiefly in rings like a chain, used by the Roman soldiers.

LO'RICATES, *Loricata*. (Lat. lorica, *a coat of mail*.) The name given by Merrem to an order of reptiles dismembered from the *Sauria* of Cuvier, and including those species, as the crocodile, which are protected by an armour of bony plates.

LORICA'TION. (Lat. loricare, *to crust over*.) A term of old chemistry, signifying the application of a lute or coating to glass and other vessels.

LORIS. *See* STENOPS.

LOSS. In Geology. *See* LOESS.

LOTE TREE (of the Ancients). Of this there were two kinds: the one a small plant, from which the *Lotophagi* derived their name; the other a tree with cut leaves and very hard wood. The former was the *Zizyphus lotus*, the latter the *Altis australis*. In the Hindoo mythology, the lote tree is regarded as the symbol of creation. *See* LOTOPHAGI.

LO'THIAN. A name common to that part of Scotland which stretches along a considerable part of the southern shores of the Frith of Forth, and comprehends the three counties, Haddingtonshire, Edinburghshire, and Linlithgowshire; otherwise called East, Mid, and West Lothian. The etymology of the name is doubtful. Lothian was taken possession of by the Saxon invaders A. D. 450, and became the scene of contest between the Saxon-Gaels and Scoto-Irish, and was at length ceded to Malcolm II. in 1020. Lothian was considered as a country wholly distinct from Scotland in the reign of David I., and the period of its incorporation with the rest of the country is assigned to the 11th or 12th century.

LO'TION. (Lat. lotum, supine of lavare, *to wash*.) A mixture of different ingredients, or a solution of various medicinal substances, in water or other menstrua, designed for external application. Indolent ulcers and tumours require stimulating lotions; whereas sedative and narcotic mixtures are used to alleviate pain.

LOTO'PHAGI. (Gr. λωτος, and φαγειν, *to eat*.) A name given to a people of ancient Africa who inhabited the Regio Syrtica (*Iber*. iv. 177.); so called from the lotus berry forming their principal food. They were represented as a mild hospitable race of men. The food with which they were nourished, among other peculiar qualities, is said to have had the power of obliterating all remembrance of one's native country.

LO'TTERY (Germ. loos, *lot*), is defined as a game of hazard, in which small sums are ventured for the chance of obtaining a larger value, either in money or other articles. Lotteries are formed on various plans; but in general they consist of a certain number of tickets drawn at the same time, with a corresponding number of blanks and prizes, by which the fate of the tickets is determined. The invention of lotteries has been ascribed to the Romans; by whom, however, they seem to have been resorted to as a means chiefly of amusing and gratifying the people. In modern times this species of gaming has been sanctioned at different periods by most of the European governments, as a means of raising money for public purposes. It would be difficult to give a complete account of the various changes which have taken place in the regulation of lotteries in different countries; but the subjoined summary of their history, from their origin down to their suppression in England, may not be uninteresting. The earliest English lottery of which there is an authentic record was drawn in 1569, when 400,000 tickets were sold at 10 shillings each. The prizes consisted chiefly of plate, and the net profits were intended to be appropriated to repairing the harbours of the kingdom and other public works. In the year 1612 a lottery was drawn for the benefit of the English colonies; and, in the course of the same century, the desire for embarking in speculations of this kind increased to such a degree, and gave rise to such an infinity of private undertakings, many of which were formed on the most delusive and fraudulent principles, that, in the beginning of Queen Anne's reign, parliament found it necessary to suppress *private* lotteries "as public nuisances." The year 1709 saw the birth of the first state or parliamentary lottery; and from that time down to 1823 they were annually licensed by act of parliament, under a variety of regulations and modifications. In the very early part of last century the prizes were paid in the form of terminable annuities. Thus in 1746 a loan of 3,000,000*l*. was raised on 4 per cent. annuities, and a lottery of 50,000 tickets, at 10*l*. each; and in the following year 1,000,000*l*. was raised by the sale of 100,000 tickets, the prizes in which were founded in perpetual annuities at the rate of 4 per cent. per annum. During the same century government constantly availed itself of this means to raise money for various public works, of which the British Museum and Westminster Bridge are well-known examples. But at the commencement of the present century a great repugnance began to be manifested in parliament to this method of raising any part of the public revenue, in consequence of the spirit of gambling which it tended to foster in the great body of the people; and notwithstanding the influence of the acts of 1778 and 1793, which were confessedly attended with much good, the evils to which it gave birth at last became so palpable that, in the year 1823, the legislature at last consented to the entire abolition both of state and private lotteries. It would be superfluous to enter into any argument to point out how prejudicial all such establishments must be to public morals, by giving the countenance of government to systematic gambling, no less than by diffusing a spirit of speculation by which the mind is misled from habits of continued industry to delusive dreams of sudden and enormous wealth, which, in the great majority of instances, must end in poverty and ruin. Those who

wish to see the melancholy results of this system of finance exhibited in its true colours, will find ample information in the two parliamentary reports presented to the House of Commons on the subject of lotteries in 1808; but we cannot refrain from inserting a paragraph from the *Wealth of Nations*, which illustrates their principle and operation with great brevity and effect:—

"The world neither ever saw, nor ever will see, a perfectly fair lottery, or one in which the whole gain compensated the whole loss; because the undertaker could make nothing by it. In the state lotteries, the tickets are really not worth the price which is paid by the original subscribers, and yet commonly sell in the market for twenty, thirty, and sometimes forty per cent. advance. The vain hope of gaining some of the great prizes is the sole cause of this demand. The soberest people scarce look upon it as a folly to pay a small sum for the chance of gaining 10 or 20,000 pounds; though they know that even that small sum is perhaps 20 or 30 per cent. more than the chance is worth. In a lottery in which no prize exceeded 20*l*., though in other respects it approached much nearer to a perfectly fair one than the common state lotteries, there would not be the same demand for tickets. In order to have a better chance for some of the great prizes, some people purchase several tickets, and others small shares in a still greater number. There is not, however, a more certain proposition in mathematics, than that the more tickets you adventure upon the more likely you are to be a loser. Adventure upon all the tickets in the lottery, and you lose for certain; and the greater the number of your tickets, the nearer you approach to this certainty." (See also *Degerando's Bienfaisance Publique*, l. ii. ch. 6.)

State lotteries were abolished in France in 1836, along with the gambling houses, from which a great revenue had been derived. They still exist in several of the German states. That of Hamburg is established on a comparatively fairer principle than was adopted either in France or England; the *whole* money for which the tickets are sold being distributed among the buyers, except a deduction of 10 per cent. made from the amount of the prizes at the time of their payment. See *Penny Cyclo*.

LOUGH. An Irish term, synonymous with the Scotch *loch*, but not with the English *lake*; for loch and lough are applied to designate arms of the sea, as well as collections of fresh water, which lake is not.

LOUIS D'OR. A gold coin under the old system of France, first struck under Louis XIII. in 1641, from whom they derived their name. The louis d'or, says Kelly, coined before 1726, which passed then for 20 livres, were coined at the rate of 36¼ per French mark of gold 22 carats fine. From the year 1726 to 1785 louis d'ors were coined at the rate of 30 to the mark of gold; and about this period all the gold coins in France were ordered to be brought to the mint to be melted down; and a new coinage then took place, at the rate of 32 louis d'ors to the mark of the same degree of fineness, with a remedy of 15 grains in the weight, and $\frac{12}{32}$ of a carat in the alloy. The intrinsic value of this new coin was 18*s*. 9¼*d*. sterling. Louis d'ors were formerly regarded as a current coin in all parts of the Continent; but in England they are sold merely as merchandise, and their value has fluctuated from 18*s*. 6*d*. to 21*s*. sterling. The term louis d'or is still given to the gold coinage of the present dynasty of France, though they are also often called 20-franc pieces.

LOUIS, SAINT, OF FRANCE. A royal military order, founded by Louis XIV. in 1693. The badge is a cross of eight points, with fleur-de-lis, and bearing a circular shield containing the effigy of Saint Louis.

LOU'VRE. One of the most ancient palaces of France. It existed in the time of Dagobert as a hunting seat, the woods then extending all over the actual site of the northern portion of Paris down to the banks of the Seine. The origin of its name has not been satisfactorily ascertained. It was formed into a stronghold by Philip Augustus, who surrounded it with towers and fosses, and converted it into a state prison for confining the refractory vassals of the crown. It was then without the walls of Paris; but, on their extension in the latter part of the 14th century, it was included within their circuit. Charles V. made additions to it. That part of the palace now called the *Vieux Louvre* was commenced under the reign of Francis I., after the designs of Pierre L'Escot, abbot of Clugny. When Charles IX. resided in the Louvre, he began the long gallery which connects it with the Tuilleries, and in which is now deposited the celebrated collection of pictures. It was finished under Henry IV. Louis XIV., from the designs of Lemercier, erected the peristyle which forms the entrance to the Vieux Louvre from the side of the Tuilleries. That monarch also gave a beginning to the remainder of the present modern edifice, from the designs of Claude Perrault. The edifice has never been finished; though, under the reigns of succeeding monarchs, and especially during that of Napoleon, it has slowly advanced towards completion. The eastern front, though not finished even now, exhibits a façade of surpassing beauty,—perhaps, in its kind, never equalled. The quadrangle of the Louvre is a perfect square on the plan. Three of its sides were from the designs of Perrault, above mentioned. An immense expenditure will be necessary to connect the Louvre with the Tuilleries, to which it is joined at present only on the river side by the great gallery above mentioned; but preparations are in progress to effect this object, and on the side next the Rue St. Honoré about 1400 feet have been executed. Besides the gallery above adverted to, which contains some of the finest pictures in the world, the Louvre contains a museum of sculpture, antiquities, and other specimens of art, equally valuable.

LOVE, FAMILY OF. A sect of fanatics in the 16th century, holding tenets resembling those of the early Anabaptists. There is a proclamation against them by Queen Elizabeth, dated from her manor of Richmond, 1580.

LOVE FEASTS. A species of religious ordinanee held quarterly by the Methodists, to which members of their church alone are admitted, and that only on presenting a ticket or a note from the superintendent. They are a relic of the *Agapæ* (which see) held by the early Christians.

LOWER CHALK AND GREENSAND. *See* GEOLOGY.

LOWER EMPIRE. The Roman empire, from the removal of the imperial seat to Constantinople, and its successor, the Byzantine empire, down to the capture of that city by the Turks, are frequently joined together under this name by modern historians.

LOW SUNDAY. In Ecclesiastical Antiquities, the Sunday next after Easter has been popularly so called in England; perhaps by corruption for *close* (Pascha clausum, *close of Easter*, one of the many names by which it was known in the Christian church). (*Riddle's Christ. Ant.* 640.)

LO'XIA. (Gr. λοξος, *crooked*.) A genus of Conirostral Passerine birds, characterized by having a compressed beak, and the two mandibles so strongly curved that their points cross each other, sometimes on one side, sometimes on the other. The crossbill (*Loxia curvirostra*) is the type of this genus.

LOXODRO'MIC CURVE or SPIRAL (Gr. λοξος, *oblique*, and δρομος, *course*), is a kind of logarithmic spiral traced on the surface of a sphere: the meridians which it intersects all under the same angle being regarded as the radii of the spiral. It is the path which a ship sailing always on the same rhumb, or making the same angle with the meridians, describes on the surface of the terrestrial sphere. The properties of the curve are analogous to those of the common logarithmic spiral. It always approaches the pole, but never reaches it; so that a ship, by following always the same oblique course, would continually approach the pole of the earth without arriving at it. To find the equation of the loxodromic, let φ be the arc of the meridian intercepted between any point of the curve and the pole, and λ the longitude of that point; then the infinitely small arc of the parallel of latitude corresponding to an increment of the curve is $d\lambda$ sin. φ, and the differential of the co-latitude is $d\varphi$; but, because the curve cuts all the meridians under the same angles, the variation of the parallel of latitude corresponding to an increment of the curve is proportional to the variation of the co-latitude; consequently $a\,d\lambda \sin.\varphi = d\varphi$, or $a\,d\lambda = \frac{d\varphi}{\sin.\varphi}$, which is the differential equation of the loxodromic, a being a constant quantity.

LO'ZENGE. An oblique-angled parallelogram, or rhombus, formed by construcrting two equal isosceles triangles upon opposite sides of the same straight line.

LOZENGE. In Heraldry, a bearing in the shape of a parallelogram, with two obtuse and two acute angles. The arms of maidens and widows are borne on shields of this shape.

LOZENGE. In Pharmacy, a medicinal substance made up into a small cake gradually to be dissolved in the mouth. Sugar, gum, and starch are the usual inert parts of lozenges; and minute quantities of active substances are added, according to the purposes for which they are intended: such as ipecacuanha or squills, for pectoral lozenges; extract of poppies or opium, for sedative lozenges; kyan pepper as a stimulant; oil of peppermint as an antispasmodic, &c.

LUCA'NIDÆ. (Gr. λυκος, *a wolf*; also the name of an insect.) A family dismembered from the Linnæan genus *Lucanus*, and including those insects which, in addition to the comprehensive characters of the original genus, present antennæ strongly geniculate, glabrous, or but slightly pilose; the labrum very small, or confounded with the epistome; maxillæ terminated by a membranous or coriaceous, silky, pencilliform lobe; edentate, or with one tooth; and a ligula either entirely concealed or incorporated with the mentum, or divided into two narrow, elongated, silky lobes, extending more or less beyond the mentum. The scutellum is situated between the

elytra. The stag-beetle, *Lucanus cervus*, &c., is the type of this family. The sub-genera are *Œsalus*, *Lamprina*, *Sinodendrum*, &c.

LUCA'NUS. (Gr. λυκος.) A Linnæan genus of Coleoptera, forming the type of a tribe of Lamellicorn beetles (*Lucanina*), in the system of Latreille, by whom it is thus characterised:—Antennæ composed of ten joints, the first of which is usually much the longest; the antennal club has its leaflets or teeth arranged perpendicularly to its axis, in the manner of a comb. The mandibles are always corneous, and most commonly exhibit a sexual superiority of development and peculiarity of form in the males. The maxillæ are generally terminated by a narrow, elongated, and silky lobe; but sometimes are entirely corneous and dentated. The ligula in most of the *Lucanines* is formed of two small silky pencils, projecting more or less beyond an almost semicircular or square mentum. The anterior legs in the greater number are elongated, and their tibiæ dentated along the whole of their outer side. The tarsi terminate in two equal and simple hooks, with a little appendage with two setæ between them. The elytra cover the whole of the upper part of the abdomen. The insects thus characterised were first divided by the immediate successors of Linnæus into two genera, *Lucanus* proper and *Passalus*, both of which are now elevated to the rank of families, and subdivided into numerous subgenera. *See* Lucanidæ and Passalidæ.

LU'CERES. (Lat.) In Roman antiquities, a body of horse composed of Roman knights, first established by Romulus and Tatius. It is said to have received its name either from an Etrurian, who aided the Romans against the Sabines; or from the Lat. *lucus*, a grove, where Romulus had instituted an asylum for all fugitives, slaves, and homicides, in order that he might people his infant city: but it is difficult to account for the real origin of the word.

LUCE'RN. (*Medicago sativa.*) A well-known plant of the Linnæan class Diadelphia, and order Decandria, and of the natural family of the *Leguminosæ*. There are many species of the Medicago, but of these the artificial grass, called Lucern, is most deserving of notice. This plant was in high estimation among the ancients; and its nutritious qualities, easy cultivation, rapid growth, and luxuriant properties, have placed it in the first rank of vegetable food for cattle, even in the present times. Lucern, says an old writer, is commended for an excellent fodder. . . . There is not any pulse or other feeding which is more agreeable or more precious for feeding beasts than lucerne: so that it may seem to spring out of the earth. . . as a more especial favour from God, not only for nourishing and fattening herds of cattle, but also to serve as a physic for beasts that are sick. (*Country Farm*, 3d edit. fol. 1616, p. 364.) Those who wish to see the properties of this plant fully developed at once from the author's personal experience, and the concurrent testimony of the best agricultural writers both ancient and modern, and its history traced from its discovery during the Persian expedition under Darius to its subsequent introduction successively into Greece, Italy, Spain, France, Germany, and, in fact, wherever the art of husbandry has made any progress, down to its arrival in England, will find ample details in the learned *Essays on Husbandry* by the Rev. Walter Harte (London, 1770), to which we beg to refer. The origin of the term lucern is involved in obscurity. Some authors have derived it, naturally enough, from the canton in Switzerland of that name; but from the account given by Mr. Harte of the history of this plant, it does not appear either that Switzerland was particularly famous for producing it, or that the northern and western nations of Europe received it thence.

LUCERNA'RIA. (Lat. lucerna, *a lamp.*) A genus of fleshy polypi (*Polypi carnosi*) in the system of Cuvier, characterised by a long and slender pedicle supporting a radiated disc, which sends off numerous tentacula united in bundles. The *Lucernariæ* Cuvier regards as being nearly allied to the *Actineæ* or *sea-anemones;* but their substance is softer. They emit phosphorescent light.

LU'CIFER. (Lat. lux, *light;* fero, *I bring.*) The morning star. A name given to the planet Venus, when she appears in the morning before sunrise. When Venus follows the sun, or appears in the evening, she was called *Hesperus*, the evening star. These names no longer occur except in the old poets.

Lu'cifers. Matches tipped with a mixture of chlorate of potash and sulphuret of antimony: they are inflamed by friction upon a piece of emery paper.

LUCIFE'RIANS. The name of an ancient sect of heretics, so called from Lucifer, bishop of Cagliari, in the 4th century, whose opinions they embraced. The Luciferians considered the soul to be of a carnal nature and to be transmitted from father to child; but the chief occasion of the schism of Lucifer arose from his refusal to hold any communion with the clergy who had conformed to the Arian doctrines, and whom a synod at Alexandria, A.D. 352, had determined to re-admit into the church on condition of an open acknowledgment of their errors. The number of this sect was never considerable, and it was extinct in the time of Theodoret; but it deserves notice from being considered by the Roman Catholics as one of the great schisms in their church. *See* Schism.

LUCI'NA. In Roman Mythology, the goddess who presided over the birth of children. Her name is derived either from *lucus* or *lux*, according to Ovid's explanation,—

> Gratia Lucinæ, dedit hæc tibi nomina lucus;
> Aut quia principium, tu, Dea, lucis habes.

She is said to be the daughter of Jupiter and Juno; and has frequently been confounded with Diana and Juno, both of whom presided over childbirth. She was called Ilithya by the Greeks.

LUCU'LLITE. A black limestone, often polished for ornamental purposes, to which it is said first to have been applied by Lucullus, the Roman consul.

LU'ES. (Lat.) A poison or pestilence; a plague.

LUFF. The foremost edge or leach of a fore-and-aft sail. *To luff*, to bring the ship's head nearer the wind.

LU'FFER BOARDING. (Fr. louvre.) In Architecture, boards in an aperture placed above each other at regular distances, and inclined to the horizon at an angle of forty-five degrees, so as to admit air without allowing the rain to penetrate.

LUG-SAIL. A four-sided sail bent to a yard, which is slung about one fourth from the lower end.

LU'MACHE'LLA. Shell marble; the fragments having a pearly lustre, it is sometimes termed *fire marble*.

LUMBA'GO. *See* Rheumatism.

LUM'BAR A'BSCESS. An abscess of the loins formed upon the psoas muscle: it is frequently mistaken for nephritic or rheumatic disease, and, when it forms a swelling in the groin, for hernia.

LUMBRICAL MUSCLES. (Lat. lumbricus, *an earthworm.*) Small muscles of the hand which assist in bending the fingers.

LU'MBRICUS. (Lat.) A Linnæan genus of Vermes, now the type of a family (*Lumbricinæ*) which ranks as the first of the Setigerous Abranchian Anellidans in the system of Cuvier. All the species of this family—the earthworms, as they are commonly called—are characterized by a long cylindrical body, divided by rugæ into a great number of rings, and by an edentate mouth. The common earthworm (*Lumbricus terrestris*, Linn.) attains nearly a foot in length, and is composed of upwards of one hundred and twenty rings. This species is extremely abundant: they traverse the soil in every direction, swallowing quantities of earth, together with portions of roots and ligneous fibres, and other organized substances, which they assimilate for their own nutriment. Their castings constitute a rich soil.

LUNA. (Lat. *the moon.*) In Mythology, the daughter of Hyperion and Terra, usually confounded with Diana, which see. The heavenly bodies were favourite objects of worship among the ancients; and as they considered the sun to be sacred to Apollo, whom they worshipped as Sol, so they consigned the moon to the guardianship of his sister Diana, whom they worshipped under the name of Luna.

LU'NA CO'RNEA. Fused chloride of silver; so called from its horn-like appearance, luna being the term by which the old chemists designated silver.

LU'NACY, in Law, is strictly the condition of an insane person who has lucid intervals, which in former times were supposed to depend on the phases of the moon; whence such persons were styled *lunatici*. But, for convenience, the term is commonly used as embracing the condition of all those who are under certain legal disabilities on account of mental deficiency: such as idiots, fatuous persons, &c.; all, in short, who are of unsound mind. The chief of these disabilities are, incapacity to make contracts, either personal or affecting the estate; to sue or defend in courts of justice; to perform offices and duties; to make devises or bequests. By ancient legal maxim, the sovereign has the custody of lunatics. This is in practice delegated to the keeper of the great seal, by virtue of the sign manual, countersigned by two secretaries of state. Applications for a commission of lunacy are consequently directed to him. When he determines that such a commission is proper, it issues to certain commissioners, appointed by the same authority. They summon a jury to try the fact of lunacy. If the party is found lunatic by its inquisition, the inquisition may still be avoided by a traverse; on which the record goes into the King's Bench, which either gives judgment or grants a new trial on it. If the lunatic recover, the inquisition may be superseded. On the return of the inquisition, the custody of the lunatic's person and estate devolves on the crown; and the chancellor, on petition, appoints *committees* to have the custody of either or both. These may be whoever the chancellor thinks fit, although next of kin are ordinarily preferred. Lunatics are maintained by an allowance out of their own estate: when they have none, by statute, in public asylums. The custody of lunatics by private individuals is under the contro of the provisions of the stat. 3 & 4 W. 4. c. 36., by

which visitors are empowered once a year to inspect their condition. Licensed houses for the reception of lunatics, under the keeping of medical men, are within the regulations of 2 & 3 W. 4. c. 107., under the inspection of licensing commissioners. Persons of unsound minds who are paupers, and those who have been tried for offences and found insane, and also lunatic convicts, are usually confined in county lunatic asylums, wherever these are established. As to the statistics of lunatic hospitals or asylums, see *Degerando, de la Bienfaisance Publique*, vol. iv. part 3. book 3.

The incapacity of a person of unsound mind to commit a crime depends, it is said, upon his irresponsibility, moral and legal. The general mode of directing a jury has been to acquit the prisoner, if satisfied that he was incapable of knowing right from wrong; or, as some eminent judges have worded it, if he was unconscious that the act was a crime against the laws of *God and nature*. On acquittal taking place on evidence of lunacy, the jury are now required, by 39 & 40 G. 3 c. 94., to find specially whether the person was insane at the time of commiting the offence; and on that finding he is taken into public custody.

LU'NAR BONE. One of the bones of the wrist.

LU'NAR CAUSTIC. Fused nitrate of silver.

LU'NAR CYCLE. The period of time after which the new moons return on the same days of the year. *See* CYCLE.

LU'NAR DI'STANCE. In Navigation, the distance of the moon from the sun, or from a fixed star or planet; by means of which the longitude of a ship is found.

LU'NAR ME'THOD. In Astronomy and Navigation, the method of determining the longitude of a place or ship from the observation of *lunar distances*. This problem, which is of the very highest importance, on account of its being the only astronomical method of finding the longitude practicable at sea, resolves itself into two parts. The first is to ascertain the distance of the moon's centre from one of the principal planets or fixed stars at a given moment; and the second, to find the Greenwich time to which, according to the tables, that distance corresponds. The general method of procedure may be explained as follows: — Six or eight observations of the star's distance from the nearest point of the moon's limb are taken with a sextant as quickly in succession as possible, and the corresponding time at each observation noted: the mean of the observed distances, at the mean time, gives a single distance corresponding to a known instant of time. The true apparent time is here supposed to be given by the chronometer, the rate and error of which are determined by observations of altitude. Contemporaneously with the observations of distance two assistants are employed in taking the altitudes both of the moon and star, for the purpose of applying the proper correction for refraction. The remainder of the operation consists in making the requisite calculations. In the first place, the moon's semidiameter is added to the observed distance, whereby the true apparent distance is found. In the next place, the corrections are applied for refraction and parallax, and the apparent distance reduced to the centre of the earth. This part of the operation is technically called *clearing the distance*. The computer then turns to the *Nautical Almanac*, in which the distances of the moon from some of the principal stars and planets is given for every three hours. Having found in the almanac the distances next less and greater than the true distance deduced from the observations, their difference gives the change of distance in three hours; whence, by interpolation, the Greenwich time is obtained at which the distance was exactly the same, and consequently the Greenwich time corresponding to the apparent time at the instant of the observation.

This method of finding the longitude at sea was first proposed by John Werner of Nuremberg so early as 1514, and recommended by several other astronomers who lived during the same century; but the theory of the lunar motions was then, and for a long time after, by far too imperfect to allow of its practical application. Besides, previously to the invention of Hadley's quadrant, there was no instrument by which the distances could be measured with the requisite precision. The advancement of astronomy, and the perfection of instruments of observation, have obviated all difficulties; and the method of lunar distances is now mainly relied on by the mariners of all countries.

LUNAR MONTH. The time in which the moon completes a revolution about the earth, and returns to the same position relatively to some celestial body, or point in space, with which her motion is compared. But the moon's period may be determined in relation to several objects, — as the sun, the equinoctial points, a fixed star, the perigee or nodes of her orbit; and accordingly there are as many different lunar months as there are assumed points of comparison, provided these points have different motions in the heavens.

1. The proper *lunar month* is the same as the *lunation* or *synodic month*, and is the time which elapses between two consecutive new or full moons, or in which the moon returns to the same position relatively to the earth and sun.

2. The *periodic month*, or *synodic month*, is the revolution with respect to the moveable equinox.

3. The *sidereal month* is the interval between two successive conjunctions with the same fixed star.

4. The *anomalistic month* is the time in which the moon returns to the same point (for example, the perigee or apogee) of her moveable elliptic orbit.

5. The *nodical month* is the time in which the moon accomplishes a revolution with respect to her nodes, the line of which is also moveable.

The exact *mean* lengths of these different lunar months are as follow: —

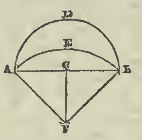
	days.	h.	m.	sec.
Synodic month - -	29	12	44	2·84
Tropical month - -	27	7	43	4·71
Sidereal month - -	27	7	43	11·54
Anomalistic month - -	27	13	18	37·40
Nodical month - -	27	5	5	35·60

These *mean* motions are not uniform, but are subject to periodic and secular variations. *See* MOON.

LU'NAR YEAR, is the period of twelve synodic lunar months, and consequently contains 354 days; the lunar months in the calendar being alternately 29 and 30 days. The exact period of 12 lunar months is 354 days, 8 hours, 48 min. 34 sec.; so that the lunar year of the calendar requires to be adjusted by intercalation every third year. *See* CALENDAR.

LUNA'TION. The period of a synodic revolution of the moon, or the time from one new moon to the following, being that in which the moon passes through all her phases.

LUNE, or LU'NULA. A geometrical figure in form of a crescent, bounded by two arcs of circles intersecting at its extremities. The lunula of Hippocrates, of Chios, is celebrated on account of a remarkable property discovered by that geometer; namely, that it can be exactly squared, though the quadrature of the whole circle has baffled the ingenuity of mathematicians of all ages. Let A D B be a semicircle whose centre is at C, and A E B a quadrant of another circle whose centre is at F (C F being perpendicular to the diameter A B); then the space contained between A D B and A E B is the lune of Hippocrates, and it is equal to the area of the triangle A F B. For the square of A F being equal to the squares of A C and C F, or twice the square of A C, and circles being to one another as the squares of their radii, the whole circle of which A F is the radius is equal to twice the circle of which A C is the radius; and consequently the area of the quadrant A E B F is equal to the semicircle A D B. Take away the common space A E B A, and there remains the triangle A B F, equal to the lune.



LUNE'TTE. (Fr.) In Fortification, an enveloped counterguard or elevation of earth, made beyond the second ditch, opposite to the place of arms; differing from the ravelins only in situation. *Lunettes* are also works made on both sides of a ravelin. *See* FORTIFICATION.

LUNETTE. In Architecture, an aperture for the admission of light in a concave ceiling; such are the upper lights to the naves of St. Peter's at Rome and of St Paul's at London.

LUNGS. (Germ. lungen.) The viscera by which respiration is carried on. The right lung is divided into three lobes, the left into two. They are, as it were, suspended in the chest by the *trachea*, and separated by the *mediastinum*; they are also attached to the heart by the pulmonary vessels. They are nourished by the bronchial artery, which is a branch of the aorta; and the pulmonary artery carries the venous blood through them from the heart, to subject it to the action of the air in their cellular structure: the blood when arterialized returns to the heart by the pulmonary veins, the four trunks of which enter the left auricle. The bronchial veins terminate in the vena azygos. The nerves of the lungs are from the eighth pair and great intercostal.

LU'NISO'LAR. (Lat. luna, *the moon*, and sol, *the sun*.) Combining the motions of the sun and moon. A lunisolar period is that after which the eclipses again return in the same order. (*See* CYCLE.) The Dyonysian period of 532 years, formed by multiplying together the solar and lunar cycles of 28 and 19 years, has sometimes been called the lunisolar year.

LUPERCA'LIA. A Roman festival in honour of Pan, celebrated in February; when the Luperci ran up and down the city naked, having only a girdle of goat's skin round their waist, and thongs of the same in their hands, with which they struck those they met, particularly married women, who were thence supposed to be rendered prolific. The name is derived from lupus, *a wolf*; because Pan protected cattle from that animal.

The indecencies and excesses attending the processions of the Lupercals, which had degenerated from high religious rites to vulgar superstitions, provoked the indignation of Christians in the 4th and 5th centuries. It is commonly, but erroneously, supposed that pope Gelasius caused them to be abolished. (*Gibbon*, vol. vi.) Beugnot has shown the contrary. (*Destr. du Paganisme en Occident*, book xix. ch. 2.)

LUPE'RCI. The Roman priests of Pan, and most ancient religious order in the state, having been instituted, according to tradition, by Evander, king of Pallantium, a town that occupied the Palatine Hill before Rome was built. There were three companies of them; viz. the Fabiani, Quintiliani, and Julii — the last of whom were founded in honour of Julius Cæsar. For the derivation of the word see LUPERCALIA.

LU'PINITE. A bitter substance, extracted from the leaves of the white lupin.

LU'PULIN. The active principle of the hop; it is more properly called *lupulite*.

LU'PUS. (Lat.) The wolf. One of the southern constellations, situated on the south of Scorpio.

LU'PUS. In Pathology, a disease which eats away the parts attacked by it with great rapidity.

LU'SIAD. The name given to the great epic poem of Portugal, written by Camoens, and published in 1571. The subject of this poem is the establishment of the Portuguese empire in India; but whatever of chivalrous, great, beautiful, or noble, could be gathered from the traditions of his country, has been interwoven into the story. Among all the heroic poets, says Schlegel, either of ancient or modern times, there has never, since Homer, been any one so intensely national, or so loved or honoured by his countrymen, as Camoens. It seems as if the national feelings of the Portuguese had centered and reposed themselves in the person of this poet, whom they consider as worthy to supply the place of a whole host of poets, and as being in himself a complete literature to his country. Of Camoens they say,

> Vertere fas; æquare nefas; æquabilis uni
> Est sibi; par nemo; nemo secundus erit.

The great defects of the *Lusiad* consist in its preposterous mythological machinery, and its clumsy management; but in all the qualities of versification and beauty of language it is perfect, and may be regarded as the "well, pure and undefiled," of the Portuguese language.

Few modern poems have been so frequently translated as the *Lusiad*. Mr. Adamson, whose *Memoirs of the Life and Writings of Camoens* must be familiar to the reader, notices one Hebrew translation of it, five Latin, six Spanish, four Italian, three French, four German, and two English. Of the two English versions one is that of Sir R. Fanshawe, written during Cromwell's usurpation, and distinguished for its fidelity to the original; the other is that of Mickle, who, unlike the former, took great liberties with the original, but whose additions and alterations have met with great approbation from all critics — except, as indeed was to be expected, from the Portuguese themselves. (See the *Quarterly Review*, vol. xxvii.)

LUSTRA'TION. (Lat. lustro, *I purify*.) In Roman Antiquities, a sacrifice by which the Romans purified their cities, fields, armies, or people, defiled by any crime or impurity. There were various manners of performing this ceremony, according to the nature of the lustration. When Servius Tullius had numbered the Roman people, he purified them, as they were assembled in the Campus Martius, by causing a young pig, a sheep, and a bull, just sacrificed, to be paraded round them. Before the celebration of the Ludi Seculares, which took place only once in a century, the *populace* was purified by a little sulphur, bitumen, and perfume, fixed to a piece of fir called *tæda*, which was lighted, and which thus circulated the smoke around them. The *army* was purified by causing the soldiers to defile between the two quivering halves of a victim, while the priest offered up certain prayers. The lustration of a funeral pile was effected by making the spectators march round it before the fire was kindled. (See *Memoires de l'Ac. des Inscriptions*, vol. xxxvi.) *See* AMBARVALIA.

LU'STRUM. (Lat.) In Roman Antiquities, a space of about five years: at the end of which period the feast called Lustralia was celebrated, in which the censor purified the people by several sacrifices and ceremonies; among others, the *suovetaurilia*, or sacrifice of a hog, sheep, and goat. It appears that rather more than five years usually elapsed between one lustralia and the next; but the word lustrum is usually employed for the exact quinquennial period. The derivation of the word is uncertain. Lustrare, in Latin, signifies to purify by a solemn ceremony: and many other lustral ceremonies were in use; as, for example, the *dies lustrales*, or lustral days, being the fifth, or according to some writers the eighth, day after the birth of a child, on which it was purified with certain solemnities, named, and placed under the protection of the gods of the family; the *lustration* of sheep in April, the crops in May, &c., of which so many are continued in the Roman Catholic worship of modern times. Sea-water was the most ordinary article used in lustrations. Varro derives the word lustrum from luere, *to pay*; because, according to the custom ordained by Servius Tullius, who first instituted the census (566 B.C.), the tribute imposed by the censors was paid at the beginning of every fifth year, the last of the lustrum. (See an Essay in the *Mémoires de l'Ac. des Inscr.* vol. xxxix.; and *Niebuhr's History*.)

LU'SUS NATURÆ. (Lat. *a sport of nature*.) A term applied to any thing unnatural in the physical world.

LUTE. (It. liuto.) A musical stringed instrument of the guitar species, and played in a similar way; but in form more resembling the section of a pear, with a back in ribs, like those of a melon.

LUTES, in Chemistry, applications by which the junctions of vessels are rendered tight. A glass retort is said to be *luted* when smeared over with clay, so as more perfectly to resist the effects of heat, and to prevent its fusion. Common lute is a mixture of pipe-clay, linseed meal, and water, and is spread upon paper and applied to the joinings of stills and of retorts and receivers. *Fat lute* is a mixture of pipe-clay and linseed oil.

LU'THERANS, or FOLLOWERS OF LUTHER. The denomination of Christians whose religious system had its origin in the preaching of Luther. This system in some respects approaches nearer to Romanism than that of any other of the reformed churches. The notions of Luther upon the nature of the Eucharist are known under the name of consubstantiation, or the coexistence of the body and bread, the blood and the wine, at the same time. It encourages also the private confession of sins, makes use of wafers in the administration of the Lord's Supper, and allows of images in churches. It insists, however, very strongly upon Luther's cardinal doctrine, the justification of man by faith, and not by any merit in human actions. With respect to the divine decrees, it holds that God foreknows the dispositions of men, whether they will be good or bad, and predetermines their salvation or rejection accordingly; differing therein from the tenet of the Calvinists, which represents the Supreme Being as making his decrees by his own mere will. The dogmas of the Lutheran church are carefully set forth in various symbolic books: the *Confession of Augsburg*, the *Articles of Smalcald*, the Shorter and Larger Catechisms of Luther, and the *Form of Concord*. The principle, however, of this church, which considers Christians as accountable to God alone for their religious opinions, allows its teachers, at the present day, an unbounded liberty of dissenting from these decisions. The Lutheran church predominates in the north of Germany, in Prussia, Norway, Denmark, and Sweden: there are congregations also of the same denomination in England, Holland, Russia, and America. In the Prussian dominions it has been remodelled under the late king, and is called the Evangelical Church. *See* CHRISTIANITY.

LU'THERN. (Fr.) In Architecture, the same as *dormer*, which see.

LU'TRA. (Lat. *an otter*.) A genus dismembered by Storr from the Linnæan *Mustela*, and now raised to the rank of a family (*Lutridæ*).

LUXA'TION. (Lat. luxare, *to put out of joint*.) A dislocation of a bone.

LYCA'NTHROPY. (Gr. λύκος, *a wolf*, and ἄνθρωπος, *a man*.) Herodotus relates that the Neurians, a Scythian tribe, were supposed to be changed, for a certain number of days every year, into wolves, and then to resume their former shape; and a similar superstition is noticed by Virgil in his *Eclogues*, by Pliny, Pausanias, and other writers. The same superstition, of the power possessed by men of converting themselves into wolves, remained in more modern times; but that which the classical ancients had believed to be effected by the power of herbs, or by innate powers, was by Christians considered as a species of sorcery. These human wolves were called loup-garoux by the French, were-wolves by the Anglo-Saxons, wehrwölfe by the Germans: words of the same derivation, and bespeaking that the superstition in those countries was of Teutonic origin. They were believed to be extremely ferocious, and to devour not only beasts, but human beings; but if they were pursued and wounded, the spell was frequently dissolved, and the sorcerers were found mutilated in those limbs in which they had received the wound in their wolfish shape. From the prevalence of these superstitions in the minds of an ignorant peasantry originated the hideous species of madness termed *lycanthropy*, in which the patient believed himself to be a wolf, and frequently imitated the actions and howl of that animal. In France, in the 16th century, numbers of these unfortunate beings were executed, like witches, on their own confession; and in the avowals which they made, of having killed and devoured mankind, they were probably not always under a delusion. Some of these maniacs declared that they were actually wolves; but that in them the hair grew inside, or between the skin and the flesh. Oribasius, who lived in the fifth century of our era, mentions lycanthropy by its true cha-

racter as a species of madness, and describes the symptoms and the cure. This species of insanity seems to have gradually died away along with the superstition which gave it birth. (See a curious article in the *Enc. Metropolitana.*)

LYCE'UM. An academy at Athens was so termed, from its situation near the temple of Apollo Lyceus. It was frequented, according to tradition, by Aristotle. Preparatory schools for the universities, in which the Aristotelian philosophy was formerly taught, hence received on the Continent the name of Lyceum.

LY'CHNITES. An ancient name of marble; from λυχνος, its quarries being worked by lamp-light.

LY'COPO'DIA'CEÆ. (Lycopodium, one of the genera.) A natural order of Acrogens, inhabiting all parts of the world, but abounding chiefly in hot humid situations. They are intermediate, as it were, between ferns and coniferæ on the one hand, and ferns and mosses upon the other. *Lycopodium rubrum* is a violent cathartic; *clavatum* and *selago* excite vomiting; and the powder contained in the seed-vessels of all the species is so highly inflammable as to be employed occasionally in the manufacture of fireworks. They are propagated by spores formed in two-valved cases axillary to the upper leaves.

LY'COPO'DIUM. A fine yellow dust or powder, being the seed of the *Lycopodium clavatum*, or club moss: when thrown into the flame of a candle, or of spirit of wine, it burns with a bright flash. It is much sought after for producing theatrical lightning, and is an excellent substance to sprinkle upon pills to prevent their adhering.

LYCO'SA. (Gr. λυκος, *a wolf.*) A genus of spiders, in which the eyes form a quadrilateral group, as long as or longer than it is wide; the two posterior eyes not placed on an elevation. The first pair of legs is evidently longer than the second, but shorter than the fourth, which is the shortest of all. The internal extremity of the jaws is obliquely truncated. Almost all the *Lycosæ* keep on the ground, where they run with great swiftness. They inhabit holes in the ground, which they line with silk, and enlarge in proportion to their growth. Some establish their domicile in chinks and cavities in walls, where they form a silken tube, covered externally with particles of earth or sand. In these retreats they change their tegument; and, as it appears, after closing the opening, pass the winter in a state of torpidity. The females, when they go abroad, carry with them their eggs enveloped in a cocoon attached to the abdomen by threads. On issuing from the egg, the young ones cling to the body of the mother, and remain there until they are able to provide for themselves. The *Lycosæ* are extremely voracious, and courageously defend their dwelling. The famous Tarantula spider is a species of this genus.

LY'DIAN STONE. A silicious slate, used by the ancients as a touchstone, from Lydia.

LY'ING PANELS. In Architecture, those in which the fibres of the wood lie in an horizontal direction.

LYING-TO. A nautical term, denoting the state of a ship when the sails are so disposed as to counteract each other, and thereby retard or destroy the progressive motion of the vessel. The fore and main staysails and mizen trysail serve very well for this purpose, as they cause but little way, and have sufficient power to keep the ship heeled over, and therefore steady, with her decks turned from the sea. When the sea runs very high, the lower sails are liable to be becalmed by the waves, and therefore to suffer the ship to roll to windward; the main-topsail is then used.

LYMPH. (Lat. lympha, *water.*) The liquid contained in the lymphatics.

LYMPHA'TICS. Absorbent vessels, which carry lymph from all parts of the body, and terminate in the thoracic duct.

LYNCH LAW. The irregular and revengeful species of justice administered by the populace in some parts of the United States, is said to have been so called from a Virginian farmer of the name of Lynch, who took the law into his hands on some occasion, by chasing a thief, tying him to a tree, and flogging him with his own hands. Some observers have thought that this barbarous system was, to a certain extent, palliated by the difficulty of enforcing regular law; which Captain Marryat (*Diary in America*) attributes, with what justice we know not, to the inadequate pay of the judicial establishment in the newly settled districts, and the bad character of many of the judges, raised to the bench by electioneering politics. He instances the case of a single town in Georgia, with 3000 inhabitants, in which there were in one year fifty-nine assassinations, as a proof of the occasional utility of some irregular acts of justice on the desperadoes of such a population. But it must surely contribute to brutalize and occasion crime, far more than to repress it. One of the most signal and violent acts of popular resentment, under the show of summary justice, was the mock trial and execution of a number of professed gamblers, at Vicksburg, on the Mississippi, four years ago. Miss Martineau's work on America contains some fearful pictures of the persecution carried on, under the same pretences, against missionaries or supposed missionaries of the anti-slavery party, in the southern states. Indeed, she received a hint that she ran herself some danger of being "Lynched," if she visited them; which, however, did not affect her resolution. Lynch law may be called a democratic imitation of the old feudal Vehm-gerichte, or self-constituted tribunals in Westphalia and elsewhere, which assumed the right of controlling the violent actions of the nobles, and have been the subject of so much romantic fiction.

LYNX. A constellation of the northern hemisphere, formed by Hevelius.

LYNX. A name given to the different species of a group of the *Cats* (*Felidæ*), distinguished by short tails, and generally tufted ears. The lynxes have been long famed for their sharp sight;—a quality which, in all probability, they derived, together with their name, from Lynceus, one of the Argonauts, to whom, on their perilous expedition, his quick sight was of essential service in enabling them to steer clear of rocks and sand-banks. The lynx was consecrated to Bacchus.

LY'RA. (Lat.) The Harp: one of the forty-eight constellations of Ptolemy. It is situated in the northern hemisphere.

LY'RA. A portion of the brain, the medullary fibres of which are so arranged as to give it somewhat of the appearance of a lyre.

LYRE. A musical instrument of the greatest antiquity among the Egyptians and Greeks. Tradition attributes its invention to the accident of finding on the banks of the Nile a tortoise, whose flesh was entirely decomposed, but whose tendons, having been dried and stretched by the sun's rays, were capable, on being struck, of yielding musical sounds. Hermes, the finder of this tortoise, having made an instrument in imitation of it, is supposed thus to have been the inventor of the lyre. The Greeks attribute the invention to their Hermes (Mercury), the son of Jupiter and Maia. It is generally considered that the original Egyptian lyre was only of three strings, and that the Greek Mercury improved upon the invention; that the Muses clubbed together to add one string, Orpheus, Linus, and Thomyris adding one each, thus forming it altogether into an heptachord, or seven-stringed lyre. At a later period the lyre consisted of eleven strings, which were made of the sinews of animals; its body was hollow to increase the volume of tone; and it was played with the *plectrum* or lyre-stick of ivory or polished wood, and sometimes with the fingers like the harp. It went by the different names of lyra, phorminx, chalys, barbitos, barbiton, cithara.

LYRE BIRD, or LYRE PHEASANT. *See* MENURA.

LYRIC. *See* ODE.

LYTHRA'CEÆ. (Lythrum, one of the genera.) A natural order of Polypetalous Exogenous plants, with long, tubular, striated calyxes, in the orifice of which are inserted the petals, while the stamens grow nearly at the base. They are little known in cultivation; but some of them, belonging to the genera *Lagerstrœmia*, *Diplusodon*, *Lafoensia*, &c., are objects of striking beauty. The rosewood of the cabinetmaker is the trunk of *Physocalymna floribunda*; and the henna, employed in the toilet of oriental ladies, is obtained from *Lawsonia inermis*.

M.

M. The labial letter of the liquid series. It is susceptible of various interchanges, more especially in the Greek and Latin languages. (See *Penny Cyclo.*) In writing two M's successively the Germans frequently drop one, and replace it by a stroke over that which they retain; thus, $\bar{m}$. As an abbreviation M stands for Marcus, Manlius, Martius, and Mucius; M.A. for Magister Artium, MS. for Manuscript, and MSS. for Manuscripts. M, or, more properly, a symbol somewhat resembling it, was used by the Romans to denote 1000; and the moderns have also adopted that letter.

MAB. The name given by the English poets of the 15th and succeeding centuries to the imaginary queen of the fairies. The passage in *Romeo and Juliet*, in which her qualities and attributes are so beautifully set forth, is familiar to all.

MAC. A Scotch term, signifying son, prefixed to many surnames, as *Mac* Donald, &c. It is synonymous with *Fitz* in England, and *O* in Ireland.

MACA'CUS. A genus of Catarrhine or Old World monkeys, characterized by having a fifth tubercle on their last molars; ischial callosities and cheek pouches; comparatively short and thick limbs; a projecting muzzle, and prominent superciliary arches. They have generally a

pendant tail; but in some it is short, as in the pig-tailed baboon (*Macacus rhesus*). When they cry out, they inflate a membranous sac, which communicates with the larynx above the thyroid cartilage.

MACARO'NIC VERSE. Verse in which the words of a modern language are ludicrously distorted into Greek or Latin inflections and metre. Theophilo Folengo, who wrote under the name of Merlinus Coccaius, in Italy, in the 16th century, and calls himself the inventor of this sort of burlesque composition, informs us that its name is derived from the Italian macaroni, eatables composed of flour, cheese, and butter; and that it expresses the gross and rustic characters appropriate to its words and sentiments. *Drummond's Polemo Middinia*, a Scottish burlesque, is perhaps the best known macaronic form of our language.

MACCABEES, BOOKS OF THE. The two last books in the arrangement of the Apocryphal writings enumerated by our church. The first is a Greek translation (as is supposed) from a Chaldaic original. The second appears to be a compilation from various sources. The two books are not connected: the former comprehends the events of Jewish history for nearly 40 years, B. C. 176 to 139; the second begins about B. C. 187, and extends over about 16 years. Neither has ever been reckoned by the Jews in their catalogue of sacred writings; but they are received into the canon of Scripture by the church of Rome, with the title of *3d and 4th Chronicles*. There are two other books, commonly called *3d and 4th Maccabees*, which were never received by any church.

MACE. A word of doubtful etymology, signifying sometimes a club of metal, and sometimes a military weapon appropriated to the cavalry. About the period of Edward II. maces were generally used in England, both in battles and tournaments; and they remained so till the time of Elizabeth, when they were displaced by the pistol. Maces are still used by the Turkish cavalry. The mace, as an ensign of authority, is often borne before magistrates. By the old English writers it is used synonymously with sceptre.

MACE, the external envelop of the seed of the nutmeg, is a particular form of what botanists call *arillus*. It is aromatic, but less so than the nutmeg; and is chiefly used in cookery or in pickles, and not, like the latter, in confectionary.

MACEDO'NIANS. In Ecclesiastical History, a sect which derives its name from a bishop of Constantinople, who, in the 4th century, denied the distinct existence and Godhead of the Holy Spirit, which he conceived to be merely "a divine energy diffused throughout the universe," "while the Father and Son together constitute the one existing Deity." These opinions were condemned at the second general council held at Constantinople in 381. *See* PNEUMATOMACHI.

MACERA'TION. The steeping of substances in any cold liquor.

MACHAIRODUS. (Gr. μαχαιρα, *a sabre*, and οδους, *a tooth*.) An extinct mammal, allied to the bear.

MACHE'TES. (Gr. μαχητης, *a combatant*.) The generic name under which Cuvier has distinguished the ruffs and reeves from the sandpipers, godwits, and other allied Grallæ. The ruffs have the bill and carriage of the genus *Calidris*; but the membrane between their external toes is nearly as extensive as in *Limosa*. Our native species (*Machetes pugnax*, Cuv.) is somewhat smaller than a snipe, and celebrated for the furious combats that take place among the males in their nuptial season. At this period the head is partly covered with red papillæ; the neck is surrounded with a thick collar of feathers, which often varies in different individuals.

MA'CHIAVELISM. A name given to the system of governing which is propounded in the general writings of Machiavelli, and particularly in his treatise called *The Prince*. The term is still used in a disparaging sense, notwithstanding the different construction which has of late been given to the motives and purposes for which Machiavelli wrote his work.

MACHI'COLATED. (Fr. machicoulis.) In Gothic and castellated Architecture, a building whose parapets project beyond the faces of the walls, and are supported by arches springing from large corbels or consoles.

MACHI'NE (Gr. μαχανη), in a general sense, signifies any thing which serves to increase or regulate the effect of a given force. Machines are either *simple* or *compound*. The simple machines, otherwise called the *simple mechanical powers*, are usually reckoned six in number; namely, the *lever*, the *wheel and axle*, the *pulley*, the *wedge*, the *screw*, and the *funicular machine*. See the respective terms.

Compound machines are formed by combining two or more simple machines. They are classed under different denominations, according to forces by which they are put in motion, as *hydraulic* machines, *pneumatic* machines, *electrical* machines, &c.; or the purposes they are intended to serve, as *military* machines, *architectural* machines, &c.

Although there are no limits to the combinations and adaptations of machinery, there are certain general principles which may be applied in estimating the effects of any machine whatever. When a machine attains its state of uniform motion, the momentum of the power is equal to that of the resistance, and is the same that would be *in equilibrio* with the resistance if there were no motion at all. From this principle, and from the consideration that in all machines the work done is to be estimated not merely from the quantity of resistance which is overcome, but from the quantity overcome in a given time, we can ascertain the relation that ought to subsist between the velocity and the load or resistance in order that the effect of the machine may be a maximum. This maximum effect is produced when the two following conditions are fulfilled: 1. When the load, or resistance, is about four ninths of that which the power, when fully exerted, is just able to balance, or that which would keep the machine at rest altogether; and, 2. when the velocity of that part of the machine to which the power is applied is one third of the greatest velocity of the power. These conditions are deduced from the following empirical expression, which is adopted by Euler and other writers to represent the law of the moving power: Let P = the power applied (or weight which the power, when fully exerted, is just able to overcome); R = the resistance, or load, or weight to be overcome; c the greatest velocity, or that at which the power ceases to act; v = any other velocity: then the law of the moving power is

$$R = P\left(1 - \frac{v}{c}\right)^2.$$

The variables in this expression are R and v, and the effect is represented by the product Rv; on making which a maximum, the rules of the differential calculus give $v = \frac{1}{3}c$; whence the formula becomes $R = \frac{4}{9}P$.

From these expressions it follows, that when the moving power and the resistance are both given, if a machine be so constructed that the velocity of the part to which the power is applied is to the velocity of the part to which the resistance is applied in the ratio of 9 R to 4 P, the effect of the machine will be a maximum, or it will work to the greatest possible advantage. The above conditions apply equally to machines impelled by animal force and the agents of nature, as running water, steam, the force of gravity, &c. An animal exerts itself to the greatest advantage, or performs the greatest quantity of work in the least time, when it moves with about one third of the utmost speed with which it is capable of moving, and is loaded with four ninths of the greatest load which it is capable of putting in motion. It has been supposed in the above remarks that the friction of the parts of the machine is included in the resistance. (See Coriolis, *De l'Effet des Machines*; Navier, *Leçons sur l'Application de la Mécanique*; Belidor, *Architecture Hydraulique*; *Gregory's Mechanics*; *Moseley's Mechanics applied to the Arts*, &c.)

MACHI'NERY. A general term by which the works of the complex machines are designated.

MA'CIGNO. (Ital.) A hard silicious sandstone.

MA'CLE. A mineral; called also *chiastolite*. It forms prismatic crystals, white externally and grey within, which are found embedded in clay-slate. Its principal component parts are silica and alumina, with a little oxide of iron.

MACLU'REITE. A mineral named after Dr. Maclure, from New York and New Jersey. It occurs in roundish embedded masses, imperfectly crystalline. It is a silicate of magnesia, with traces of potash, oxide of iron, and fluorine.

MACMILLANITES. A religious sect in Scotland, the successors and representatives of the Covenanters in the 17th century, and more recently denominated the Reformed Presbytery. On the first settlement of presbytery as the established church of Scotland at the Revolution in 1688, a small body of the people, the remnant of the Covenanters, condemned the principles on which that act was founded as Erastian. They insisted not only that the church, though endowed by the state, should be entirely independent of civil authority, and uncontrollable and supreme in itself, but that the revolution government should not be recognized, inasmuch as it was not founded on the Solemn League and Covenant, and did not restore presbytery as it had obtained during what they called the "Second Reformation," or between 1638 and 1649, at the death of Charles I. Though reduced to a very small number at the era of the Revolution, and deserted by their pastors, who, in 1689, gave in their accession to the judicatories of the established church, they maintained their principles with unshaken firmness, and would accept of no conditions of which these were not the basis. They also continued zealously to maintain those praying societies (hence they were sometimes called Society people) which they had formed in the time of Charles II., when deprived of religious ordinances from the paucity of clergymen. A regular correspondence between these various fraternities was maintained, in order to ascertain the

state of matters throughout the body at large, and to cultivate a closer acquaintance with each other.

Thus they remained without a pastor for sixteen years; and as they were a small, so they were generally regarded as a fanatical and illiberal sect, enemies equally to the ecclesiastical and civil authorities. Meanwhile, Mr. John M'Millan, who had been ordained parochial minister of Balmaghie, in the stewartry of Kirkcudbright, in 1701 adopted and publicly avowed their principles; and was, in consequence, deposed in 1704 from the office of the ministry. He did not, however, renounce his ministerial character; but continued to officiate both among his former people, who almost to a man adhered to him, and others who favoured his views. In 1706, having received a unanimous call from the scattered societies to be their minister, he accepted the invitation; and in a short time he was joined by Mr. John M'Neil, a licentiate of the established church, who, like himself, had been deprived of all connection with that church. The high veneration which Mr. M'Millan and Mr. M'Neil entertained for presbyterian government, prevented any attempt being made to obtain ordination for the latter in an irregular way. Neither would they compromise their principles to gain the co-operation of other ministers who, like themselves, but for somewhat different opinions, had been expelled from the establishment. They renewed the Covenant in 1712, and never ceased to bear public testimony against what they regarded the defections and corruptions of the church of Scotland.

On the death of Mr. M'Neil, which took place not long afterwards, Mr. M'Millan was joined by the Rev. Thomas Nairn, who had been driven from the church, and had for some time been connected with the Secession. The prospects of the *M'Millanites*, as this sect had long been called in honour of their eminent leader, now began to brighten. Their two clergymen and some lay elders (formerly ordained) constituted a presbytery, in 1743, at Braehead, near Carnwath, Lanarkshire, and gave their body the name of the Reformed Presbytery, — a designation which has superseded, in a great measure, that of M'Millanites. They are also called Mountain or Hill people; because, having at first no chapels, they conducted public worship, in imitation of their persecuted ancestors in the reigns of Charles II. and his brother, in the open air, generally on the side of a hill.

From the time they were constituted into a presbytery, their number has gradually but slowly increased. In 1809 they had sixteen congregations; but their highest ecclesiastical court was a presbytery. They now form a synod, consisting of six presbyteries; the number of congregations being thirty-five. In the days of persecution, some of their adherents took refuge in the north of Ireland; and the M'Millanites there form four presbyteries, embracing twenty-one congregations. The sect prevails also in the United States to the extent of eight or ten congregations. Some of their congregations in Scotland are very small, and none of them are large. They have a professor of divinity belonging to their own body. In doctrine they profess the highest Calvinism; and may be characterized as the strictest sect of Presbyterians. They still hold substantially the same sentiments as the alleged Erastianism of the established church, or what they regard as her unscriptural subjection to the civil power. Some of their extreme opinions, however, on the subjects of the covenant and presbytery have of late been somewhat modified. They generally, if not universally, use public prayers for the sovereign and for civil magistrates; an act which they from conscience avoided for about a century after their organization under Mr. M'Millan. Wherever their numbers are sufficiently large, they have built chapels; and public worship, in any circumstances, rarely takes place out of doors. They have not thought it expedient to renew the Covenant since 1745. In short, they have become a comparatively liberal and enlightened sect of Christians, and are eminently characterized by piety and moral strictness. (See *Adam's Religious World Displayed*, vol. iii. 157—169.; *The Testimony of the Reformed Presbyterian Church*, Paisley, 1837; *Historical Part of the Testimony*, Glasgow, 1839; *A short Acc. of the Old Presbyterian Dissenters*, Glasgow, 1824; *Acts of Gen. Assembly apud Ann.* 1704, 1708, 1715: also the articles CAMERONIANS and COVENANTERS in this work.)

MACRODA'CTYLI. (Gr. μακρος, *long*; δακτυλος, *a finger*.) A tribe of wading birds, comprehending those in which the toes are remarkable for their extreme length; as the jacanas.

MA'CROPUS. (Gr. μακρος, *long*; πους, *foot*.) The generic name of the kangaroo; also applied to a genus of beetles.

MACROU'RANS, *Macroura*. (Gr. μακρος, *long*, and ουρα, *a tail*.) A section of Decapod Crustaceans, including all those which have the tail, or post abdomen, as long or longer than the body.

MA'CULÆ. (Lat. *spots*.) Dark spots on the surfaces of the sun and moon, and on some of the planets. The solar spots are very variable as to form and continuance. They were first observed by Galileo in Italy, and Harriot in England, soon after the invention of the telescope, and unknown to each other. The spots on the moon are permanent, and are caused by the shadows of its mountains, and the unequally reflecting materials of which parts of it are composed. The planets have some permanent maculæ, as the belts of Jupiter; and some variable, especially Mars and Venus, and frequently, also, Jupiter. These maculæ have led to many fanciful conjectures respecting the constitution and atmospheres of the bodies of the solar system. *See* SUN, MOON.

MA'DDER. The prepared root of the *Rubia tinctorum*. It is extensively used as a red dye stuff; its infusion is of a dirty red colour; but it is rendered bright and permanent by an aluminous mordant. Its colouring principle has been termed *alizarine*.

MA'DIA. (Gr. μαδος, *bald*.) A genus of Composite plants, inhabiting South America and California, and important because of the utility of the fruit as a source of vegetable oil. From some German reports it appears that it is the most productive of all oil plants.

MADO'NNA. (Engl. *my lady*.) An Italian term applied to the Virgin Mary. Hence pictures of the Italian school representing the Virgin are generally designated as "Madonnas."

MA'DREPO'RA. (A hybrid compound of the French madré, *spotted*, and the Latin porus, *a pore*.) The word appears to have been first used by Imperati to designate a genus of Lithophytes, in which the calcareous axis has its whole surface beset with small lamellate and stellate depressions.

The genus was adopted by Linnæus, who placed it among his *Vermes Zoophyta*, and characterized it as follows: — "*Animal* resembling a medusa; *coral* with lamellate star-shaped cavities." It is scarcely necessary to observe that the animal, especially in the larger madrepores, as the *Fungia*, most closely resembles the *Actinia* in its general organization. Cuvier places the madrepores in the tribe *Lithophyta*, of the family of *Polypi corticati*. The Lithophytes having the common character of the Linnæan genus are now subdivided into the genera *Fungia*, Lam.; *Turbinolia*, Lam.; *Cyclolythus*, Lam.; *Caryophyllæa*, Lam.; *Oculina*, Lam.; *Pœcillopora*, Lam.; *Serialopora*, Lam.; *Astrea*, *Explanaria*, *Porites*, *Meandrina*, Cuv.; *Pavonia*, Cuv.; *Hydrophora*, Fischer; *Agaricina*, Cuv.; *Sarcinula*, Lam.; *Stylina*, Cuv.; and *Madrepora* proper.

MA'DREPORITE. A species of columnar carbonate of lime found in Norway and Greenland.

MA'DRIER. In Military Engineering, a thick plank covered with plates of iron, and having a cavity sufficient to receive the mouth of a petard, with which it is applied against a gate or any other obstacle intended to be broken down. Also, the flat beams laid in the bottom of a moat or ditch to support the wall. There are also madriers lined with tin and covered with earth, to form roofs over certain portions of military works, in order to afford protection against fires in lodgments, &c.

MA'DRIGAL. One of the lesser kind of poems, usually consisting of fewer verses than the sonnet or roundelay. In its composition the fancy and convenience of the poet are not subjected to very strict rules, rhymes and verses of different species being often intermixed. The subjects are mostly of a tender and gallant nature; the character often quaint, the expressions marked with great simplicity. Sometimes, however, a loftier and sublimer train of thought finds its way into these compositions, especially among those of the English school, as in the following celebrated specimen, set to music, and perhaps written, by Orlando Gibbons, in 1612: —

> Oh! that the learned poets of this time,
> Who in a lovesick line so well can speak,
> Would not consume good wit in hateful rhyme,
> But with deep care some better subject find;
> For if their music please in earthly things,
> How would it sound if strung with heav'nly strings!

Of a lighter and more regular sort, the following may serve for a specimen: —

> When Thoralis delights to walk,
> The fairies do attend her;
> They sweetly sing and sweetly talk,
> And sweetly do commend her.
> The satyrs leap and dance around,
> And make their congés to the ground;
> And evermore their song is this,
> "Long may'st thou live, fair Thoralis!"

Grassineau, in his *Musical Dictionary*, describes the madrigal as "a little piece of poetry, the verses whereof were free and easy, usually unequal: it borders on a sonnet and an epigram; but has not the briskness of the one, nor the poignancy of the other."

It is extraordinary that the etymology of this word, though introduced but little more than three centuries ago, is now altogether lost. We subjoin the conjectures that have been raised upon it. Rengifo (*Arte Poetica*) says that it is corrupted from the word mandrial, *a sheepfold*. Cardinal Bembo seems to think with the last-named

author, and defines it as a pastoral love-song; adding, moreover, that it is of Provençal origin. Huet brings it from *Martegaux*, the name of a people of Provence. "Ces martegalles et madrigaux," he observes, "ont pris leur noms des Martegaux, peuple Montagnards de Provence: de mesme que les Gavots, peuple Montagnards du pays de Gass, ont donné le nom à celle que nous appellons gavotte." (*Traité des Romans*, p. 124.) Covarruvias (*Trésor de la Langue Castellan*) derives it from *mandra*. So that there is much testimony in favour of its pastoral origin. But the most curious, perhaps, of all the etymologies is that of Ferrari, in his *Origine de la Langue Italienne*, who derives the word from the Spanish verb madrugar, *to rise in the morning;* which Menage in his *Dict. Ety.* says is naught. This last-named author throws out a suggestion that it may have had its origin in a town called Madrigal (of which name, indeed, there are two in Old Castile), in Spain; as from Vallée de Vire has been formed the word Vaudeville (p. 464.). Others, supposing that the earliest specimens of this sort of poetry were addressed to the Virgin (*alla madre*), have thence derived madrialle and madrigale; and go on to say that having afterwards been applied to poems of love and gallantry, the original meaning was lost. The words of a very large proportion of the madrigals of the sixteenth century, a period when they were most in favour, are certainly compositions indicating addresses to the mother of love and gallantry (*alla madre galante*) rather than to the Virgin. At this period, moreover, the composers called their motels *madrigali spirituali*. We regret that we cannot guide the reader with any certainty upon this subject, in which we must leave him to a choice among the etymologies here set down, or to find one of his own that he may think more germane to the matter.

We will now endeavour to define this word in a musical sense; and we do not think we can better accomplish that object than in the quaint language of old Charles Butler (*Principles of Music*, London, 1636). He says, "The madrigal is a chromatic mode in discant, whose notes do often exceed the number of the syllables of the ditty, sometimes in duple, sometimes in triple proportion, with quick and sweet reports and repeats, and all pleasing varieties of art, in four, five, or six parts; having in one or more of them one or more rests, especially in the beginning, to bring in the points begun in another part." Choron calls it a species of composition resembling the fugue, but the style of which, being less dry, is susceptible of every kind of expression. The simple madrigal is for voices only; the accompanied madrigal, as its name imports, is with an accompaniment of one or more instruments, mostly the organ. To Arcadelt, a Flemish composer, has, but without foundation, been attributed the honour of composing the first madrigals. They, however exist by more ancient composers, even by those of the Flemish school; and to our readers who are at all conversant with the subject, the name of Adrian Willaert will doubtless occur as one of the composers alluded to. The fact is, that simple madrigals appeared about the beginning of the 16th century, during which, and the whole of that following, the style was particularly cultivated and encouraged, and may be considered to have now passed away, unless we are allowed to consider the English glee an offset from it. The first madrigals were in a style of music very much resembling that of the church; but they afterwards assumed a character peculiar to themselves, which is strikingly exemplified in those of Luca Marenzio (soon after the time that Palestrina flourished), and after him in the works of Gesualdo, the Prince of Venosa, Monteverde, and Mazocchi. It is in their madrigals that the restraints which laboured counterpoint imposed were abandoned, to make way for imitations, canons, and fugues. The style was indeed that of the age, but the subjects were free; and the tender and impassioned poetry adopted was well expressed in the affections of the harmonies employed. The original character gradually became more free, and was carried to its utmost limit in the compositions of the celebrated Alessanbro Scarlatti. In England, during the reign of Elizabeth, the composition of the madrigal attained a very high degree of excellence, perhaps the highest. Our composers were in no respect inferior to those of Italy and the Netherlands. It is hardly necessary to observe that among them are to be found the names of Orlando, Gibbons, Dowland, Wilbye, Ward, Bennett, and Morley.

MAESTO'SO. (Ital.) In Music, a direction to the performer that the music to which the word is prefixed is to be performed slowly and with grandeur.

MAGAZINE. (Fr. magazin.) A receptacle for military stores, but especially for gunpowder, in a fortress.

Magazine. An apartment below, in the after part of the ship, in which the powder is kept. As lights are not allowed to be burnt here, the light is received from another apartment, called the light-room.

Magazine. In Literature, the general designation for the periodical literature of a country, exclusive of the newspaper and review. The peculiar province of the two latter seems to be to communicate information — the one on politics and passing events, the other on literary and scientific subjects; while that of the magazine is of a more miscellaneous character, embracing all the features of the newspaper and review, but at the same time containing, in the form of tales, sketches, and poetry, &c., a great variety of what may be peculiarly termed *original* matter, the introduction of which would be foreign to the purposes of the others. The earliest publication of this kind in England was the *Gentleman's Magazine*, which still exists. It appeared in 1731; and the success which so deservedly followed its establishment immediately called into the field a host of competitors, which have so increased in number and variety as to form an era in literary history. See Periodicals, Review.

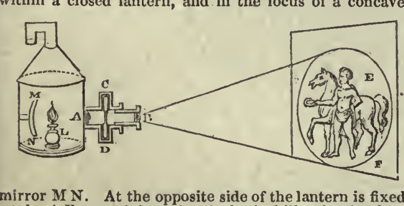
MAGELLA'NIC CLOUDS. Three nebulæ in the southern hemisphere, first recorded by the navigator Magellan, and named after him; two of them about 12° or 13° from the south pole, and the third more distant. Whether they be resolvable into stars by means of the larger telescopes, has not been yet ascertained; but, from their distinctness as nebulæ, they probably are.

MA'GIANS. The caste of priests (hereditary) among the Persians and Medians are so termed by ancient Greek historians. The name has been derived by modern orientalists from *mog* or *mag*, signifying priest in the Pehlevi language. Zoroaster is designated as the great reformer of the order; but the history and the very existence of that celebrated character are enveloped in complete obscurity. He is generally supposed to have lived at no long period before the age of Cyrus. The most remarkable feature of his doctrine consisted in the two principles of Good and Evil (Oromasdes and Arimanes), who were held to divide the dominion of the world, in alternate periods, during its whole predestined duration of 12,000 years. The books termed the *Zendavesta*, brought to Europe in the last century by Anquetil du Perron, are supposed by some to contain the essential doctrines of this religion; but their authenticity has been the subject of much discussion. The fire-worshippers of Persia and India still hold them in reverence. (*See* Zendavesta, Guebres.) Our amplest resources for the study of the religion and character of the ancient magi are to be found in the learned researches of Anquetil. (See especially *Mémoires de l'Acad. des Inscriptions*, vol. xxxiv.)

MA'GIC. (Lat. ars magica, *the art of the Magi;* because those Persian philosophers were ranked by the Romans among the highest professors of supernatural powers, through intercourse with the genii or intelligences with which their universe was peopled.) Common as the superstitious belief in the possession of such powers has been among all nations hitherto discovered on the globe, the Romans were, perhaps, the most superstitious in this and other respects of all people. No American tribe has a more implicit faith in its rude "medicines" or "mysteries," than this great and civilised people had in its auguries and divinations; and it is a remarkable feature in their character, that while their religion prescribed these rites, the popular imagination was always searching after fresh excitement from others, which were not only unauthorized, but condemned by their laws, — the practices of the Thessalian witches, the magi, the sorcerers of Egypt and Phrygia, and the numberless other foreign nations with which their dominion brought them in contact. Against these the emperors were continually renewing their ineffectual edicts; and it seems to have been mainly from this circumstance that the idea of magic, as a black and forbidden art, became rooted in the minds of the people of modern Europe. For the northern conquerors held such supernatural power in high respect; and in the East, the favourite land of sorcery and magic, the professors have from time immemorial been regarded rather as venerable than as hateful. As to ancient magic, see *Mém. de l'Acad. des Inscr.* vol. xxxix. Hence, if any systematic account can be attempted of matters which have their foundation in the strange caprices of popular credulity, it may be thought that, in the superstition of the middle ages, *white* magic or *celestial* magic, according to Cornelius Agrippa's division, originated in the North or East; *superstitious* or *diabolical* magic from Roman notions engrafted on Christianity; while *natural* magic arose merely from the disposition among the scientific of those days to take advantage of the vulgar propensity to attribute every thing extraordinary to supernatural causes. It is to be observed that among the crusaders, and other Christian warriors of the middle ages, magic was regarded as a peculiar ally of the eastern and northern infidels with whom they were in contact. The inhospitable North was peopled by their imagination with enchanted castles and spectral illusions (see *Scott's Dæmonology and Witchcraft*, letter v.); and Froissart gives a most picturesque account of the spells which were resorted to by Mahometan warriors in their conflicts with the soldiers of the cross. In the romances founded on these historical encounters there are usually a good magician or witch (not the degraded witch of vulgar superstition, but the French fée, Italian fata) enlisted in the Christian party; evil necromancers in that of the infidels. Thus,

in *Ariosto*, Malagigi and Melissa aid the one side, and Atlas the other. The notion of *white witches*, or beneficent wizards, was assiduously kept up by those impostors who wished to profit by the public credulity, and yet avoid the penalties awarded by the church; and in the church itself there was a contest continually maintained, whether magic, practised through laborious research and study of the celestial influences or intermediate spirits, was lawful. But the public opinion always inclined the other way; and the magicians of highest pretensions were always in danger of being classed with the hated necromancers who derived their power from compact with the devil. Among the earliest fables respecting the higher order of European magicians is that of Virgil, the Latin poet, turned into a wizard by popular belief, which dates as high as the 11th or 12th century. Robert of Lincoln (Grossetête), Michael Scot, Albertus Magnus, and the famous Roger Bacon, all lived in the 13th. Of these the first was a church reformer, who seems to have lain under the imputation of magic merely on account of the displeasure with which he was regarded by the orthodox. Michael Scot is almost wholly a traditional personage; that is, his real history is scarcely known: the European reputation which he had achieved as a wizard is proved by the high mention of him in the *Inferno* of Dante, who condemns all magicians indiscriminately to eternal punishment. It is difficult to say that Roger Bacon ever gave any cause by pretensions of his own, like so many other eminent natural philosophers of early time, to those charges of magic to which his high genius subjected him. Perhaps Sir F. Palgrave, in his amusing fiction (*The Merchant and Friar*), is not far wrong in representing him as partly dazzled by an inability to comprehend the real extent of those extraordinary discoveries which were opening upon him, and partly owing his magical reputation to the impostures practised by his servants in his name. Albertus Magnus, a Dominican, and a celebrated magician in his time, lies more justly open to the charge of quackery. It seems to have been after this time, about the 14th century, that magic rose for a season into high repute as a lawful art, and sovereigns had professed magicians and astrologers attached to them. The extraordinary tales related of some of these point evidently to results effected by means of legerdemain: the feats of Ziito, sorcerer to Wenceslas, king of Bohemia (Godwin, *Lives of the Necromancers*, p. 273.), are exactly a counterpart of what Tavernier saw at the court of the Great Mogul. The higher order of magicians maintained their pretensions with difficulty after the revival of letters. Yet the three most famous of all belong to the commencement of that era: Doctor Faustus (if that personage be not altogether traditional), Cornelius Agrippa, and Paracelsus. It will, however, be evident, to any one who reads their history, that the belief in *celestial* magic was with difficulty maintained in their days, while that in *necromancy* and *witchcraft* was becoming more prevalent than ever. There is a good deal of mystery about the character of the famous Dr. Dee; and it does not appear distinctly how far he pretended to those powers which are ascribed to him in that dreary work entitled, *A True Relation of what passed between Dr. Dee and some Spirits*, published by Meric Casaubon, in 1659. In 1634, the French curate, Urbain Grandier, was burnt for sorcery at Loudun; in 1640, the pretender, Dr. Lamb, was murdered by the London mob: and these are nearly the latest instances of distinguished magicians, while the degraded belief in witchcraft lasted much longer. As to *natural magic*, or the production of singular phenomena by natural means, see *Brewster's Letters on Nat. Magic*; *Quart. Rev.* vols. xlviii. lix.

MAGIC LANTERN. An optical instrument, by means of which small figures, painted with transparent varnish on slides of glass, are represented on a wall or screen considerably magnified. It is generally used as a toy, and affords amusement from the grotesque character of the figures; but is also employed to enlarge the diagrams employed in astronomical lectures, so as to be seen by an audience: for which purpose it is well adapted, both by its portability and the small cost of the whole apparatus. The principle of its construction is very simple. A lamp L, with a powerful Argand burner, is placed within a closed lantern, and in the focus of a concave



mirror M N. At the opposite side of the lantern is fixed a tube A B, containing a hemispherical illuminating lens A, and a convex lens B; and between A and B is a slit C D, through which the sliders of painted glass are introduced. In this manner the picture is placed in the axis of the tube, and strongly illuminated, in consequence of the light being concentrated upon it by the mirror. The picture being also in one of the conjugate foci of the lens B, an enlarged image of it is formed upon a wall or screen E F at some distance behind. The tube A B is made to pull out, so that the distance of the lens B from the slider can be increased or diminished at pleasure, and consequently an image formed of any size within moderate limits. The magic lantern was invented by Athanasius Kircher.

MA'GIC SQUARE. A term used to denote a series of numbers in arithmetical progression, arranged in the equal cells of a square in such a manner that the vertical, horizontal, and diagonal columns give the same sum. For example, let the first sixteen numbers be arranged as in the annexed table, and a magic square will be produced; for the numbers in each vertical column, in each horizontal column, and in the two diagonal columns, being added together, give the same sum, namely, 34. This is, however, only one of a great number of ways in which the same numbers may be arranged so as to fulfil the conditions. Frenicle (*Divers Ouvrages*, Paris, 1693) has shown that there are 878 such arrangements.

Emanuel Moscopolus, a Greek author of the 14th or 15th century, is the first who is known to have treated of magic squares, and to have given rules for their construction. The principal authors who have written on the subject are Stifels, Leibnitz, Bachet, Poignard, Lahire, Ozanam, Franklin, &c. For the history of the subject, see *Montucla*, vol. i. p. 346., or *Hutton's Dictionary*; and for the methods of constructing them, *Ozanam's* or *Hutton's Mathematical Recreations*.

MAGILP. When linseed oil and mastic varnish are mixed together they produce a gelatinous compound known under the above name, and used by artists as a vehicle for colours.

MA'GILUS. A name given by Montfort to a genus of Tubulibranchiate Gastropods in the system of Cuvier, chiefly remarkable for the form, length, and solidity of their shell. The modifications of this dermal production are due in the present instance, in great measure, to the accidental circumstances of the locality in which the growth of the individual proceeds. The young *Magilus* commences its career in a bed of lithophytous coral, and during the early and rapid stages of its development, secretes its calcareous covering in the ordinary form of a spiral univalve; but soon the growth of the surrounding madrepore surpasses its own, and it is compelled to bring its oral and respiratory orifices, by the most direct route, to the level of the surrounding coral. While this change of place is being effected the mollusk continues to secrete fresh layers of shell coextensive with its own advance, and to fill up the deserted part of the shell with a solid deposit of a dense, semivitreous, and subtransparent carbonate of lime, and finally produces an elongated, slightly wavy, tubular shell, with the apex sculptured in the form of a spiral univalve, and the opposite end excavated for a certain depth for the lodgment of the animal. The tube is characterized by being longitudinally carinated.

MAGI'STER (contracted Mister or Mr.). An appellation given, in the middle ages, to those persons who had attained some degree of literary or scientific eminence, — in scientiâ aliquâ præsertim literariâ. It was equivalent to the modern title of doctor.

MAGISTER EQUITUM. An officer among the Romans subordinate to the dictator, by whom he was usually elected. *See* DICTATOR.

MA'GISTERY. The old chemists generally applied this term to *precipitates* produced by the dilution of certain solutions with water: such as magistery of *bismuth*, which is an insoluble subnitrate, obtained by pouring nitrate of bismuth into water.

MA'GISTRATE. (Lat.) A general designation of those public officers to whom the executive power of the law is committed, either wholly or in part. It is almost impracticable to give any definition of this term so comprehensive as to include within it all the offices, both in ancient and modern times, to which this appellation has been given. Under the various heads, the reader will find a notice of the principal magistrates of all ages and countries.

MAGMA. (Gr. μασσω, *I blend together.*) A thick ointment or confection.

MA'GNA CHARTA. *See* CHARTA, MAGNA.

MA'GNATES. In Hungary at this day, and formerly also in Poland, the title of the noble estate in the national representation. (*See* STATES.) The Hungarian magnates are divided into greater and lesser; certain high state officers belonging to the first class, the counts and

barons of the kingdom to the second. The title is of Latin derivation.

MAGNE'SIA. A white, tasteless, earthy substance, usually obtained by exposing its hydrated carbonate to a red heat. Its specific gravity is 2·3. It is almost insoluble; but when moistened and put upon turmeric paper it reddens it: this sometimes depends upon a trace of lime. It is an oxide of a brilliant white metal, which has been called *magnesium*, and which may be obtained by heating chloride of magnesium with potassium: they act intensely upon each other, chloride of potassium is formed, and magnesium separates: it may be washed with water and dried. Heated to redness in the air, it burns with great brilliancy into magnesia; 12 parts of the metal combining with 8 of oxygen to form 20 of magnesia. In commerce, pure magnesia is generally distinguished by the term *calcined magnesia*; and the hydrated carbonate of magnesia, obtained by precipitating a solution of sulphate of magnesia by carbonate of soda and washing and drying the precipitate, goes by the name of *magnesia*, or *magnesia alba*. The chief use of magnesia and its carbonate is in medicine. *Sulphate of magnesia* is obtained by evaporating the residue of sea-water after the common salt has been separated, or by adding sulphuric acid to *bittern* and evaporating, so as to obtain the resulting sulphate of magnesia. This salt is also obtained by the action of dilute sulphuric acid on magnesian limestone, and it is not uncommon in mineral waters: it was formerly procured from certain springs near Epsom, in Surrey, and was hence termed *Epsom salt*. It crystallizes in four-sided prisms with dihedral summits. Its crystals are soluble in their weight of water at 60°, and in three fourths their weight at 212°. They melt when heated, and gradually lose their water of crystallization. They consist of 20 magnesia, 40 sulphuric acid, and 63 water. This salt is a useful purgative in medicine, and is the chief source of the other forms of magnesia. All the magnesian salts have a peculiar bitterish flavour. Magnesia is found native in the state of hydrate and carbonate; it exists as a component part of several minerals, and many of them are soft or soapy to the touch.

MAGNE'SIAN LIMESTONE. An extensive series of beds lying in geological position immediately above the coal measures; so called because the *limestone*, which is the principal member of the series, contains *magnesia*. *See* GEOLOGY.

MAGNESITE. Native magnesia.

MAGNESIUM. The metallic base of magnesia; which see.

MAGNE'TIC COMPASSES. *See* COMPASS.

MAGNETIC COMPENSATOR. A contrivance devised by Mr. Barlow for eliminating the influence of a ship's guns and other iron in deranging the bearings of the compass. It consists of a plate or combination of plates of iron placed near the binnacle, so as to counteract, by an equal and opposite attraction, that of the rest of the iron on board the vessel. Mr. Airy (*Phil. Trans.* 1839) has investigated the law of disturbance in the case of vessels built of iron, and shown that the disturbing force consists of a very large force of permanent magnetism in the rolled and hardened plates employed in the construction of the vessel, and a very small force of induced magnetism, which changes with the place of the ship, or rather with the varying circumstances of terrestrial magnetism by which it is produced. Mr. Airy has given a set of practical rules for correcting the disturbing forces by means of two powerful magnets placed at right angles to each other below the compass, and a box of small iron chain, which is used instead of Barlow's correcting plate.

MA'GNET, NATURAL. One of the numerous oxides of iron; possessed, however, of properties peculiar to itself, if we except the metals nickel and cobalt, which possess it also in a very slight degree. The magnet consists chiefly of two oxides, together with a small portion of quartz and alumine. Its colour varies in different specimens, according to minute differences in the ratios of the two oxides, and the nature of the foreign substances with which they are found united; but it is usually of a dark-grey hue, and has a dull metallic lustre. It is found in considerable masses in the iron mines of Sweden and Norway; in the Isle of Elba; in different parts of Arabia, China, Siam, and the Philippine Islands. Small magnets are also occasionally, though rarely, met with among the iron ores of this country. The properties are,—

1. It attracts iron in all its states except the oxides.

2. If formed into a bar, and suspended freely by a hair, or on a pivot passing through its centre, it will turn itself round, and, after a few pendulous vibrations, settle into some one position; which it will retain if left undisturbed, or if disturbed will, after a few similar vibrations, return to it again as before.

3. By rubbing on a bar of steel it will give the bar the same properties; and a bar of soft iron will, while contiguous to it, even when not touched by it, obtain the same properties, which, however, the iron does not, like the steel, retain upon removal.

4. The position of rest is different at different places, and different at the same place at distant periods of time.

A great number of amusing toys have been formed of this substance, and the phenomena are often at first sight very surprising; but its application to the purposes of navigation renders it one of the most important discoveries ever made. The earlier navigators believed that it pointed always to the north pole of the world; and that therefore by means of it they could always at once tell the direction of their meridian, and consequently in what *direction* they were sailing. It was hence called the *loadstone*, or *leading stone*.

The employment of the loadstone itself for the purposes of navigation has long been laid aside; as *artificial magnets* can be constructed having a much greater intensity of directive power. *See* MAGNETISM.

MAGNETIC NEEDLE. An instrument suspended by its centre, and magnetized, which shows the direction of the resultant of the magnetic forces at the place of observation. *See* COMPASS and DIPPING NEEDLE.

MAGNETIC PYRITES. Native black sulphuret of iron: it attracts the magnetic needle.

MA'GNETISM. The science which investigates the phenomena presented by natural and artificial magnets, and the laws by which they are connected. The following brief explanation of it under both aspects will serve to render the subject generally intelligible; but it is impossible to give more than the essential phenomena and the general laws, without descending to the detail of particular cases. For further information reference may be made to the excellent compendium of Dr. Roget, in the *Library of Useful Knowledge*; to *Mr. Barlow's Magnetic Attractions* (2d ed.), and *Treatise on Magnetism* in the *Encyclopædia Metropolitana*; *Sir D. Brewster's Treatise on Magnetism* in the *Encyc. Britannica*; Gilbert, *De Magnete*, 1600, folio; *Robison's Mechanical Philosophy*; Biot, *Traité de Physique*, tom. iii.; Pouillet, *Elémens de Physique*; Becquerel, *Traité d'Electricité et du Magnétisme*; and various papers in the *Transactions of the Royal Society of London and Edinburgh*. To the work of Dr. Roget we have been under great obligations in drawing up the present abstract.

Phenomena of Magnetism. — Phenomenon 1. If a nicely balanced piece of steel be suspended from its middle by a piece of untwisted silk, or allowed to rest upon a pivot, free to turn in all directions, both horizontally and vertically; and if it be then magnetized by any of the methods hereafter described, it will turn itself into one particular position, and if disturbed by any means it will return invariably to the same as its position of repose. The horizontal angle which it makes with the meridian is called its *variation*, or its *declination*; and the vertical angle which it makes with the horizon its *dip* or *inclination*.

Phenomenon 2. Both these angles (dip and variation) continually change at the same place of observation; sometimes the latter very rapidly; the former, so far as has yet been observed, very slowly at all places. Thus, about 1659, at London, the needle pointed in the direction of the geographical meridian: before that time it had pointed eastward of it; but from that time till about 1818 it had continually made an angle more and more westward, till it arrived at a variation of 24½°. Since then its motion has again been retrograde, and it is now little more than 23¾° west. (*See* COMPASS.) The dip has also undergone similar variations: at London in 1773 it was 72° 19′, and in 1830 it was 69° 38′.

Phenomenon 3. The observation of navigators shows that there is a curve line on the surface of the earth, at every point of which the needle will take a horizontal position. This is called the *magnetic equator*. It seems to cross the geographical equator in four points; and its form and position are also undergoing continual changes. M. Morlet and M. Hansteen have investigated this subject with great care; and the former thinks it changes only its position, not its form, which is contrary to what theory would lead us to expect.

The lines at which the dip is the same number of degrees are called *magnetic parallels* of that degree, or more properly *lines of equal dip*; and the points at which the needle takes a vertical position the *poles*, *poles of convergency*, or more properly *poles of verticity*. The points at which the variation is any given number of degrees constitute lines on the earth's surface, called *lines of equal variation*, or (after Dr. Halley, who made a considerable number of observations on them) *Halleyan lines*; and the vertical circle whose plane coincides with the needle in its free position at any place is called, though improperly, the *magnetic meridian* of that place.

Phenomenon 4. If the same needle, whether compelled by its form or by loading one end of it with a weight sliding as an armature to keep a horizontal position, or free to take its own proper dip at each place successively, be made to vibrate by being drawn from its natural position, and then liberated, it will perform its vibrations more rapidly in some places than in others, and in the same place at different distant periods. Its

places of most rapid horizontal vibration are not to be considered as those at which the most rapid vibrations of the freely suspended needle take place. Hansteen has very laboriously investigated, from observations made by himself and others, the curves where the horizontal vibrations are the same; and he thinks there are four poles at which it is more rapid than at any points immediately near them. But the rate of vibration of the free needle has as yet been observed at very few places with sufficient care to justify any general conclusion respecting such poles of vibration. The velocity of vibration indicates the variation of the *intensity* of the vibrating force, the needle itself acting as a pendulum.

Phenomenon 5. The intensity itself varies at different times of the day, and under all variations of temperature in the surrounding medium; the place of observation being the same. This was first observed more than a century ago; but its laws and circumstances have been only recently investigated by Mr. Christie, and subsequently by M. Küpffer. (See *Phil. Trans.* 1824; *Annales de Chimie*, 1826; and *Mr. Christie's Report on the Present State of our Knowledge respecting Terrestrial Magnetism*, in the *Reports of the British Association.*) The variation also undergoes similar changes, and it is believed the dip also; but this has not been well established by observation.

It is the opinion of Mr. Christie, Sir David Brewster, and others, that the places on the earth where the temperature is lowest are precisely those where the magnetic intensity is the greatest, accordant with what Mr. Christie's experiments on the influence of temperature would lead us to expect; but till we have more certain knowledge of the state of magnetic intensity at those places we cannot affirm this to be the case, probable as it may seem to be.

In the following phenomena the place is supposed to be chosen, and the dip, variation, and intensity to be fixed thereby. It may be any place whatever on the surface of the earth. We shall suppose it to be London (and there is comparatively little variation of these elements in the British Isles). The point of the needle which dips below the horizon, and points to the westward of the meridian, is called the *north pole* of the needle, and the elevated one the *south pole*. When the horizontal needle is used, the same terms apply; the end which varies westward being the north pole, and the other the south pole.

Phenomenon 6. If either pole of a magnet be brought near any small piece of soft unmagnetized iron, it will be found to attract it. Iron filings, for instance, are immediately collected together when a magnet is placed among them; and they adhere to it when lifted up, and more especially about the poles of the magnet, in thick clusters. About the intermediate parts the number that adhere is much less than nearer the ends; and in every magnet there is a part to which the filings have no tendency to adhere at all. It thus appears that the magnetic forces, whatever be their nature, are situated near the extremities of the magnet; but it has been long questioned whether they be resident in two isolated points, or diffused for considerable distances round those points, but in a state of less intensity as they recede from those centres.

Phenomenon 7. When, instead of fragments of iron, we substitute a rectangular or cylindrical bar of soft unmagnetized iron, the magnet and the iron will be mutually attracted towards each other. The best mode of exhibiting this is to suspend them by threads of untwisted silk at the appropriate distances, as the friction they would undergo in sliding on a table is thus removed. It will be found that the ends which are nearest to each other will tend to coalesce; and that the other ends will tend to coalesce or recede, according as the remote end of the iron happens to be situated with respect to the body of the magnet.

If another iron body be brought near the former in this state of the apparatus, the first iron will be found to be converted into a *temporary* magnet also; and, in like manner, the second piece of iron may be proved to have become also a temporary magnet; and then the third, and so on. The intensity of attraction and repulsion is, however, weaker in each in succession, till it at length becomes insensible. This is prettily exhibited by attaching a key to a magnet, a nail to the key, a smaller nail to that, a sewing needle to the smaller nail, and so on, as long as there is sufficient magnetic force developed, to sustain the concatenation in a state of suspension. Some magnets will sustain a considerable weight; others, of course, are capable of exerting very little force.

The iron is said to be converted into a magnet; or, more briefly, to be *magnetized by induction*; or, to use the French term, to be *magnetized by influence*.

Phenomenon 8. If two magnets be suspended, as in the last experiment, it will be found that the two north poles repel each other, and the two south poles repel each other: but the north pole of the one and south pole of the other mutually attract each other. They will, in consequence of this mutual action upon each other, take positions *generally* different from those which they would each take in the absence of each other.

Phenomenon 9. If the poles of the successive induced magnets spoken of in Phen. 8. be examined as to their nature, by means of their action on the poles of a small magnetic needle, it will be found that each of them is a distinct magnet, each consecutive pair of them having their dissimilar poles in contact. This is known at once by observing which end of the needle is attracted before the next piece of iron is put on, and which after it is added, the needle being applied near the untouched end of the iron.

If, moreover, the pieces of iron be laid on a table, and not in contact, the same phenomena will be observed on the application of the trial needle near their extremities.

When two or more magnets are employed to act by influence on the same piece of iron, the phenomena become more complex, and the operation is called *complex induction*. The phenomena are very curious and interesting.

Phenomenon 10. If the iron be removed it instantly ceases to be magnetic, and may have its position reversed with precisely the same effect as before, each phenomenon taking place now at the end opposite to that where it was exhibited before; and this will be the case, however long the apparatus has been allowed to remain in the position spoken of. If, however, pieces of steel be employed, the inductive influence is less than in the iron: whilst, instead of losing its magnetism instantaneously, as the iron did, it retains a portion of it, and becomes itself a permanent magnet. There are indeed few, if any, pieces of iron and steel in which the magnetic force is wholly lost or wholly retained upon removal; but we here speak of the sensible and approximate circumstances of the phenomena.

Phenomenon 11. If a magnet be broken or any way severed, it is converted into two separate magnets; the two ends of the fragments at which the fracture was made being of opposite kinds to the two ends of the whole bar respectively, as if they had been but two magnets united by opposite poles.

Phenomenon 12. If two magnets be brought near each other, their intensity of action on the vibrations of a needle are affected according to the relative positions of the poles, indicating not only that the direction of the quiescent state of the needle is affected (Phen. 8.), but that the intensity of the magnetic force is also altered. This shows that the magnetized bar itself is affected by the inductive power of the other bar, as soft iron is.

Phenomenon 13. If a mass of soft iron be brought into the vicinity of a magnetic needle, the needle will be *generally* deflected from its natural position in various degrees and directions, according to the form and position of the needle and the mass. When an iron sphere is employed, as a cannon ball, the investigation of the order of the phenomena becomes more simple and easy; and it was by remarking that in this case there was a certain plane in any point of which the needle may be placed with respect to the sphere where the needle would not be at all deflected, that Mr. Barlow was led to prosecute his celebrated experiments on this subject. Mr. Christie remarked that this plane was the plane passing through the centre of the ball, perpendicular to the *natural* direction of the needle itself.

There are also lines on the iron sphere in which if the needle is placed the deflection will be a given quantity.

The same phenomena, however, are exhibited, whatever be the form of the mass. Mr. Barlow experimented on a gun 58 cwt., and found it so. He also found that the action did not depend upon the mass itself, but upon the surface of the mass; as the same effects were produced by a ten-inch ball, a ten-inch shell, and a globe of sheet iron of the same diameter. If, however, the sheet iron was less than $\frac{1}{10}$th of an inch in thickness, the effects were diminished; but up to that degree of thinness they did not seem to vary, whilst after they varied very rapidly, and soon became insensible.

Phenomenon 14. If disks of various metals be put into rapid rotation, they will also deflect the magnetic needle from its natural position. That this is not owing to vibration or vorticity produced in the air is rendered evident by the same effects taking place in a more intense degree in vacuo than in the open air. The phenomenon itself was first observed by Arago in France; but it has been chiefly investigated in this country by Messrs. Herschel, Babbage, Christie, Barlow, Faraday, and Harris, to whose memoirs on the subject, in the *Philosophical Transactions*, the reader is especially referred.

Phenomenon 15. Bars that have long stood in a vertical position, as iron railings, &c., are found to have become permanently magnetic. A bar of soft iron, placed in the natural direction of the magnetic needle, acquires temporary magnetism; and if a bar of steel be left there for a sufficient time, it becomes a permanent magnet. These facts show that the earth itself is a great magnet, and converts the others into magnets by induction. This was

observed so far back as the time of Dr. Gilbert; and it is remarkable that, whilst his great cotemporary Lord Bacon was preceptively urging the new organon in philosophy, Gilbert was actually putting it into the most careful practice. The doctrine of terrestrial induction, as taught by Gilbert, is the doctrine of the present hour, and with scarcely a single improvement in the whole range of the theory.

The foregoing contain the most important phenomena of magnetism which depend upon terrestrial influence merely: those which depend upon electrical influence will be found under the head ELECTRO-MAGNETISM.

Laws of Magnetic Action. — Law 1. The intensity of the attractive force exercised by the north pole of one magnet on the south pole of another, and its repulsive force on the north pole of the second, varies inversely as the square of the distance of those poles; and the like occurs when we consider the action of the south pole of the first magnet on the north and south poles respectively of the other. The same law, precisely, holds with respect to the attraction of a corpuscle of unmagnetized iron.

This is the fundamental law of the science, and may be considered as the source from which the others flow by mathematical reasoning. It has been determined with great care by several philosophers, but especially Michell and Coulomb, by means of the torsion balance. Other laws were, in the earlier state of the science, conjectured to obtain; as, for instance, Newton supposed the forces to vary as the cubes of the distances, and some recent inquirers have contended for the simple inverse of the distances; but Newton's opinion was founded upon insufficient experiments, and that of the authors referred to upon an oversight in their mode of estimating the intensity of the forces. Not the slightest doubt, however, now remains upon the minds of those who are competent to form an opinion of the truth of the law stated above.

Law 2. When the needle is very short in comparison with the distance and length of the magnet, and has its centre fixed immoveably, but is otherwise at liberty to take any directive position, it will so arrange itself that its line of direction will be in the plane drawn through the two poles of the magnet and its own (the needle's) centre of rotation; and the line of the needle's direction, being produced to meet the magnetic line (or line drawn through the poles), will divide the latter into segments estimated from the poles, which are in the ratios of the cubes of the distances of the poles from the centre of the needle. When the needle is not small in comparison, as above, the law becomes more complicated.

Law 3. If two magnetic needles be made to vibrate, the intensities of their magnetic forces are as the squares of their number of vibrations made in the same time. This is true, whatever be the planes in which they vibrate, so far as the force is effective in that plane; but for a direct comparison of the ratio of the intensities without further computation, the vibrations of both needles must, in both cases, be made in the *same plane*. The planes most commonly used for vibration are — the horizontal plane; the plane which has been called the magnetic meridian, or that vertical plane which passes through the natural direction of the needle at the place of observation; and the vertical plane at right angles to this.

Law 4. If the needle be allowed to move vertically in a plane making any angle with the magnetic meridian, the dip in that case is equal to the dip in the magnetic meridian multiplied by the cosine of the inclination of the two planes; and if two planes be taken at right angles, in which the dip is observed, the square of the cotangent of the natural dip at that place is equal to the sum of the squares of the cotangents of the observed dips.

Law 5. The intensity of the horizontal force is equal to the intensity of the whole force multiplied by the cosine of the dip. If, therefore, the same needle be used in all the experiments, and observations be made to determine the dip and horizontal intensity at several different places, the relative intensities of the terrestrial magnetic force can be deduced from those observations by the three last laws for each of the places.

The laws according to which magnetic force is influenced by temperature have been chiefly investigated by Coulomb, Kupffer, Barlow, and Christie. It appears, generally, that between the temperature of $-3°$ and $+127°$ of Fahrenheit, the intensity of magnets decreases as the temperature increases; and that at temperatures above 100° a part of the power of the magnet is permanently destroyed. The effects produced on soft iron by changes of temperature appear to be directly the reverse of those produced on magnets, an increase of temperature causing an increase of magnetic force.

On the Formation of Artificial Magnets. — 1. If a steel bar be held in the natural direction of the needle, and two or three smart blows be given at the upper end with a hammer, it will become a permanent magnet.

2. If the end of a steel bar be placed in contact with one of the poles of a magnet, it will become permanently magnetic by induction. A better plan is to place the needle in a line between the opposite poles of two magnets of equal intensity.

3. Lay the bar flat on a table, and draw another magnet (placed upright upon it) several times from one end to the other, always the same way. Or take two magnets, and lay them horizontally upon the bar to be impregnated, having their dissimilar ends in contact over its middle; and slide each towards the end of the bar. This must be repeated several times. Or, again, instead of laying them horizontally, hold them in any angle of inclination (each in the same angle, estimated from the perpendicular to the middle of the bar), and draw them several times along towards the ends, without varying their inclinations.

The above methods were those originally employed; but when the principles of magnetic induction came to be better understood, more complicated but more effective processes were invented, for the explanation of which reference must be made to works expressly on the subject. (See *Brewster's Treatise on Magnetism.*) Those more complicated processes may be greatly simplified by the substitution of a magnet in the form of a horseshoe for the compound magnets. If placed at once in the middle of the needle to be magnetized, with the poles turned in a direction the reverse of the poles intended to be given to the needle, and then moved backwards and forwards along the surface of the needle, taking care to pass over each half of it an equal number of times, and repeating the same operation on the other side, the needle is speedily and effectually rendered magnetic. This is by far the simplest mode of magnetizing; and it may be considered as a method by induction, the induction being accelerated by the friction.

On the subject of terrestrial magnetism, which at the present time is occupying so much of the attention of scientific men, reference may be made, in addition to the works above cited, to the following: — Hansteen, *Untersuchungen über der Magnetismus der Erde*, 4to. Christiana, 1817; Barlow, *Phil. Trans.* 1833; *Allgemeine Theorie des Magnetischen Vereins im Jahre* 1838, by Gauss and Weber, Leipzig, 1839 (a translation of which will be found in *Taylor's Scientific Memoirs*); *Intensitas Vis Magneticæ Terrestris ad Mensuram Absolutam revocata*, Auctore E. F. Gauss, Gottingæ, 1833; *Major Sabine's Report to the Seventh Meeting of the British Association*, 1838; *The Report of the President and Council of the Royal Society on the Objects of Scientific Inquiry*, 1840; and to an excellent popular abstract of the present state of our knowledge on the subject in the *Quarterly Review* for June, 1840.

MAGNETISM, ANIMAL. This pretended influence, or agent, had its origin in Vienna about the year 1776, when a person of the name of Anthony Mesmer published a thesis *On the Influence of the Planets on the Human Body*. About the same time a Jesuit, called Father Hehl, imagined that by the help of a loadstone and certain steel plates rendered magnetic he had cured several diseases; and being struck with the analogy of Mesmer's views to his own, they entered into a kind of partnership as joint practitioners, and attracted considerable notice; so that, although they soon quarrelled, their system of treatment had acquired some notoriety and many powerful advocates. Hehl continued to practise this new and occult science in Germany; and Mesmer, in 1778, went to Paris, and in the course of a short time performed such wonderful cures, and took care to have them so satisfactorily attested, that his apartments were daily thronged with patients of all ranks, and fees and reputation poured in from all quarters. He here, however, unluckily associated himself with a M. d'Eslon, a medical man, who being more skilful in the art of pleasing patients than his master, contrived to gain the ascendency, and so to disgust Mesmer that he was induced to quit Paris for Spa; where he soon contrived, under the pretence of initiating others in the secrets of his trade, to raise about 14,000*l.*, with which he retired to his native place (Mersburg in Suabia), and left magnetism and the magnetizers to their own resources.

As the jargon of Mesmer has been revived in our own days, it may be worth while to give his own definition of his art, which is quite as intelligible as some of the later versions of it which have recently appeared in London; for, in this "hotbed of quackery," Mesmerism, as it is called, has occasionally taken root, and at one time, but for an accident, which we shall presently notice, threatened to thrive and prosper.

"Animal magnetism," says Mesmer, "is a fluid universally diffused; it is the medium of a mutual influence between the heavenly bodies, the earth, and animated bodies; it is continuous, so as to leave no void; its subtilty admits of no comparison; it is capable of receiving, propagating, communicating, all the impressions of motion; it is susceptible of flux and of reflux. The animal body experiences the effects of this agent; by insinuating itself into the substance of the nerves, it affects them immediately. There are observed, particularly in the human body, properties analogous to those of the mag-

net; and in it are discerned poles equally different and opposite. The action and the virtues of animal magnetism may be communicated from one body to other bodies, animate and inanimate. This action takes place at a remote distance, without the aid of any intermediate body; it is increased and reflected by mirrors; communicated, propagated, augmented, by sound; its virtues may be accumulated, concentrated, transported. Although this fluid is universal, all animal bodies are not equally susceptible of it; there are even some, though a very small number, which have properties so opposite that their very presence destroys all the effects of this fluid on other bodies.

"Animal magnetism is capable of healing diseases of the nerves immediately, and others mediately. It perfects the action of medicines; it excites and directs salutary crises in such a manner that the physician may render himself master of them; by its means he knows the state of health of each individual, and judges with certainty of the origin, the nature, and the progress of the most complicated diseases; he prevents their increase, and succeeds in healing them, without at any time exposing his patient to dangerous effects or troublesome consequences, whatever be the age, the temperament, and the sex. In animal magnetism nature presents a universal method of healing and preserving mankind."

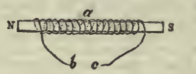
Many of our readers have probably witnessed the silly and disgraceful exhibitions in this line of practice which have lately been tolerated in London, and are therefore aware of the means by which the magnetized are brought under the "influence." It is always necessary that the magnetizer himself should be charged with the fluid, and that the *magnetizees* should be susceptible of its influence, which, be it observed, all persons are not; nor can all persons be magnetizers: some want power, and others faith; in short, there must be a due share of folly or of imposture, or both, on the one hand, and of credulity, cunning, or morbid irritability on the other, and then all goes right. The magnetizer, with his wand of office, performs certain antics before the patient; and the patient either falls asleep or into a fit, or is dumb, or deaf, or garrulous and painfully sensitive to sounds, as the case may be. But it is by no means necessary that the doctor and the person magnetized should see each other: a skilful artist, well charged, can magnetize a fit subject in another room, house, street, or town; and can moreover tell by his own sensations to what extent the influence is communicated, and how the persons receive it.

Mesmer availed himself of certain aids, which our modern practitioners have rejected; such as boxes of steel bars, magnetized water, and musical instruments imbued with the magnetic influence: he also frequently tied his customers together, or made them link their thumbs, when several were to be magnetized at once. When patients are in the crisis, or under the full influence of the power, they can be immmediately roused out of it by certain looks, gestures, and touches of the adept.

To ascertain how far the pretensions of the animal magnetizers were entitled to any attention or support, the French government very properly appointed a committee of scientific and unprejudiced persons to investigate its merits, among whom were Bailly, Franklin, and Lavoisier; and it is curious that their report, which was translated into English, and published here in 1785, is not more often quoted. "This pretended agent," say they, "is not magnetism; for on examining the grand reservoir of the fluid by a needle and electrometer, neither magnetism nor electricity could be detected. We tried it upon ourselves and others without effect; and on blindfolding those who professed great susceptibility of its influence, all its ordinary effects were produced when nothing was done but when they imagined they were magnetized, while none of its effects were produced when they were really magnetized but imagined nothing was done. So also when brought under a magnetized tree; nothing happened if they thought they were at a distance from it, while they immediately went into violent convulsions when they thought they were near the tree, though really not so. The effects, therefore," say the commissioners, "are purely imaginary; and although they have wrought some cures, they are not without danger, for the convulsions sometimes spread among the feeble of body and mind, and especially among women. And, finally, there are parts of the operations which may readily be turned to vicious purposes; and in fact immoral practices have already actually grown out of them."

Some years ago a great animal magnetizer arose in this country, called Perkins, who invented what he called "metallic tractors, for collecting, condensing, and applying animal magnetism;" but Dr. Falconer and Dr. Haygarth of Bath soon put an end to his pretensions, by performing all manner of cures and wonders with a pair of wooden tractors; and as those cases were well attested, they proved, as every person of common sense before knew, that all Perkins's results were imaginary or assumed, and so animal magnetism fell into oblivion. Within the last five years some lamentable attempts have been made to revive it in London; not by quacks and impostors, but by regular practitioners, and even by persons who enjoyed no inconsiderable share of public respect and favour. They have unfortunately reaped the bitter fruits of their credulity and folly; and the mania has again subsided, and will now probably remain dormant.

MAGNE'TO-ELECTRICITY. Under the term Electro-magnetism will be found the description of certain magnetic phenomena produced by electricity. It has been demonstrated by Faraday that electric phenomena may be produced by magnetism, and to these the term *magneto-electricity* has been applied. Let *a* represent a hollow helix of copper wire covered by silk, the ends *b c* of which are connected with a delicate galvanometer; and N S a powerful bar magnet, which can easily be thrust into and withdrawn from the spiral or helix: it will then be found that every time the magnet is pushed into the helix the galvanometer is deflected in one direction, and each time it is withdrawn it is deflected in the opposite direction. On repeatedly threading the helix with the magnet, the deflection also takes place. Now, as the deflection of the galvanometer can only be produced by the motion of electricity in the helix, it is obvious that an electric current is produced each time that the magnet moves through it: hence as, on the one hand, electricity in motion produces magnetism; so, here, magnetism in motion produces electricity. By causing the pole of a powerful magnet to revolve before a coil of wire, or, what amounts to the same thing, if the coil be made to revolve opposite to the pole of a magnet, an electric current will be established in the coil, which may be made sensible by sparks, shocks, and chemical effects.



MA'GNETO'METER. An instrument for measuring the intensity of terrestrial magnetism. The three elements sought to be deduced from magnetic observations are, the declination, the inclination or dip, and the absolute intensity, together with the variations to which they are subject; and each of these elements requires for its determination a peculiar apparatus. A detailed account of the construction and various adjustments of the instruments made use of in the magnetic observatories recently established, and of the methods of observing, will be found in the *Report of the President and Council of the Royal Society on the Objects of Scientific Inquiry in Physics and Meteorology*, 1840. The first accurate measurements of magnetic force were made by Coulomb with the torsion balance; but the more precise method which is now generally adopted, and which depends on the dynamical principle of observing the number of vibrations made by a needle in a given time, was proposed by Graham so long ago as 1722.

MAGNETOMO'TOR. (Lat. lit. *magnet-mover*.) A term applied to a voltaic series of two or more large plates, which producing a great quantity of electricity of low tension is well adapted to the exhibition of electro-magnetic phenomena.

MA'GNITUDE. (Lat.) Size, extent, quantity. This term was originally employed to designate the space occupied by any figure; or, in other words, it was applied to objects strictly termed geometrical, and of three dimensions, — length, breadth, and thickness: then it was extended to designate the quantity of any one of these, and also of angular space, or the inclination of two lines to one another; or, again, the compound idea of a solid angle formed by any number of planes meeting in a point. The amount of any one of these, taken in reference to some standard of the same kind of quantity as that spoken of, was called its magnitude. The term was gradually enlarged in its signification, so as to apply to every kind of quantity that admits of exhibition or mensuration, or of which greater or less can be predicated; and in this sense it was used by Euclid.

MAGNITUDE, APPARENT. The angular space (plane or solid) under which a body appears when viewed from some distant point. The term is chiefly used in speaking of the celestial bodies; and is then employed to express the plane angle subtended by the diameter of the visual disc of the body. It is also used in many branches of optical science, but always with the same *general* meaning.

MAGNOLIA'CEÆ. (Magnolia, one of the genera.) A natural order of Exogenous plants, consisting of trees or shrubs of great beauty, usually with evergreen leaves, and large fragrant flowers. They inhabit the temperate parts of America and Asia, as well as the tropics, and are universal objects of cultivation. The bark of the tulip tree, and of some of the true magnolias, has the reputation of being a good febrifuge.

MA'GPIE. A common species of the Crow tribe, *Corvus pica* of Linnæus; now the type of a distinct genus, *Pica caudata*. They continue in pairs throughout the year, and prey on a variety of food, chiefly animal, as the young of hares, rabbits, and feathered game, young poultry, eggs, carrion, and insects; lastly, fruit and grain.

The magpie is celebrated for its crafty instincts, its power of imitating words, and the propensity which it has in common with other species of the crow tribe to purloin and secrete glittering articles. The nest of the magpie is admirably constructed for strength and warmth, and is commonly defended by a dome. It lays six or seven eggs early in spring, of a yellowish white spotted with brown and cinereous. In winter magpies will assemble in great numbers to roost in some coppice towards the evening, but separate again on the approach of day.

MAHA'BARATA. The name of one of the great Indian epic poems, the subject of which is a long civil war between two dynasties of ancient India, the Kurus and Pandus. This poem embraces the whole circle of Indian mythology; but it is still more valuable as embodying an immense number of historical fragments, which will be of great importance to the future historian of India. Many episodes from the *Mahabarata* have been ably translated by some of our most celebrated orientalists; and parts of the original have been published at different periods in Germany. The period at which the *Mahabarata* was written is wholly unknown, and it has no less baffled all the researches of the learned to discover the date at which it assumed its present methodical form. The *Penny Cyclopædia* contains an able analysis of this poem. *See* RAMAYANA.

MA'HADO. A name of one of the Indian deities, from whom the sacred Ganges is fabled to spring. He is incorrectly used in Goëthe's well-known poem, *Der Gott und die Bajadere*, which begins "Mahadö, du Herr der Erde" (Lord of Earth), as synonymous with Siva.

MAHOMETANISM. *See* MOHAMMEDANISM.

MAI'A. In Grecian Mythology, — 1. The daughter of Atlas and Pleione, one of the Pleiads, who became mother of Mercury by Jupiter: 2. A daughter of the god Faunus, and wife of Vulcan; frequently confounded by mythologists with the former personage.

MAI'DÆ. A family of crabs (Brachyurous Crustaceans), of which the genus *Maia* is the type. The form of the shell is ovoid: the manus and the preceding joint are nearly of the same length. The species called *Maia squinado* is occasionally taken on our own coasts, as well as those of France and of the Mediterranean: it is commonly called the "sea spider."

MAI'DEN. The name given in Scotland to a sharp-edged instrument, formerly used for the beheading of criminals. It resembles in its construction the *guillotine* of the French. *See* GUILLOTINE.

MAIDEN HAIR. The *Adiantum capillus veneris;* a fern found in many parts of Europe on damp shaded rocks. It formed an ingredient in the syrup of capillaire of old pharmacy.

MAIL. (Fr. maille.) A small piece of metal or money, but used collectively to defensive armour formed of iron rings or round meshes. *See* HAUBERK.

MAIL, signified originally the bag which contains letters forwarded by government for the public convenience; but it was soon afterwards extended to the letters themselves, and it is now used also for the conveyance in which they are forwarded. *See* POST OFFICE.

MAILS, or MAILLS. In Scottish Law, the rents of an estate. (Silver halfpence, in England, were anciently called mailes.) In the northern counties of England, and in Scotland, payments made by the occupiers or owners of lands to persons in league with the various classes of freebooters who infested the country were termed *black mail*. To take it was made a capital felony by stat. 43 Eliz. c. 13.

MAIM, or MAYHEM. In old English Jurisprudence, a wound by which any one was so disabled as to be less fit to defend himself in fight; and therefore distinguished from an injury which merely disfigured. Appeal of mayhem was abolished, with other criminal appeals, by 59 G. 3. c. 46. Cutting and stabbing, "with intent to murder," and with intent to maim or disfigure, are now distinct offences, under 9 G. 4. c. 31. s. 11. and 12. The latter was thereby made a capital felony only in such cases in which if death had ensued it would have been murder.

MAI'NTENANCE, in Law, is defined to be an officious intermeddling in a suit that in no way belongs to one, by maintaining and assisting either party with money or otherwise to prosecute or defend it. The punishment by common law is fine and imprisonment, and by 32 H. 8. c. 9. a forfeiture of ten pounds.

MAI'NTENANCE, CAP OF. A cap of dignity, anciently belonging to the rank of a duke; termed by the French *bonnet ducal*. The lord mayor's fur cap is also called a cap of maintenance.

MAIZE (Mais, the American name), a kind of corn extensively cultivated for food, is the grain of the plant named by Linnæus *Zea mays*. Like other corn, it is a species of grass, whose albumen is sufficiently large and farinaceous to be ground into flour. In this plant the grains are unusually large, compressed, and packed closely in regular parallel lines along the sides of a receptacle many inches long. In the young state each grain is tipped with a long slender style as fine as a thread of silk; and many hundreds of such styles being collected together from each receptacle, the whole resemble a silken tassel hanging down from the orifice of the sheathing leaves in which the inflorescence is enwrapped. When ripe the corn is still covered by the sheathing leaves, and is only to be discovered when the latter are stripped back. The male or barren flowers grow in a loose panicle at the end of the stem. There are many varieties of maize; some with stems seven or eight feet high, others not exceeding the stature of two feet; some requiring a long summer to ripen their grain, others coming to perfection in a couple of months. The colour of the grain is also variable; chocolate-coloured, red, crimson, yellow, white, and variegated, are all known to the American planter. This kind of corn is not grown exclusively for the sake of the ripe grain; the young female inflorescence, which is sweet and tender, is boiled or cooked in other ways as a delicate vegetable, and the young stems are occasionally given to cattle. Many attempts have been made to cultivate maize in England as a field crop, but without success. It does not thrive north of the basin of the Mediterranean, and requires a higher summer heat than we experience in these islands.

MA'JESTY. This title of honour is derived from the Romans, among whom it stood for the collective power and dignity of the sovereign body; as majestas populi Romani. Hence treason was termed crimen læsæ majestatis, an injury offered to majesty. Majesty was the attribute of consuls, prætors, &c. only as representing the public; and hence, in later times, when it was transferred to the emperors along with the sovereign power, inferior magistrates were entitled, in ceremonial language, by the appellation of dignitas. Majesty is now the conventional title of European emperors and kings. (The Sultan of Turkey has no more elevated title in our ceremonial than Highness.) It appears to have been first assumed by the German emperors, who were considered as representing the imperial dignity of Rome; then by the French king, Henry II.: in England, by Elizabeth. The Emperor of Austria has the title Majesty, with the prefix K. K. (Kaiserliche, Königliche; *i.e.* Imperial, Royal.)

Apostolical Majesty. — A title bestowed on Stephen, duke of Hungary, about A. D. 1000, by Pope Sylvester II. Re-conferred on the empress-queen Maria Theresa in 1758.

Catholic Majesty. — A title bestowed on Ferdinand and Isabella of Spain by Pope Alexander VI. in 1491, in memory of the conquest of the Moors: it had, however, been borne by earlier Spanish monarchs.

Most Christian Majesty. — A title borne by the kings of France; first solemnly conferred on Louis XI. in 1469 by Pope Paul II.

Most Faithful Majesty. — The title of the kings of Portugal; bestowed by Benedict XIV. on John V.

MA'JOR. In the art Military, a field officer next in rank above a captain, and immediately inferior to a lieutenant-colonel. His chief duties consist in superintending the exercises of his regiment or battalion, and of putting in execution the commands of his superior officer. This class of field officers did not exist till the beginning of the 17th century. The prices of a major's commission and his pay in the British army are as follow: — In the regiments of the line, 3200*l.*; pay, 16*s.* per diem: in the dragoons, 4575*l.*; pay, 19*s.* 3*d.* per diem: in the life and royal horse guards, 5350*l.*; pay, 1*l.* 4*s.* 5*d.* per diem: and in the foot guards (with the rank of colonel), 8300*l.*; pay, 1*l.* 3*s.* This appellation of major does not exist either in the artillery or engineers. *Brigade-major* is a staff officer, who performs for a brigade, or in a garrison, duties equivalent to those of a major in a regiment or battalion. *Major-general* is an officer next in rank below a lieutenant-general, whose functions he has to discharge in the absence of his superior officer.

MAJOR AND MINOR. In Music, terms applied to imperfect concords differing from each other by a semitone minor. They are used in the same sense when applied to discords.

MAJORA'T. In modern legal phraseology, as employed by several Continental nations, the right of succession to property according to age. It is defined "a fidei-commissum gradual, successive, perpetual, indivisible, made with a view to preserve the name, arms, and dignity of a family, and destined for ever to the eldest member of it." In the German empire and in Spain this species of entails is of great antiquity. *See* MAYORAZGO.

MAJORAT, in the French Law, expresses the property, landed or funded, which by virtue of several decrees of the empire might be reserved by individuals enjoying hereditary titles of honour, and attached to the title so as to descend with it. The German and Spanish laws of majorat had no exact equivalent in old France; but a species of majorat existed in the case of the Duchés-Pairies, abolished at the Revolution, with other feudal institutions. The general rule of French law, that children succeed equally to their parents' property, is only modified by the regulations respecting what is termed a "portion disponible." (*Cod. Civil,* art. 913. &c.) A per-

son who leaves one child only can dispose, by will or donation, of half his property; one who leaves two one third, and so on: a person who dies without descendants, but leaving "ascendants," one half or three fourths, according to certain rules; if he leaves only collaterals, he may dispose of the whole.

MA'JOR DOMO. (Lat. major domus, *greater officer of the house.*) In the courts of those kingdoms which were formed out of the fragments of the Western Empire, three different offices seem to be designated by this title, —1. The maître d'hotel, or chief officer of the prince's table, præfectus mensæ, architriclinus, dapifer, &c.; 2. The mayor of the palace (æconomus, *steward*); 3. The first minister, prefect of the palace, count of the palace, &c. Charles Martel is termed major domus by some ancient historians. This title became in later times confounded with that of seneschal. In Germany, under the Othos and the house of Swabia, the dapifer was an officer of high rank, who bore, amongst other duties, the standard of his sovereign. The count palatine was dapifer of the empire: the elector of Bavaria, arch-dapifer. In England he was a personage of less distinction, and his subscription generally appears last among the attesting witnesses to ancient charters.

MAJO'RITY. In Politics, the age at which the sovereign, in hereditary monarchies, becomes capable of exercising supreme authority. *See* MINORITY, REGENT.

MA'JOR TERM, in Logic, is, in a syllogism, the predicate of the conclusion. The major premise is that which contains the major term. In hypothetical syllogisms, the hypothetical premise is called the major.

MAJU'SCULÆ, or CAPITALES LITERÆ. In Diplomatics, capital letters. The Latin manuscripts of the classical age which we possess (those found at Pompeii, and a few parchment MSS. of very early date) are written in capital letters. Few instruments or books of a later date than the sixth century are in capital letters.

MA'LACHITE. (Gr. μαλαχη, *the mallow flower;* or μαλαχος, *soft;* hence, also, called *velvet* copper ore.) The *blue* and *green* carbonate of copper.

MALA'CIA. (Gr. μαλακιον, *a ravenous fish.*) A depraved appetite.

MA'LACODERMS, *Malacodermi.* (Gr. μαλακος, and δερμα, *skin.*) The name of a tribe of Serricorn beetles, including those with a soft and flexible body.

MA'LACOLITE. (Gr. μαλακος.) A variety of *augite* of a dark-green colour.

MALACO'LOGY. (Gr. μαλακια, the Aristotelian name of the Mollusca of the moderns; and λογος, *a discourse.*) The science of the Mollusks. (See that word for their general characters.) Cuvier, the great reviver of this branch of natural history, divides the Mollusks into six classes.

I. *Cephalopoda.*—Mantle in form of a sac, open anteriorly, containing the branchiæ and abdominal viscera; head protruding from the mantle, well developed, and crowned by fleshy productions, by means of which they crawl and seize various objects.

II. *Pteropoda.*—Mantle closed; appendages of the head either wanting or extremely reduced. The principal organs of locomotion are two membranous fins, like wings, situated on the sides of the neck.

III. *Gastropoda.*—These crawl by means of a fleshy disk on their belly. The mouth is supported by a head.

IV. *Acephala.*—The mantle encloses the branchiæ and viscera; the mouth opens within its cavity, and is not supported by a distinct head. The mantle may be open throughout its length, at both ends, or at one extremity only.

V. *Brachiopoda.*—These are also enclosed in a mantle without an apparent head; but have a pair of long, fleshy, ciliated arms, which are spiral when retracted.

VI. *Cirrhopoda.*—This class Cuvier defines as being similar to the other Mollusks in the mantle, branchiæ, &c.; but as differing from them in having numerous horny and articulated limbs, and a nervous system more nearly resembling that of the Articulata.

Since the early form and metamorphoses of the *Cirrhopoda*, or, more properly, *Cirripedia*, were known, most zoologists have regarded them as members of the Articulate sub-kingdom.

The classification of the Mollusca has been much perfected by those zoologists who have been attracted to the study of this department of the animal kingdom by the beautiful and diversified coverings of the testaceous species. Among these Lamarck ranks deservedly the chief; and his system is still that which mainly guides the conchologist in the arrangement of his shells.

The following is the outline of the Lamarckian system:—

In the system of Lamarck, the natural primary group of animals to which the science of malacology relates constitutes the 11th and 12th classes of his Invertebrata. The first of these classes, under the name of *Conchifera*, is equivalent to the Testaceous *Acephala* and *Brachiopoda* of Cuvier; and these low-organized headless Mollusca have their external shelly defensive covering rendered the more complete by way of compensation for the slight development of the nervous centres to which the impressions of external objects are referred, and from which the acts of volition emanate. Instead of one shell, they are therefore provided with and generally completely covered by two shells, which are technically called "valves;" and the *Conchifera* of Lamarck thus include the Mollusks with bivalve shells. These are divided into two orders, *Dimyaria* and *Monomyaria.*

Class I. CONCHIFERA.

Order 1. *Conchifera Dimyaria.*—Char.: Two muscles of attachment at least; shell internally with two muscular impressions, which are separate and lateral.

(1.) Shell regular, generally equivalve.

(A.) Shell gaping in general at the lateral extremities, its valves being approximated.

(*) *Crassipede Conchifers.*—Mantle with its lobes united anteriorly, either entirely or partially; foot thick: gape of the shell wide.

Family 1. *Tubicolidæ.*—Shell either contained in a tubular sheath distinct from its valves, or entirely or partially incrusted in the wall of its sheath, or projecting externally. (*Aspergillum, Clavagella, Teredo,* &c.)

Family 2. *Pholadidæ.*—Shell without a tubular sheath, either furnished with accessory pieces or gaping very much anteriorly. (*Pholas, Gastrochæna.*)

Family 3. *Solenidæ.*—Shell without accessory pieces, and gaping at the lateral extremities only; ligament external. (*Solen, Panopæa, Glycymeris.*)

Family 4. *Myidæ.*—The same characters of the shell, with the ligament internal. (*Mya, Anatina.*)

(**) *Tenuipede Conchifers.*—Mantle with its lobes not united, or hardly united anteriorly; foot small, compressed; gaping of the shell often considerable.

Family 5. *Mactridæ.*

a. Ligament internal only. (*Mactra, Crassatella, Erycina, Lutraria.*)

b. Ligament partly internal, partly external. (*Ungulina, Solemya, Amphidesma.*)

Family 6. *Corbulidæ.*—Shell inequivalve; ligament internal. (*Corbula, Pandora.*)

Family 7. *Lithophagidæ.*—Ligament partly external, partly internal; shells without accessory pieces or any particular sheath, more or less gaping at their anterior side. (*Saxicava, Petricola, Venerupis.*)

Family 8. *Nymphidæ.*—Two cardinal teeth at most in the same valve; shell often gaping a little at the lateral extremities; ligament external; nymphæ in general gaping outwards. (*Sanguinolaria, Psammobia, Tellina, Corbis, Lucina, Donax, Capsa, Crassma.*) *See* CONCHOLOGY.

(B.) Shell closed at the lateral extremities when the valves are shut.

(***) *Lamellipede Conchifers.*—Foot flattened, lamelliform, not posterior.

Family 9. *Conchidæ.*—Three cardinal teeth at least in one valve, with as many or less in the other; lateral teeth sometimes.

1. *Fluviatile Conchidæ.*—Shell with lateral teeth, and covered with a false epiderm. (*Cyclas, Cyrena, Galathea.*)

2. *Marine Conchidæ.*—No lateral teeth in the greater number; rarely an epidermis, which covers the whole shell except the umbones. (*Cyprina, Cytherea, Venus, Venericardia.*)

Family 10. *Cardiidæ.*—Cardinal teeth irregular either in their form or situation, and accompanied in general by one or two lateral teeth. (*Cardium, Cardita, Isocardia,* &c.)

Family 11. *Arcidæ.*—Cardinal teeth small, numerous, intrant, and disposed in each valve on a line, which is either straight or arched or broken. (*Cucullæa, Arca, Pectunculus, Nucula, Trigonia,* and *Castalia.*)

Family 12. *Naiidæ.*—Fluviatile shells, whose hinge is sometimes furnished with an irregular cardinal tooth, which is simple or divided, and with a longitudinal tooth, which is prolonged under the corselet; and sometimes without any tooth at all, or is furnished along its length with irregular granulous tubercles. Umbones with the epidermis peeled off, and frequently eroded. (*Unio, Hyria, Anodon,* and *Iridina.*)

Family 13. *Chamidæ.*—Shell irregular, inequivale; a single cardinal tooth, oblique and subcrenate, inserted into a little pit in the opposite valve; muscular impressions distant, lateral; external ligament depressed. (*Dicras, Chama, Etheria.*)

Order 2.—*Conchifera Monomyaria.*—Only one muscle of attachment, which seems to traverse their body.

Shell with an internal subcentral muscular impression.

(*) Ligament marginal, elongated on the border, sublinear.

Family 14. *Tridacnidæ.* — Shell transverse, equivalve, with an elongated muscular impression bordering the upper limb. (*Tridacna, Hippopus.*)

Family 15. *Mytilidæ.*—Shell longitudinal or subtransverse, with a muscular impression contracted into an isolated space without bordering the limb; hinge with a subinternal ligament, which is marginal, linear, very entire. (*Modiola, Mytilus, Pinna.*)

Family 16. *Malleidæ.* — Ligament sublinear, either interrupted by serial teeth or simple; shell subinequivalve, foliated. (*Crenatula, Perna, Malleus, Avicula.*)

(**) Ligament not marginal, contracted into a short space under the umbones, and not forming a tendinous tube under the shell.

Family 17. *Pectinidæ.* — Shell regular, compact, not foliated. (*Pedum, Lima, Plagiostoma, Pecten, Plicatula, Spondylus, Podopsis.*)

Family 18. *Ostreidæ.*

a. Ligament partly external; shell foliated, but nevertheless often acquiring great thickness. (*Gryphæa, Ostrea, Vulsella.*)

b. Ligament internal; shell delicate, papyraceous. (*Placuna, Anomia.*)

(***) Ligament either wanting or represented by a tendinous chord which sustains the shell.

Family 19. *Rudista.* — Shell very inequivalve. (*Sphærulites, Radiolites, Calceola, Birostrites, Discina, Crania.*)

Family 20. *Brachiopoda.* — Shell adherent, either immediately or by a tendinous chord; mantle bilobate, the lobes separated anteriorly, enveloping the body; two opposed, elongated, fringed arms, near the mouth, rolled spirally when retracted. (*Orbicula, Terebratula, Lingula.*)

Class II. Mollusca.

Order 1. *Pteropoda.* — Char.: No foot for creeping, nor arms for progress or seizing the prey; two fins, opposed and similar, proper for natation; body free and floating; some naked; others with thin, semitransparent, symmetrical shell. (*Hyalæa, Clio, Cleodora, Limacina, Cymbulia, Pneumodermon.*)

Order 2. *Gasteropoda.* — Animals with a straight body, never spiral, nor enveloped in a shell which can contain the entire body; a foot or muscular disc along the whole length of the under part of the body, serving for creeping; some naked; others protected by a dorsal shell not imbedded; and others containing a shell more or less hidden in their mantle.

Section 1. *Hydrobranchiata.* — Branchiæ, whatever be their position, developed either in the form of a network, in laminæ, in a pectinated form, or in a ribbon-like shape. The Gastropods of this section breathe water only.

Family 21. *Tritonidæ.* — Branchiæ external, placed above the mantle, either on the back or on the sides, and not being in any particular cavity. (*Glaucus, Eolis, Tritonia, Scyllæa, Tethys, Doris.*)

Family 22. *Phyllididæ.* — Branchiæ placed under the border of the mantle, and disposed in a longitudinal series around the body, or on one side only, not being in any particular cavity. (*Phyllidia, Chitonellus, Chiton, Patella.*)

Family 23. *Semiphyllididæ.* — Branchiæ placed under the border of the mantle, and disposed in a longitudinal series on the right side of the body only. (*Pleurobranchus, Umbrella.*)

Family 24. *Calyptræidæ.*— Branchiæ placed in a particular cavity upon the back, situated anteriorly near the neck; shell always external, and covering the soft parts. (*Parmophorus, Emarginula, Fissurella, Pileopsis, Calyptræa, Crepidula, Ancylus.*)

Family 25. *Bullidæ.* — Branchiæ placed in a particular cavity towards the posterior part of the back, and covered either by the mantle or by an opercular escutcheon. (*Bulla, Aplysia, Dolabella.*)

Section 2. *Pneumobranchiata.* — Branchiæ creeping, in in the form of a vascular network, on the wall of a particular cavity, the aperture of which is small, and can be contracted or dilated at will. The Gastropods of this section breathe nothing but air.

Family *Limacidæ.* (*See* Limax.)

Order 3. *Trachelipoda.* — Body spiral in its posterior part, which is separated from the foot, and always lodged in a shell; the foot free, flattened, attached to the lower base of the neck or to the anterior part of the body, and serving for creeping; shell spirivalve and sheathing.

Section 1. *Phytiphaga.* — Trachelipods without a projecting siphon, and respiring in general by means of a hole; the greater part phytiphagous, and furnished with jaws; shell with the aperture entire, having at its base neither dorsal subascending notch nor canal.

(*) Breathing air only; shell spirivalve, unarmed, not distinctly nacreous.

Family 26. *Helicidæ.*

a. Four tentacles. (*Helix, Bulimus, Achatina,* &c.)

b. Two tentacles. (*Auricula, Cyclostoma.*)

Family 27. *Limnæidæ.* — Amphibious; living in the water, but coming to the surface to breathe; shell with a sharp edge to the lip. (*Planorbis, Physa, Limnæa.*)

(**) Breathing water only; branchiæ projecting in form of filaments, laminæ, or tufts in the branchial cavity; shell often nacreous, and often also having protuberant parts on the surface.

(*a.*) Shell fluviatile, operculated, the left border of which does not resemble a demi-partition.

Family 28. *Melanidæ.* — Shell with disunited borders. (*Melania, Melanopsis, Pirena.*)

Family 29. *Peristomidæ.* — Shell with united borders. (*Valvata, Paludina, Ampullariæ.*)

(*b.*) Shell fluviatile or marine, the left border resembling a demi-partition.

Family 30. *Neritidæ.* — *Navicella, Neritina* (fluviatile), *Nerita, Natica* (marine).

(*c.*) Shell marine, the left border not resembling a demi-partition.

Family 31. *Janthinidæ.* — Shell floating at the surface of the water. (*Janthina.*)

Family 32. *Macrostomidæ.* — Shell not floating, having the aperture very wide; no columella. (*Sigaretus, Stomatella, Haliotis.*)

Family 33. *Plicacidæ.*—Aperture of shell not very wide; plaits on the columella. (*Tornatella, Pyramidella.*)

Family 34. *Scalaridæ.*—Borders of the aperture united circularly; no plaits on the columella. (*Vermetus, Scalariæ, Delphinula.*)

Family 35. *Turbinidæ.* — Borders of the aperture disunited. (*Solarium, Rotella, Trochus, Monodonta, Turbo, Planaxis, Phasianella, Turritella.*)

Section 2. *Zoophaga.* — Trachelipods with a projecting siphon, and which only breathe water, which reaches the branchiæ by means of this siphon. These feed on animal substances only, are marine, have no jaws, and are furnished with a retractile proboscis. Shell spirivalve, sheathing the soft parts, with an aperture which is either canaliculated, or notched, or turned up at its base.

(*a.*) Shell with a canal more or less long at the base of its aperture, and the right border of whose lip does not change with age.

Family 36. *Canalifera.*

1. No constant process on the right lip of the shell. (*Cerithium, Pleurotoma, Turbinella, Cancellaria, Fasciolaria, Fusus, Pyrula.*)
2. A constant process on the right lip in all the species.

α. No processes on the spire. (*Struthiolaria.*)

β. Processes on the spire. (*Ranella, Murex, Triton.*)

(*b.*) Shell with a canal more or less long at the base of its aperture, and the right border of whose lip changes its form with age, and has a sinus inferiorly.

Family 37. *Alata.* — Wing shells. (*Rostellaria, Pteroceras, Strombus.*)

(*c.*) Shell with a short canal ascending posteriorly, or with an oblique notch at the base of its aperture, this demicanal being directed towards the back.

Family 38. *Purpurifera.*

1. Canal ascending or recurved towards the back. (*Cassis, Cassidaria.*)
2. An oblique notch directed backwards. (*Purpura, Ricinula, Monoceras, Concholepas, Harpa, Dolium, Buccinum, Eburna, Terebra.*)

(*d.*) No canal at the base of the aperture, but a subdorsal notch, and plaits on the columella.

Family 39. *Columellidæ.* — *Columbella, Mitra, Voluta, Marginella, Volvaria.*

(*e.*) Shell without a canal; but having the base of its aperture notched or versant, and the whorls of its spire large, compressed, and enrolled in such a manner that the last whorl nearly entirely covers the others.

Family 40. *Convolutidæ.* — *Ovula, Cypræa, Terebellum, Ancillaria, Oliva, Conus.*

Order 4. *Cephalopoda.* — Mantle in form of a sac, containing the lower part of the body; head projecting from the sac, surrounded by arms, which are not articulated [but furnished with suckers, and which environ the mouth; two sessile eyes; two horny mandibles to the mouth; three hearts*]; sexes separate.

Division 1. *Polythalamous Cephalopods.* — Shell multilocular, enveloped completely or partially, and which is inclosed in the posterior part of the animal, often with adherence.

Family 41. *Orthoceratidæ.* — Shell straight, or nearly so, with simple or not sinuous chambers. (*Belemnites, Orthoceros, Nodosaria, Hippurites, Conilites.*)

Family 42. *Lituolitidæ.* — Shell partially spiral; last

* The characters included within brackets apply only to the 2d division of Lamarck's order.

whorl continued in a straight line. (*Spirula*, *Spirulina*, *Lituola*.)

Family 43. *Cristacidæ.* — Shell semidiscoid; spire eccentric. (*Renulina*, *Cristellaria*, *Orbiculina*.)

Family 44. *Spherulidæ.* — Shell globulose, spheroidal, or oval, with enveloping whorls or partitions united *en tunique*. (*Miliola*, *Gyrogona*, *Melonia*.)

Family 45. *Radiolididæ.* — Shell discoid, with a central spire, and partitions radiating from the centre to the circumference. (*Rotalia*, *Lenticulina*, *Placentula*.)

Family 46. *Nautilidæ.* — Shell discoid, with a central spire, and partitions which do not extend from the centre to the circumference. (*Discorbis*, *Siderolites*, *Polystomella*, *Vorticialis*, *Nummulites*, *Nautilus*.)

Family 47. *Ammonitidæ.* — Shell multilocular, with chambers sinuous at the edges. (*Ammonites*, *Orbulites*, *Ammonoceras*, *Turrilites*, *Baculites*.)

[From regard being only had to the characters afforded by the shell, the Polythalamous Cephalopods of Lamarck form the least natural of his groups. Many of the genera, especially the microscopic species, belong to a different primary division of the animal kingdom; and one genus, *Gyrogona*, to another kingdom of nature, it being a fossil seed. The genera *Belemnites* and *Spirula*, which are true Cephalopods, have been removed to the higher-organized or Dibranchiate order of Cephalopods.]

Division 2. *Monothalamous Cephalopods.* — Shell unilocular, entirely external, and enveloping the animal.

Family 48. Genus *Argonauta*.

Division 3. *Sepiary Cephalopods.* — No shell, either internal or external; a solid free cretaceous or horny body, contained in the interior of the greater part of the animals.

Family 49. Genera *Octopus*, *Loligopsis*, *Loligo*, *Sepia*.

Order 5. *Heteropoda.* — Body free, clongated, swimming horizontally; head distinct; two eyes; no arms surrounding the head; no feet under the belly or under the throat for creeping; one or more fins without any regular order, and not disposed by pairs.

Family 50. Genera *Carinaria*, *Pterotrachea*, *Phylliroe*.

Modifications of more or less importance in the classification of the Mollusca have been proposed by Oken (*Naturgeschichte*, Jena, 1816), Ferussac (1819), De Blainville (1814 and 1825), J. E. Gray (*London Medical Repository*, 1821), Des Hayes, Rang, and others. For an account of the structure and growth of shells, see Conchology.

MALACOPTERY'GIANS, *Malacopterygii*. (Gr. μαλακος, and πτερυξ, *a wing*.) The name of a division of the class of fishes comprehending all those which, with an internal osseous skeleton, have the rays supporting the fins soft, except the first ray of the dorsal and pectoral fins.

MALACO'STRACANS. (Gr. μαλακος, οστρακον, *a shell*.) The name of a division of the class Crustaceans, including those which are covered with a crust softer than the shell of the Mollusks, but firmer than the covering of the Entomostracans. (See that word.) The term *Malacostraca* was first applied by Aristotle to the *Crustacea* of the moderns, being used by him in a comparative sense, as contrasted with the *Ostracoderma*, which are the modern *Testacea*.

MALÆIC ACID. An acid obtained by distilling malic acid at a temperature of about 400°. When malic acid is exposed for a longer time to a moderate heat, it becomes modified into *paramalæic acid*.

MALA'GMA. (Gr. μαλασσειν, *to soften*.) A poultice.

MALA'RIA. (Ital. mal' aria, *a bad air*.) The exhalation of marshy districts, which produces intermittent fevers. This term has now become of general application; but it was long restricted to that district of Italy extending from Leghorn to Terracina in one direction, and from the sea to the Apennines in another. Even in the time of Horace Rome was deserted two months in the year, on account of the dangers of the malaria.

MA'LIC ACID. (Lat. malum, *an apple*.) A peculiar acid contained in the juice of the apple and several other fruits: it may be obtained also from the berries of the *Sorbus aucuparia*, or mountain ash, and has hence been called *sorbic acid*.

MA'LICE (Lat. malitia), in the English Law, does not necessarily bear the signification of particular ill feeling towards an individual, but is a term directly importing wickedness in the commission of an act, and excluding a just cause or excuse. (*See* Murder.) Malicious injury to property is in some instances a felony, in others a misdemeanour; punishable, in some, on summary conviction: the law respecting which is consolidated in one of the statutes commonly called Peel's Acts (7 & 8 G. 4. c. 30.). By sect. 25. of this act it is expressly declared that the word malice, in relation to these injuries, bears its legal and not its popular signification; it being there declared that the act applies, "whether the offence shall be committed from malice conceived against the owner of the property, or otherwise." In civil actions for injuries to which malice is essential, *e.g.* slander, libel, &c., the question of the existence of malice is one, in general, for the jury; but, under certain circumstances, it may be implied by the court from the absence of reasonable and probable cause, as in actions for malicious prosecution.

MALLEABI'LITY. (Lat. malleus, *a hammer*.) The property of being susceptible of extension under the blows of a hammer. It is especially characteristic of some of the metals, and in this quality gold exceeds all the others: common gold leaf is not more than a two hundred thousandth part of an inch in thickness; five grains may be thus extended so as to cover a surface of more than 270 square inches. *See* Ductility.

MA'LLEUS. (Lat. *a hammer*.) One of the small bones of the internal ear, attached to the *membrana tympani*, somewhat in shape resembling a hammer.

Malleus. A genus of Ostracean Bivalves, characterized by having, in addition to the simple pit for the ligament, a notch on the side of the ligament for the passage of a byssus. The species of this genus are called "hammer-oysters." The most noted is the *Ostrea malleus* of Linnæus, which has the cardinal region of the shell forming something like the head of a hammer, of which the elongated valves, extended transversely, represent the handle. It is a native of the Indian archipelago, and still ranks among the number of rare and high-priced shells.

MA'LLOW (Lat. malva.), is a weed common by hedgerows and waysides in Europe. It has mucilaginous properties, and has been employed in the preparation of emollient poultices, in the same way as the marsh mallow. Its fruit is a depressed disk, and is called by the country people "cheeses" (Fr. *Fromageon*).

MA'LLUM. The public assembly or meeting of the people according to the usage of the old Teutonic nations. Under the Carlovingian monarchs the mallum appears to have been summoned by the missus, or deputy of the sovereign. There is a separate mallum for every leading state or kingdom which composed the empire; and it was attended by the notables of all the various races of inhabitants (Roman, Frankish, Gothic, &c.), and in some instances by the Scabini or Echevins, who represented the communities of the towns.

MALMSEY. A strong and fine-flavoured sweet wine, made in Madeira of grapes which have been allowed to shrivel upon the vine; it is of a deep golden hue. It contains between 16 and 17 per cent. of alcohol.

MALT, is used to designate grain which has become sweet in consequence of incipient germination. Malt forms the principal ingredient in the manufacture of beer, and is not used for any other purpose. Three different kinds are employed: 1. pale or amber malt, which yields the saccharine or fermentable extract; 2. brown or blown malt, which is not fermentable, but is used to impart flavour; 3. roasted or black, or as it is sometimes called patent malt, which is employed instead of burnt sugar merely as a colouring matter. The process followed in the manufacture of malt is very simple, and has been carried on for a very long period nearly in the same manner in which it is conducted at present. (See *Thomson's Chemistry*.)

The manufacture of malt has been carried on in England to a great extent from a very early period; but it is singular that notwithstanding the products obtained from it have always formed the principal beverage of the great bulk of the people, the consumption of malt varied very little from the beginning of the last century till within the last half dozen years! This extraordinary result, so different from what would have been *à priori* anticipated, is ascribable partly to the increased duties laid on malt, but still more to the greater increase of those laid on beer, its principal product. No doubt, however, it has been partly, also, occasioned by the change that has taken place in the mode of living by the introduction and universal use of tea, coffee, and other articles substituted in the place of beer. But the increase that has taken place in the consumption of malt since the reduction of the duty on it in 1822, and the repeal of the beer duty in 1830, seems to prove that the duties were at least quite as instrumental in checking the consumption as the introduction of the articles alluded to. Malt was first made to contribute to the public revenue in England in 1697, in Scotland in 1713, and in Ireland in 1785. From the period at which the duty was first levied on malt down to the present time, it has been subject to numerous changes, a succinct account of which will be found in the *Penny Cyclopædia*. The present duty on malt from barley is 2*s*. 7*d*. per bushel, and from bere or bigg 2*s*. The quantity of malt charged with duty in the United Kingdom during the three years ending 1838, averaged 418,148,811 bushels; and the revenue derived from it averaged, in the same period, 5,282,972*l*.

MA'LTHA. A mineralogical term applied to *mineral pitch*; an inflammable bituminous product, probably de-

rived from the exsiccation of mineral tar. A cement containing mineral pitch was used by the ancients for plastering their walls, and was composed of pitch, wax, plaster, and grease. Another sort, with which the Romans used to plaster the interior of their aqueducts, was made of lime incorporated with melted pitch. The various bituminous pavements which have lately come into use are similar combinations.

MALVA'CEÆ. (Malva, one of the genera.) A natural order of mucilaginous Exogenous plants, with polypetalous flowers and monadelphous stamens. The species are herbs, bushes, or trees, and are found all over the temperate and tropical parts of the world, especially the latter. Their flowers are in many cases large and handsome; but the order is chiefly interesting from the *Gossypium*, or true cotton plant, forming a part of it. Another species is the marsh mallow, or *Althæa officinalis;* and some yield a fibre fit for manufacture into cordage.

MA'MELUKE. (Arabic, memalik, *a slave.*) A name applied to the male slaves imported from Circassia into Egypt by the master of that country. In the 13th century, when the countries in the vicinity of Mount Caucasus were ravaged by Gengis Khan, Nojmedden, sultan of Egypt, purchased several thousands of the natives of those regions, especially Turks, and formed them into an armed body of guards. These guards, or Mamelukes, in the sequel, seized on all the power of the country, murdered the sultan Touran Shah, A.D. 1258, and made Ibeg, one of their own number, his successor. After that period the Mamelukes, whose numbers were continually enriched by importations from their own country, governed Egypt 263 years. (See *Gibbon*, vol. xi.) This military sovereignty was destroyed by Selim I., the Turkish sultan, who took Cairo in 1517. Nevertheless, the Mamelukes, under their 24 beys, continued for 200 years more to exercise a power scarcely inferior to that of the Turkish pachas, whom, in the 18th century, they reduced to mere ciphers in the government. Their power was again considerably broken by the French invasion under Buonaparte, to which they offered a determined opposition. After the abandonment of Egypt by the French, the struggle between the beys and the pachas was renewed: finally, in 1811, the present pacha, Mohammed Ali, having invited the principal leaders of the Mamelukes to a banquet, slew 470 of them by treachery, and compelled the remainder to submission.

MA'MERTINE PRISONS. *See* PRISONS.

MAMMA'LIA. (Lat. mamma, *a teat.*) The most highly organized class of animals, at the head of the great scale of organized nature. They possess mammary glands, and suckle their young; the fœtus is developed in the womb. Their external distinguishing marks are a covering of hair, and teats or nipples; but to the manifestation of these two characters there are a few exceptions. The principal anatomical character is the condition of the lungs, which are suspended freely in a thoracic cavity, separated by a perfect diaphragm from the abdomen. The entire tissue of the lungs is occupied by extremely minute air-cells, with highly vascular parietes, so that the air inspired is rapidly decomposed, and breathing can be safely suspended only for a short time. The whole mass of circulating blood is transmitted to the lungs by the mechanism of a pulmonary auricle and ventricle, equally perfect, and inferior only in power to the systemic auricle and ventricle, which subsequently propel the aërated blood to the general system: the heart consequently consists of four distinct cavities.

The upper jaw of the Mammalia is fixed; the two rami of the lower jaw consist each of a single bony piece, and are articulated by a convex or flat condyle to the base of the zygomatic process, and not the tympanic element of the temporal bone. With a few exceptions, the jaws of the Mammalia are armed with teeth: these are arranged in a single row, are lodged in sockets, sometimes by two or more fangs, and are never anchylosed to the substance of the jaw. A deciduous tooth is never succeeded by more than one corresponding tooth in the vertical direction. The tongue is fleshy, well developed, with the apex more or less free. The posterior openings of the nasal passages are protected by the "soft palate," and the larynx, or opening of the wind-pipe, by an "epiglottis." The alimentary canal varies with the nature of the food, but the "cœcum coli" is usually single. The rectum commonly terminates by a distinct aperture behind the urinary and generative orifices.

The bodies of the vertebræ have their articular surfaces more or less flattened, and always joined together by a series of concentric ligaments with interposed glairy fluid. The cervical vertebræ, with one or two exceptions, are seven in number. The atlas is articulated by two surfaces to two occipital condyles, developed from the ex-occipital elements. With two exceptions, the coracoid bone appears as a small process or appendage of the scapula. The sternum is narrow, and consists of a simple longitudinal series of bones.

The brain presents its highest state of development in the Mammalia: it consists of a cerebrum, which is generally more or less convoluted, a cerebellum with lateral lobes, and a medulla oblongata with a distinct "tuber annulare." The optic lobes are solid, divided by a transverse fissure, and hence called "bigeminal bodies:" they are situated on the upper part of the crura cerebri, and are generally concealed by the overlapping posterior cerebral lobes. The rudiment of the "corpus callosum," or great cerebral commissure, first begins to be distinctly recognizable in the Implacental Mammalia; and in a state of normal development, or where it bears a direct proportion to the size of the corpora striata or hemispheres of the brain, it is peculiar to the Placental Mammalia.

The eyes of the Mammalia are never complicated with a pecten or marsupium, a choroid gland, or sclerotic bony plates.

The organ of hearing acquires in the Mammalia a fully developed cochlea with a "lamina spiralis:" there are three distinct ossicles in the tympanum; the drum, or membrana tympani, is usually concave towards the meatus, which generally commences with a more or less complicated external ear, supported by a distinct fibro-cartilage.

The Mammalia, without exception, bring forth their young alive; hence they were termed by Aristotle *Zootoca.* This phenomenon is, however, by no means peculiar to the present class; but it was supposed that they differed from other viviparous animals, as the viper, in the development of the germ by means of a placenta. Such, however, is not the case with the marsupial animals, and probably not with the Monotremes; and as the absence of the placenta is associated with several important modifications of structure in the species so developed, by which they approximate to the characters of the oviparous classes, the class Mammalia may be primarily divided into two great sub-classes, called *Placentalia* and *Implacentalia.*

Before, however, the subdivisions of these groups are characterized, it may be advantageous to trace the principal steps by which the present views of the affinities and classification of the Mammalia have been acquired.

Aristotle, although he has left no evidence of a systematic arrangement of the Mammalia in which the succession and subordination of the orders and families are methodically laid down, was nevertheless the first who indicated the larger groups into which the Mammalia resolved themselves, according to their natural affinities.

We may infer, *e. g.*, from one part of the *Historia Animalium*, that the *Zootoca* would be divided, according to the nature of their locomotive organs, into three sections: —1st, *Dipoda*, or bipeds; 2d, *Tetrapoda*, or quadrupeds; and, 3d, *Apoda*, or impeds. Man is cited as the type of the first, and the whale tribe is included in the last of these primary groups; the second embraces all the rest of the class, which, in common language, are called quadrupeds. These Aristotle subdivides into two great natural groups, according to the modifications of the organs of touch. In the first a part of the digits is left free for the exercise of the tactile faculty, the nail or claw being placed upon one side only; in the second group the extremities of the digits are enclosed in hoofs.

The first of these subdivisions is acknowledged to be natural, and has been retained by modern mammalogists under the name of *Unguiculata.* The following families were characterized in it by Aristotle: — 1st, those which have the front teeth trenchant, and the back teeth flattened, as the *Pithecoida* or apes, and the *Dermaptera* or bats; 2d, those with acuminated, trenchant, or carnivorous teeth, which Aristotle calls *Karcharodonta;* 3d, the Rodent quadrupeds, which are indicated by a negative dental character. With respect to the hoofed or "ungulate" quadrupeds, Aristotle points out subordinate groups, and characterizes them by modifications of the feet. Thus, the 1st are the *Polyschidæ* or multungulate quadrupeds, as the elephant; the 2d are the *Dischidæ* or bisulcate quadrupeds, as the Ruminants and hog; the 3d are the *Aschidæ*, or solidungulate quadrupeds, as the horse and ass. From the imperfect mode in which the zoological writings of the Stagyrite have been handed down, we have not the means of knowing whether Aristotle viewed any of the groups thus defined in their relation of subordination to each other, or in the spirit of modern classification; for although they agree in relative value with those termed *Classes*, *Orders*, *Families*, *Genera*, yet Aristotle applies to each of them the same denomination, viz. *genos*, or genus.

The honour of having formed an original scheme for the classification of quadrupeds, in which the subordination of characters and of groups is attended to, is due to our great countryman Ray. From Aristotle to his time the classification of the Mammalia received no improvement worthy of notice. Ray's arrangement is given in a tabular form, in his *Synopsis Methodica Animalium Quadrupedum;* and is as follows: —

A Table of Viviparous Four-footed Animals.

Viviparous hairy animals or quadrupeds are, —

- *Ungulate;* and these either
  - *Solidipedous*, as the Horse, Ass, Zebra.
  - or *Bisulcate*, which are
    - *Ruminants* with horns, that are
      - Persistent, as in the Ox, Sheep, Goat;
      - or Deciduous, as in the Stag.
    - or *Not Ruminants*, as the Hog.
  - *Quadrisulcate*, as the Rhinoceros, Hippopotamus.
- or *Unguiculate*, whose feet are either
  - *Bifid*, as in the Camel, or
  - *Multifid*, which are
    - With *digits* adhering together, and covered with a common integument, so that the extremities alone are visible at the margin of the foot, and are covered with obtuse nails, as in the Elephant.
    - With *digits* in some measure distinct, and separable from each other, the nails being
      - *Depressed*, as in Apes;
      - or *Compressed*, where the incisor teeth are
        - *Many*, in which group all the animals are carnivorous and rapacious, or at least insectivorous, or subsist on insects, with vegetable matter.
          - *The larger ones* with the
            - *Muzzle short*, and head rounded, as the Feline tribe; or with the
            - *Muzzle long*, as the Canine tribe.
          - *The smaller ones* with a long slender body, and short extremities, as the Weasel or Vermine* tribe.
        - or *Two very large*, of which tribe all the species are phytivorous, as the Hare.

"The anomalous species," he afterwards observes, "among the viviparous quadrupeds, with a multifid foot, are the hedgehog, the armadillo, the mole, the shrew, the tamandua, the bat, and the sloth. The first five of these species agree with the *canine* and *vermine genera* in their elongated muzzle, but differ from them in the form and disposition of the teeth; the tamandua, indeed, is altogether destitute of teeth: the remaining two anomalous species have the muzzle shortened."

Linnæus defines the class Mammalia as follows: — *Heart* with two auricles and two ventricles; blood warm; *lungs* respiring reciprocally (*pulmones respirantes reciproce*); *jaws* incumbent, covered, armed with teeth in most; penis intrans; generation viviparous, lactiferous; *senses*, tongue, nostrils, eyes, ears, tactile papillæ; *covering*, hairs few in tropical, very sparing in aquatic, mammals; *support*, four feet, except in those which are entirely aquatic, in which the posterior feet are bound together in the fin of the tail; a *tail* in most.

Linnæus, like Aristotle and Ray, founds his primary divisions of the class Mammalia on the locomotive organs; but his secondary divisions or orders are taken chiefly from modifications of the dentary system. The following is the scheme of his arrangement: —

Mammalia.

Unguiculate	Front teeth, none in either jaw	*Bruta.*
	Front teeth, *cutters* 2, laniaries 0	*Glires.*
	Front teeth, *cutters* 4, laniaries 1	*Primates.*
	Front teeth, *piercers* (6, 2, 10), laniaries 1	*Feræ.*
Ungulate	Front teeth, in both upper and lower jaw	*Belluæ.*
	Front teeth, none in the upper jaw	*Pecora.*
Muticate	Teeth variable	*Cete.*

(From the *Systema Naturæ*, ed. 16. Holmiæ, p. 24.)

On comparing the three preceding systems, it will be found that the most important errors of arrangement have been committed, not by Aristotle, but by the modern naturalists. Both Ray and Linnæus have mistaken the character of the horny parts enveloping the toes of the elephant, which do not defend the upper part merely, as is the case with claws, but embrace the under parts also, forming a complete case or hoof.

With respect to Linnæus, however, it must be observed, that although he has followed Ray in placing the elephant in the unguiculate group of quadrupeds, he has not overlooked the great natural divisions which the latter naturalist adopted from Aristotle, as is evident from the table above quoted. He erred, perhaps, in not giving names to those primary divisions.

From the manner in which Linnæus has arranged his orders in this table, it would seem that he had the circular progression of affinities in view. The walrus among *Bruta* connects the commencement of the chain with *Cete*, which forms the last link; but whether or not he had perceived the affinity of *Elephas* to the *Glires*, and intended it as the transitional genus to that order, as Cuvier has subsequently shown, is less certain.

Pallas, in his great posthumous work, entitled *Zoographia Rosso-Asiatica*, has given the following outline of a *Systema Mammalium:* —

Classis Lactantia.

Ordo I. *Feræ.* — 1. Felis; 2. Canis; 3. Ursus; 4. Méles; 5. Viverra; 6. Mustela; 7. Phoca.

Ordo II. *Semiferæ.* — 1. Simia; 2. Lemur; 3. Didelphys; 4. Vespertilio; 5. Talpa; 6. Sorex; 7. Erinaceus.

III. *Glires.* — 1. Hystrix; 2. Castor; 3. Lepus; 4. Arctomys; 5. Spalax; 6. Cricetus; 7. Mus; 8. Myoda; 9. Myoxus; 10. Dipus; 11. Sciurus.

IV. *Ruminantia.*—1. Camelus; 2. Moschus; 3. Cervus; 4. Ægoceros; 5. Bos; 6. Antilopes.

V. *Anomalopoda.* — 1. Equus; 2. Sus; 3. Rhinoceros; 4. Hippopotamus.

VI. *Belluæ.* — 1. Elephas; 2. Rosmarus.

VII. *Cetacea.* — 1. Manatus; 2. Delphinus; 3. Physeter; 4. Balæna; 5. Ceratodon.

We shall now proceed to the arrangement of the Mammalia proposed by Cuvier in the last edition of the *Règne Animal;* and this is the more interesting, as, in giving the outline of this method, Cuvier develops the principles on which his divisions are founded.

"The characters by which Mammalia differ most essentially one from another are derived from the organs of touch, from which results their degree of dexterity; and from the organs of mastication, which determine the nature of their food; and upon these very closely depends not only every thing which is connected with the digestive functions, but a variety of other circumstances relative even to their degrees of intelligence.

"The perfection of the organs of touch is estimated by the number and mobility of the digits, and the extent to which they are enclosed in a claw or in a hoof. A hoof which completely encloses that part of the digit which touches the ground precludes the exercise of it as an organ of touch or of prehension. The opposite extreme is where the nail, in the form of a simple lamina, covers only one side of the end of the digit, leaving the other side in possession of all its delicacy of tact.

"The kind of food is indicated by the molar teeth, to the form of which the articulation of the jaws invariably corresponds.

"For cutting flesh, the molar teeth must be trenchant and serrated; and the jaws fitted together, so as to move like the blades of a pair of scissars, simply opening and closing in the vertical direction.

"For bruising grains and roots, the molar teeth must have flattened crowns, and the jaws a horizontal motion: and further, that the grinding surface may be always unequal, like a millstone, the teeth must be composed of substances of different degrees of density, and consequently wearing down in different proportions.

"The ungulate quadrupeds are all of necessity herbivorous, or with flat-crowned molares, because the conformation of their feet does not permit them to seize living prey.

"The unguiculate animals are susceptible of more variety. They are not limited to one kind of food; and besides the consequent variation in the form of their molares, they differ materially from each other in the mobility and sensibility of their digits. There is, moreover, a characteristic which prodigiously influences their dexterity, and gives variety to their modes of action: it is the faculty of opposing a thumb to the other fingers, so as to seize the smallest objects, which constitutes a

* Genus *Vermineum*, from their wormlike form.

hand, properly so called. This faculty is carried to its highest degree of perfection in man, in whom the whole anterior extremity is free, and can be exclusively employed in prehension. These different combinations, which strictly determine the nature of the several mammiferous animals, have formed the grounds for their distribution into the following orders: —

"Amongst the unguiculate animals, the first is man, who, in addition to his peculiar privileges in every other respect, is distinguished, zoologically, by possessing hands on the anterior extremities alone; the posterior extremities being destined to sustain him in an erect position.

"The order which comes nearest to man — that termed *Quadrumana* — has hands on the four extremities.

"Another order, termed *Carnivora*, has not the thumb free and opposable on the anterior extremities.

"These three orders possess, likewise, severally, the three kinds of teeth; viz. molars, laniaries, and incisors.

"The quadrupeds of the fourth order, viz. the *Rodentia*, have the digits differing little from those of the *Carnivora*; but they want the laniary teeth, and have the incisors of a form and disposition altogether peculiar to themselves.

"To these succeed the animals whose digits now bebecome much cramped, being sunk deep in large and, most commonly, crooked claws. They are further defective in the absence of incisor teeth; some of them even want the laniaries, and others are altogether destitute of dentary organs. We shall comprehend them under the term *Edentata*.

"This distribution of unguiculate animals would be perfect, and would form a very regular chain, if New Holland had not lately furnished us with a small collateral chain, composed of the *Marsupial* animals, all the genera of which, while they are connected by a general similarity of organization, at the same time correspond, in their dentition and diet, some to the *Carnivora*, others to the *Rodentia*, and a third tribe to the *Edentata*.

"The ungulate animals are less numerous, and present fewer variations of form.

The *Ruminantia*, by their cloven feet, their want of upper incisors, and their complicated stomach, form a very distinct order.

"All the other quadrupeds with hoofs might be united into a single order, which I would call *Pachydermata* or *Jumenta*; the elephant excepted, which might form an order of itself, having some remote affinities to the order *Rodentia*.

"Last of all come the Mammalia which have no hinder extremities, and whose fish-like form and aquatic life would induce us to form them into a separate class, if their economy was not in every other respect the same as in the class in which we shall leave them. They are the warm-blooded fishes of the ancients, or the *Cetacea*, which, combining the powers of other Mammalia with the advantage of being sustained upon the watery element, include the most gigantic forms to be found in the whole animal creation." (*Règne Animal*, 2d ed. p. 65.)

The proofs that the small collateral chain of mammals which New Holland has principally furnished form a distinct primary group in that class, have been successively established in the memoirs by Mr. Owen on the Generation, the Structure of the Brain, the Osteology, and the Classification of the Marsupial Animals, and on the Mammary Glands, the Ovum, and the Young of the Ornithorhynchus, published in the *Philosophical* and *Zoological Transactions*. In the latest classifications of the Mammalia (Charles Lucien Buonaparte, *Systema Vertebratorum*; Martin, *History of Mammalia*), the binary division of the class Mammalia, founded on the anatomical and physiological facts detailed in those memoirs, has been adopted.

The first of these divisions, which we have proposed to call subclass PLACENTALIA, includes the following orders: —

I. *Bimana.* — Ex.: Man.
II. *Quadrumana.* — Ex.: Ape, Monkey, Lemur.
III. *Cheiroptera.* — Ex.: Bat.
IV. *Insectivora.* — Ex.: Shrew, Mole, Hedgehog.
V. *Carnivora.* — Ex.: Dog, Civet, Cat, Weasel, Bear, Seal.
VI. *Cetacea.* — Ex.: Porpoise, Whale.
VII. *Pachyderma.* — Ex.: Manatee, Hippopotamus, Elephant, Hog, Horse.
VIII. *Ruminantia.* — Ex.: Camel, Deer, Antilope, Ox.
IX. *Edentata.* — Ex.: Sloth, Anteater, Manis, Armadillo.
X. *Rodentia.* — Ex.: Rat, Squirrel, Rabbit, Guinea-pig.

The second division, or the subclass IMPLACENTALIA, includes the orders,

XI. *Marsupiata.* — Ex.: Wombat, Kangaroo, Opossum.
XII. *Monotremata.* — Ex.: Ornithorhynchus.

Besides the modification introduced into the Cuvierian system in the binary subdivision of the class, there are a few minor differences in the above classification on which some explanation is requisite.

From Pallas's great group of *Semiferæ*, the families of which he conceived to be linked together by an uninterrupted series of affinities, the *Simiæ* and *Opossums* are removed, in the Cuvierian system, to form the types of two distinct orders: we conceive that the modification of the locomotive system, by which the bat is enabled to fly, is as cogent an argument for regarding it as the type of an order, as the hinder hands are in the case of the ape and lemur. The *Insectivora*, also, in their continuous dental series, comparatively feeble canines, and generally perfect clavicles, seem to claim equivalency of rank with the remaining *Carnassiers* of the Cuvierian system, which will thus correspond with the *Feræ* of Pallas. From the seals, with their largely developed brains, acuminated teeth, and rudimental hind fins, the transition seems most natural to the piscivorous *Cetacea*. The herbivorous *Cetacea*, for reasons given at length in the *Proceedings of the Zoological Society*, 1838, we propose to remove to the *Pachyderma*, between which and the true *Cetacea* they unquestionably form transitional links. No linear arrangement of the orders of a class can ever express more than a part of their mutual affinities. If we were to place them according to their natural relations, the *Quadrumana* would occupy the centre of the class, as from these the greatest number and variety of affinities seem to radiate. Thus, the genus *Galeopithecus* leads to the *Cheiroptera*, the *Lemur* to the *Carnivora*, the *Loris* to the sloths among the *Edentata*; while with the *Rodentia* the *Lemurs* claim close alliance through the *Cheiromys* or *Aye-aye*. The *Insectivora* closely approach one extreme of the implacental group, while the *Edentata* join the other. The *Rodentia* approach still more closely to the marsupial wombat. The *Rodentia*, again, by the *Capybara* and the extinct *Toxodon*, evidently merge into the *Pachyderma*; and the Patagonian hare seems to lead them to the small musk-deer among the *Ruminantia*. The *Edentata* have lost in the mailed *Glyptodon* a transitional step to the thick and tubercular-hided rhinoceros. The twofold affinity of the *Cetacea* to the seals on the one hand, and to the manatee and the hippopotamus on other, has been already alluded to.

In this reticulate interweaving of affinities, under which image the true relations of the Mammalia, as at present known, can alone be impartially and faithfully expressed, it will be observed that, as the series diverge from the *Quadrumana*, they likewise descend; so that the scheme may be likened to a cone, of which Man is the culminating point.

From different points at the base of this cone the connection may be traced with the inferior classes: the most direct transition appears to be made by the Monotremes to the class of Reptiles. The extinct *Enaliosauria* once formed a transition, perhaps not less close, from the crocodiles to the *Cetacea*. The *Pterodactyles* seem to have connected the *Cheiroptera* with the flying ovipara. The Mammalia which present the closest relations to birds are the marsupial *Petaurists*, and the arboreal *Rodents*; but the hiatus is great. Between mammals and fishes, the reptiles interpose at all points; the extinct *Ichthyosaurus* seems to have been the transitional step from the *Cetacea* to the true fishes.

MAMMA'LOGY. (Lat. mamma, *a teat*; Gr. λογος, *a discourse*.) The science of Mammals: the doctrine of their organization, habits, properties, and classification. *See* MAMMALIA.

MA'MMIFERS, *Mammifera*. (Lat. mamma, *a teat*; fero, *I bear*.) A term synonimous with Mammals, or Mammalia.

MAMMI'LLARY. (Lat. dim. mammilla.) In Geology, a surface studded over with rounded projections.

MA'MMON (Syr.), used in scripture to signify either riches, or the god thereof. By poetic licence Milton makes Mammon one of the fallen angels, and has pourtrayed his character in some admirable lines, which are too well known to be cited here.

MA'MMOTH. A word of Tartar origin, applied in Siberia to burrowing animals. It is commonly applied to an extinct species of elephant (*Elephas primigenius*, Blum.). The remains of this animal occur pretty frequently in the newer tertiary deposits in England, the continent of Europe, and Asia. In Siberia an entire animal has been discovered, with the soft parts preserved in the frozen soil of the banks of a Siberian river. The particulars of this remarkable discovery are as follow: — In 1799, a Tungusian, named Schumarhoff, who generally went to hunt and fish at the peninsula at Tamut, after the fishing season of the Lena was over had constructed for his wife some cabins on the banks of the lake Opcoul, and had embarked to seek along the coasts for mammoth horns (tusks). One day he saw among the blocks of ice a shapeless mass, but did not then discover what it was. In 1800 he perceived that this object was more disengaged from the ice, and that it had two projecting parts; and, towards the end of the summer 1801, the entire side of the animal and one of his tusks were quite free from ice.

The summer of 1802 was cold; but, in 1803, part of the ice between the earth and the mammoth, for such was the object, having melted more rapidly than the rest, the plane of its support became inclined, and the enormous mass fell by its own weight on the bank of sand. In March, 1804, Schumarhoff came to his mammoth, and, having cut off the tusks, exchanged them with a merchant for goods of the value of fifty rubles. Adams gives the following account of this remarkable occurrence. "Two years afterwards, or the seventh after the discovery of the mammoth, I fortunately traversed these distant and desert regions, and I congratulate myself in being able to prove a fact which appears so improbable. I found the mammoth still in the same place, but altogether mutilated. The prejudices being dissipated, because the Tungusian chief had recovered, there was no obstacle to prevent approach to the carcass of the mammoth; the proprietor was content with his profit from the tusks, and the Jalutski of the neighbourhood had cut off the flesh, with which they fed their dogs during the scarcity. Wild beasts, such as white bears, wolves, wolverines, and foxes, also fed upon it, and the traces of their footsteps were seen around. The skeleton, almost entirely cleared of its flesh, remained whole, with the exception of one fore-leg, the spine, from the head to the os coccygis, one scapula: the bones of the other three extremities were still held together by the ligaments and by parts of the skin. The head was covered with a dry skin: one of the ears, well preserved, was furnished with a tuft of hairs. All these parts have necessarily been injured in transporting them a distance of 11,000 wersts (7330 miles); yet the eyes have been preserved, and the pupil of the eye can still be distinguished. This mammoth was a male, with a long mane on the neck, but without tail or proboscis." (The places of the insertion of the muscles of the proboscis are, it is asserted, visible on the skull; and it was probably devoured, as well as the end of the tail.) "The skin, of which I possess three fourths, is of a dark-grey colour, covered with a reddish wool and black hairs. The dampness of the spot where the animal had lain so long had in some degree destroyed the hair. The entire carcass, of which I collected the bones on the spot, is 4 archines (9 feet 4 inches) high, and 7 archines (16 feet 4 inches) long, from the point of the nose to the end of the tail, without including the tusks, which are a toise and a half (9 feet 6 inches), measuring along the curve: the distance from the base or root of the tusk to the point is 3 feet 7 inches in length; the two together weighed 360 lbs. avoirdupois; the head alone with the tusks weighs 11 poods and a half (414 lbs. avoirdupois). The principal object of my care was to separate the bones, to arrange them, and put them up safely, which was done with particular attention. I had the satisfaction to find the other scapula, which had remained not far off. I next detached the skin of the side on which the animal had lain, which was well preserved. This skin was of such extraordinary weight, that ten persons found great difficulty in transporting it to the shore. After this I dug the ground in different places, to ascertain whether any of its bones were buried, but principally to collect all the hairs which the white bears had trod into the ground while devouring the flesh. Although this was difficult, from the want of proper instruments, I succeeded in collecting more than a pood (36 pounds) of hair. In a few days the task was completed, and I found myself in possession of a treasure which amply recompensed me for the fatigues and dangers of the journey, and the considerable expenses of the enterprise. The place where I found the mammoth is about 60 paces distant from the shore, and nearly a hundred paces from the escarpment of the ice from which it had fallen. The escarpment occupies exactly the middle between the two points of the peninsula, and is three wersts long (two miles); and, in the place where the mammoth was found, this rock has a perpendicular elevation of 30 or 40 toises. Its substance is a clear pure ice; it inclines towards the sea; its top is covered with a layer of moss and friable earth, half an archine (14 inches) in thickness. During the heat of the month of July, a part of this crust is melted, but the rest remains frozen. Curiosity induced me to ascend two other hills at some distance from the sea: they were of the same substance, and less covered with moss. In various places were seen enormous pieces of wood of all kinds produced in Siberia; and also mammoths' horns (tusks), in great numbers, appeared between the hollows of the rocks: they all were of astonishing freshness. How all these things could become collected is as curious as difficult to resolve. The inhabitants of the coast call this kind of wood *adaincina*, and distinguish it from the floating pieces of wood which are brought down by the large rivers to the ocean, and collect in masses on the shores of the Frozen Sea: the latter are called *macheina*. I have seen, when the ice melts, large lumps of earth detached from the hills mix with the water, and form thick muddy torrents, which roll slowly towards the sea. The earth forms wedges which fill up the spaces between the blocks of ice. The escarpment of the ice was 35 to 40 toises high; and, according to the report of the Tungusians, the animal was, when they first saw it, seven toises below the surface of the ice, &c. On arriving with the mammoth at Boschaya, our first care was to separate the remaining flesh and ligaments from the bones, which were then packed up. When I arrived at Jakutsk I had the good fortune to repurchase the tusks, and from thence expedited them to St. Petersburg. This skeleton is now in the museum of the academy, and the skin still remains attached to the head and feet." A part of the skin, and some of the hair of this animal, were sent by Mr. Adams to Sir Joseph Banks, who presented them to the museum of the Royal College of Surgeons. The hair is entirely separated from the skin, excepting in one very small part, where it still remains attached. It consists of two sorts — common hair and bristles; that remaining fixed on the skin is of the colour of the camel, an inch and a half long, very thick set, and curled in locks: it is interspersed with a few bristles, about three inches long, of a dark reddish colour. The skin when first brought to the museum was offensive; it is now quite dry and hard, and where most compact is half an inch thick. Its colour is the dull black of the living elephant's skin.

MAN. (Germ. mann; probably from the Lat. *humanus* or *mens.*) Of all living beings on the surface of this planet the first is man; who, in addition to his peculiar privileges in every other respect, is distinguished zoologically by possessing a hand on the anterior extremities only, the posterior or lower limbs being destined to sustain him in an erect position. He is, however, naked, and without natural defensive or destructive weapons. It is the modifications of the bones and muscles of the lower extremities, and especially of the feet, that constitute the most striking anatomical characters of the human species; but with these are associated many other characteristic conditions of the general frame-work of the body, which, as they have been nowhere so accurately, truly, and eloquently set forth as in the lectures of Professor Green, we shall take the liberty to give in the words of that philosophic anatomist and accomplished writer. "In a comparison of the frame and capabilities of man with those of the inferior animals, if we take the human frame as the ideal standard of form, it will be found that all others present so many declensions from the idea by exaggeration or defect; and it will be found from this survey that man is unquestionably endowed with that structure, the perfection of which is revealed in such a balanced relation of the parts to a whole as may best fit it for a being exercising intelligent choice, and destined for moral freedom. It is not, therefore, an absolute perfection of the constituents singly, but the proportional development of all, and their harmonious constitution to One, for which we contend; — a constitution which implies in a far higher degree than in any other animal a balanced relation of the living powers and faculties, and which requires, therefore, in man pre-eminently the endowment of rational will as necessary for the control and adjustment of the balance. Man has not the quick hearing of the timid herbivorous animals; but it was not intended that he should catch the sound of distant danger, and be governed by his fears: he has not the piercing sight of the eagle, nor the keen scent of the beast of prey; but neither was man intended to be the fellow of the tiger, or a denizen of the forest. Hence the departure from the perfect proportion of man which we observe in the inferior animals may be regarded as deformities by exaggeration or defect, dependent upon a preponderance of a part that necessitates a particular use, or the absence of a part that deprives the animal of a power, and in both instances alike abrogates that freedom for which provision is made in the balanced relation of the constituents of the human fabric, which permits the free choice of means, and the adaptation to any purpose determined by an intelligent free-will. Dilate the head, and you have a symptom of disease; protrude the jaws, you have a voracious animal; lengthen the ears, timidity is expressed; let the nose project, and the animal is governed by its scent; enlarge the belly, and you are reminded of the animal appetites: long arms may fit him for an inhabitant of the trees, and a fit companion for the ape; and predominant length of legs are infallibly associated with the habits of the wading or leaping animals. In all, regarding man's form with reference to his destination as the ideal standard, the means become ends; deformity prevails, and becomes the badge of unintelligent slavery to the mere animal nature.

"This may be further illustrated by a general and brief comparison of the components of the skeleton in the vertebrated animals with that of man. In considering the skull, it will be found that man, of all animals, has the largest and roundest cranium. From the ape to the fish the brain-case decreases in capacity, in correspondence with a proportionably diminishing development: but in the same ratio the parts allotted to the senses, and the parts merely subservient to the preparation of the food, increase in size. In looking at the head of the

horse and the dog, it will be readily observed how much the cranium recedes and the jaws protrude; but in birds, reptiles, and fish, the proportions are so altered by the diminution of the cranium that the whole head appears almost to consist of the jaws: witness the mandibles of the stork and pelican, and the enormous jaws of the crocodile and shark. And we may add, that man is the only animal that has a prominent chin. This distinguishing character of the human skull, found in the proportion of the brain-case to the jaws when compared with the same in the inferior animals, the ingenious Camper devised the method of more accurately determining by means of what has been called the 'facial angle.' It consists in drawing one line from the most prominent part of the forehead to the sockets of the upper incisor teeth, and a second, which describes the ground plane of the cranium, through the external *meatus* of the ear and lower edge of the nose, and which, cutting the first on the upper jaw, forms with it a determinate angle; and it is evident that this angle will be greater in proportion to the development of the forehead and recession of the superior *maxilla*, less or more acute in proportion to the projection of the upper jaw and recession of the forehead. According to this mode of relative admeasurement, it appears that the facial angle in the European exceeds that in the negro; and it is worthy of notice that the Greek sculptors, who were careful to mark strongly, or even exaggerate those circumstances which peculiarly mark the human character, have often exceeded the right angle in the ideal anatomy of their deities, though at the same time with the discriminative taste which prevented them from exceeding the limit beyond which the form would have become a symptom of disease. It follows, then, that the size of the brain-case in man, proportionate to the development of the brain, indicates the predominance of this organ over those of the senses, which may be regarded as the measure of the subserviency of the animal to the outward excitants, and over the organs for the preparation of the food, the preponderance of which marks the subjugation of the creature to the mere animal needs, — that the predominant development of the cranium, I say, is the mark, symbol, and condition of man's characteristic excellence, as preeminently gifted with mind."

"If we compare the lower limbs of man with the hinder extremities of quadrupeds, we find the peculiar character and perfection of the former in their adaptation and appropriation to maintain the balance of the body in the erect posture. In some, indeed, the hinder limbs are so formed as to permit the creature to obtain for a time the free use of the fore extremities; but the endowment serves but to mark, as in the monkey, that it was intended for a climbing animal, and the extraordinary length and strength of the legs of the kangaroo show only its aptitude to leap. And if, in birds, the support of the body is effected by two legs, it leaves the interior extremities free only for the purpose of aiding in, and of executing, a different mode of locomotion. In man alone the lower extremities, providing wholly the means of support and progression, leave the upper limbs as instruments, the use of which is entirely at the choice of the agent. And, in aid of this purpose, we find in man the most perfect upper extremity. From the ape to the fish the different components diminish in number, development, and variety of motion. This is especially noticeable in the hand; which, in consequence of the length of the fingers, the number of articulations, and the multiplicity of their movements, especially in consequence of the capability of opposing the thumb to the fingers, becomes an instrument fitted for the most delicate and varied operations directed by the skill and intellect of man. Compare, in this respect, this flexible and modifiable apparatus with the single digit of the extremity of the horse, on the horny tip of which the weight of the animal (by an admirable mechanism indeed) is supported and carried; or with the abortive hand of the whale, sufficiently like the human to be so called, but retracted, enveloped in skin, and degenerated into a fin, that merely serves as an oar in propelling the animal through the water. It might be said, perhaps, that the hand of the monkey claims the praise of as great perfection as that of man; but the dwindled thumb marks its imperfection for handling and for touch: and the arms even of the anthropoeid orang-outan, lengthened to deformity, irresistibly prove their use to be little else than for grasping and climbing.

"In the contemplation of the human skeleton its most striking characteristic, however, and that which contradistinguishes it from the bony fabric of all other animals, is its adaptation to the erect position; an attribute not only peculiar to man, but without which his structure could not correspond to his spiritual endowments, since it is at once the need and symbol of a being raised above the servile condition of the mere animal nature.

"Thus the skull is poised, with only a slight preponderance anteriorly, at the top of the vertebral column; and a plumb-line dropped from the point of its support falls through the centre of gravity between the feet, which present the base of support to the whole towering fabric. We remark, however, that the supporting parts do not range with this line.

"The spine is bent like an italic *S*: it recedes at the chest, in order to give room to its cavity; and at the same time is harmoniously inflected forwards at the loins and neck, in order to facilitate its balance over the points of support; and it cannot be doubted that these curves contribute to the capability of bending and changing the position of the trunk, without endangering the loss of balance. But the balance of the body is also greatly aided by the breadth of the human pelvis, which supplying a broad base of support, permits the inclinations of the trunk without the necessity of altering the position of the lower limbs. The lateral breadth of the pelvis, however, throws the heads of the thigh bones, upon which the weight of the body is transmitted, to some distance on each side of the line that falls through the centre of gravity; and in order to provide a compensating adjustment, the thigh bones are placed obliquely, inclining towards each other; so that in the upright posture with the feet together they touch at the knees, and the weight is then received upon the heads of the leg bones or *tibiæ*, which stand perpendicularly under the centre of gravity: and these again are planted upon the arch of the foot or instep, on which the whole weight of the body securely rests. Then, in order to secure in the foot the requisite firmness in standing, we find that it is articulated with the leg at right angles, so that both the heel and toes touch the ground; and the joint is placed nearer the posterior than the anterior part of the foot, so as to increase the base of support in that direction towards which the body tends most to fall: besides which, the weight is here received on the inner side of the foot, where it is most arched, thereby offering not only the advantage of a strong support, but one which is highly elastic, yielding without injury in alighting upon the feet, and acting as a spring in progression. Thus the majestic column of the human form is raised and built up upon its pedestal; and the living pillar, readily maintaining its equipoise, bears aloft its capital, whilst the upper limbs are left free to adlibitive motion. Thus the place of the head, as the corporeal representative of that which perceives and wills; the disposition of the senses therein as the *media* of intelligence, and of the organs of speech as the interpreters of thought; and the arrangement of the upper limbs as instruments of volition, no longer subservient to mere animal needs, — all impress us with the conviction that even the skeleton cannot be intelligible to us without admitting that the human bodily frame was designed for the instrument and dwelling of a being contradistinguished from, and elevated above, all other animals —

> A creature, who not prone
> And brute as other creatures, but endued
> With sanctity of reason, might erect
> His stature, and upright, with front serene,
> Govern the rest, self knowing.

"Man alone is erect. It is to this posture that the body of a man owes the character, impressed on the whole frame, of its emancipation from subserviency to the mere animal needs, and becomes expressive of mind and of free and intelligent action. It will be seen that the lower limbs, answering the purposes of support and locomotion, have alone any obvious or necessitated utility; while the upper extremities are, in consequence, left at liberty, as the ready and facile instruments of his will. Hence too, the senses are best freed from their servitude to the bodily wants, and the countenance is raised as the expressive exponent of thoughts and feelings, which the mouth declares and interprets by words. And thus, as the stem bears the corolla, the head is carried on high as the most noble part of the frame which it surmounts; all the rest of the body seems as if intended to carry it; and when considered in its fitness for expression, it may be said to be the representative of the whole man.

"If principally connected with erect posture the body is admirable, and acquires its human character, we shall no less find, in directing our attention to the organs of motion in man, the aptitude and capabilities of a being designed for intelligent freedom. We find in man the organic structure adapted for the greatest variety of motion. It is true, indeed, that many of the Mammalia are so constituted as greatly to excel man in particular kinds of locomotion; but we shall in vain look for the same combination and mastery of his powers which the erect posture implies. The monkey climbs and jumps with a facility truly extraordinary; but it is with difficulty, or only for a short time, that he raises himself into the erect position. Dogs, horses, deer, excel man in swiftness; but they cannot climb nor walk erect. The otter, the beaver, and the seal swim well; but it is their only boast above creatures of their own kind. And whales, or other cetaceous animals, though admirably adapted for swimming, have no other means of locomotion. Man, on the other hand, stands and walks erect; runs, jumps, climbs, swims. Man alone can so modify his frame that it is in his power to waive the high privilege of

the harmony and balance of his faculties; and, by concentering his volition to any one property or perfection, we have reason to believe that he might equal or excel the beast most characterized by that perfection, — outrun the deer, outwrestle the bear, climb with the monkey. In short, man has the most modifiable organs of motion, and is most capable of subjugating them to his will, and of rendering them the instruments of his varied purposes.

"The capability of varied motion in man depends greatly upon the facility with which the different parts of the body, especially the limbs, move at the same time in opposite directions, — a power which not only permits variety of movement, and confers an aptitude of expressive action, but likewise gives pre-eminently a character of suppleness, ease, and freedom to the total motion. But it is the equipoise of his body, in connection with the erect position, which gives the unity to any totality of movement, and determines the attitude or carriage necessary to preserve its balance. In order to balance the body, whether at rest or in motion, it is necessary that the man should exert an incomparably greater number of muscles than the inferior animals; and for the same reason a far greater effort of his volition is required for adjusting the proportional action of each, and for combining and harmonizing the actions of all; in short, of all animals, man must be the master of his own body.

"It is further deserving of notice, that the inflections of the trunk, the motions of the limbs, and the play of the several joints, all tend to the circular and curvilineal in their movements; a circumstance which mainly tends to confer on human motion the character of beauty. And it may be safely affirmed that, under all the varieties of expressive movement, the very structure and mechanism of the body tend to reduce its motions to the form of the beautiful, or resolve them into grace; a fact of which we may convince ourselves in watching the sinuous movements of the dance, wherein, aided by the totality of motion in the dancer, they present a harmony by continuity — a problem of grace which is ever solving and ever beginning anew.

"Beauty of attitude and grace of carriage are, however, intimately connected with the maintenance and equipoise of the body. No attitude can be beautiful in which the idea of rest is not conveyed by that permanence and security which result from a perfectly felt balance. 'Grace of carriage requires not only a perfect freedom of motion, but also a firmness of step, arising from a constant bearing of the centre of gravity over the base of support.' (*Arnott's Physics*, p. 128.) It includes ease and security. And in both, whether it be motion becoming fixed as attitudes, or attitudes presenting themselves in the shaping flow of motion, beauty and grace reveal themselves in self-command, and in freedom made manifest by self-control. In short, look at the body in any position or attitude, in any of the incidental or casual forms arising out of the free and unconstrained movements of man healthy in frame and unshackled by conventional usages, and the truth will force itself on your conviction. Pass in review the ponderous strength of the Hercules, the agile Mercury, the graceful ease of the Antinous, the reclining Ilyssus, all the animated forms of the frieze of the Parthenon — whatever Greek art has signalized or modern genius realized; witness the sports of children, or go even to the wild denizens of the American forest, and proof will no longer be needed that grace and beauty are inherent in, not accidents of, the human body, as the fit instrument of human freedom and intelligence, and the translucent medium, as it were, of man's proper and spiritual being." (*Green's Vital Dynamics*, 1840, p. 60.)

The main points of internal anatomy in which man differs from or excels the lower animals are the following: — First of all in the magnitude of the brain, which is relatively greater than the spinal chord and nerves in him than in any other animal. This superiority is chiefly due to the great development of the hemispheres of the cerebrum, which are likewise characterized in man by the number and depth of the convolutions, by which the cineritious and vascular surface is augmented. The parts which are most evidently superadded to the human brain are the posterior lobes of the cerebrum, the corresponding horn of the lateral ventricle, and the lesser hippocampus.

Of the external senses, that of smell is the least developed; but both this and the other organs are well balanced, and in their organization most delicate and perfect. The two eyes are directed forward; and thus, though man does not see on two sides at once, like many quadrupeds, there is more unity in the result of his vision, and he can concentrate his attention more closely on the objects of his scrutiny. The external ear, having little mobility or extent, does not increase the intensity of sounds; notwithstanding which, Cuvier well remarks that man best distinguishes their intonation. So also with respect to the organ of smell: though most animals excel man in their power of scent for particular objects, there are none perhaps which can distinguish so many varieties of, or which are so uniformly affected by, unpleasant, odours. In the discrimination and delicacy of taste man has unquestionably the advantage over the lower animals; and in no species is the hand so framed, or the tactile extremities of the digits so expanded, or endowed with such an exquisitely sensitive and discriminative integument, as in man.

"Man," says Cuvier, "has a particular pre-eminence in his organs of voice: he is the only mammal that can articulate sounds; probably on account of the form of his mouth and the great mobility of his lips. Hence results his most valuable mode of communication; for of all signs that can be conveniently employed for the transmission of ideas, varied sounds are those which can be perceived at the greatest distance, and in most directions simultaneously."

The position of the heart, which rests obliquely on the diaphragm, and on which depends the absence of the azygos lobe of the right lung, and of the thoracic inferior cava, — both which exist in most of the inferior Mammalia, — relates to man's erect position.

The alimentary organs of man indicate his natural destination for a mixed diet of animal and vegetable substances; but the prehensile faculty of his hands, and the intelligence which governs its application, permitted the teeth to remain of such forms and proportions as might simply serve to divide and crush the food which the hands carry to the mouth. Thus the canine teeth, though present and with crowns shaped for piercing, do not exceed the adjoining teeth in size, and no interval in the dental series of one jaw is required to receive a produced tusk of the opposite jaw when the mouth is closed: thus the dental series in man is not only equable, but unbroken. The fore teeth are framed for dividing*; the back-teeth have flat and tuberculate crowns for bruising: the short and but moderately strong jaws hardly admit of the mastication of herbage, or the devouring of flesh that has not been previously prepared by cooking.

The organs of digestion conform with those of manducation; the stomach is simple; the intestinal canal of mean length; the small intestines are provided with numerous transverse folds of the secreting and absorbing mucous membrane, called *valvulæ conniventes*: the large intestines are well marked; they commence by a short and wide cæcum, provided with a long, slender, and vermiform appendage.

The period of gestation is nine months: in general there is only one child at a birth; twins are born once in about five hundred cases of parturition, and more than that number is extremely rare. The fœtus of seven months is eleven inches in length; that of nine months eighteen inches. Those which are born prior to the seventh month usually die. The first, or milk-teeth, begin to appear a few months after birth, commencing with the incisors; at two years the entire deciduous series, twenty in number, is attained. These are shed successively from about the seventh year, to be replaced by others. The eight deciduous incisors are succeeded by eight permanent ones; the four deciduous canines by four permanent ones; the eight deciduous molares by the eight bicuspides. Of the twelve true or posterior molars, which are permanent, there are four — one on each side of both jaws — that make their appearance at four years and a half; four more at nine years; the last four being frequently not cut until the twentieth year. The fœtus presents one fourth of the adult stature when born; it has attained one half of it at two years and a half, and three fourths at nine or ten years. Between the seventeeth and twenty-first years the growth almost entirely ceases. Man rarely exceeds six feet, and seldom remains under five. Woman is ordinarily some inches shorter. When the full stature is attained the body generally begins to increase in bulk: fat is accumulated in the cellular tissue; afterwards the solids become rigid; the fat is commonly absorbed; the before smoothly-filled integument falls in wrinkles; and old age arrives, with decrepitude, decay, and death. Man rarely lives beyond a hundred years; and most of the species, either from disease, accidents, or merely old age, perish before that term.

"The child," says Cuvier, "needs the assistance of its mother much longer than her milk; whence results an education intellectual as well as physical, and a durable mutual attachment. From the long period of infantile weakness results domestic subordination, and, consequently, the order of society at large; as the young persons which compose the new families continue to preserve with their parents those tender relations to which they have been so long accustomed. This disposition to mutual assistance multiplies to an almost unlimited extent those advantages previously derived by isolated man from his intelligence: it has assisted him to tame or repulse other animals, to defend himself from the effects of climate, and thus enabled him to cover the earth with his species. Circumstances, more or less favourable, have restrained the social condition within limited degrees, or

* The intermaxillary bones, in which the incisors are developed, are anchylosed to the maxillaries at an early period of fœtal existence.

have promoted its development. The glacial climates of the north of both continents, and the impenetrable forests of America, are still inhabited by the savage hunter or fisherman; the immense sandy or salt plains of Central Asia and Africa are covered with a pastoral people and innumerable herds: these half-civilized hordes assemble at the call of every enthusiastic chief, and overrun the cultivated countries that surround them, in which they establish themselves but to become enervated, and to be subjected in their turn to the next invaders. This is the true cause of that despotism which, in every age, has crushed the industry called forth under the fine climates of Persia, India, and China. Mild climates, soils naturally irrigated and rich in vegetables, are the natural cradles of agriculture and civilization; and when their position is such as to afford shelter from the incursions of barbarians, talents of every kind are mutually excited. Such were formerly (the first in Europe) Greece and Italy; and such is at present nearly all the happy portion of the earth's surface."

The influences of climate, and of the different habits and social conditions thence resulting, are associated with differences of form, stature, features, and colour of the skin; not greater, however, than the corresponding differences which indicate varieties of a species in the lower Mammalia: and accordingly naturalists have distinguished, and have characterized with more or less success, different races or varieties of man. As the races and varieties of the domesticated quadrupeds, so also those of the human species, blend imperceptibly with each other; and the absence of well-defined boundaries depends not only on the gradual subsidence and change of those physical causes which probably gave rise to the original varieties, but also to the faculty common to the individuals of different varieties of the same species to produce, by their union, individuals capable of propagating the intermediate variety. Hence has arisen the difficulty of defining the primary races of man, and the discrepancy which exists in the conclusions of those naturalists who have devoted the greatest attention to this important and most interesting branch of zoology. Cuvier considers that *three* varieties are eminently distinct, — the white, or *Caucasian;* the yellow, or *Mongolian;* the black, or *Æthiopian.*

"The Caucasian," he observes, "to which we belong, is distinguished by the beauty of the oval which forms the head; and it is this one which has given rise to the most civilized nations, — to those which have generally held the rest in subjection: it varies in complexion and in the colour of the hair.

"The Mongolian is known by his projecting cheekbones, flat visage, narrow and oblique eyebrows, scanty beard, and olive complexion. Great empires have been established by this race in China and Japan, and its conquests have sometimes extended to this side of the Great Desert; but its civilization has always remained stationary.

"The Negro or Æthiopian race is confined to the southward of the Atlas chain of mountains; its colour is black, its hair crisped, the cranium is contracted, and the nose flattened. The projecting muzzle and thick lips evidently approximate it to the apes: the hordes of which it is composed have always continued barbarous."

To the three primary races characterized by Cuvier Blumenbach adds the *Malayan* and *American* races. Of the Malays, however, Cuvier asks, "Can they be clearly distinguished from their neighbours on both sides, the Caucasian Indians and the Mongolian Chinese?" And with regard to the Americans, he states, "They have no precise or constant character which can entitle them to be considered as a particular race. Their copper-coloured complexion is not sufficient. Their general black hair and scanty beard would induce us to approximate them to the Mongols, if their defined features, their nose as projecting as ours, their large and open eyes, did not oppose such a theory, and correspond with the features of the European." Dr. Pritchard, however, considers that there are seven classes of nations which may be separated from each other by strongly marked lines.

The *first* class corresponds with Cuvier's Caucasian variety, but which Dr. Pritchard prefers to call *Iranian.*

The *second*, which he terms *Turanian*, is equivalent to the Mongolian variety.

The *third* class are the native American races, excluding the Esquimaux and some tribes which resemble them more than the majority of inhabitants of the new world.

The *fourth* class comprises only the Hottentot and Bushman races.

A *fifth* class includes the Negros.

The *sixth* class consists of the Papuans, or woolly-haired natives of Polynesia.

The *seventh* class includes the Alfourou and Australian races.

A study of the resemblances and differences of human speech in various regions and various ages has added much and will contribute more to the true knowledge and definition of the primitive races of the human species. It has already led to the establishment of the following families of languages: — The *Semitic*, to which belong the Hebrew, Arabic, Chaldean, Syrian, Phœnician, and Ethiopian; the *Indo-Europæan*, which includes Sanskrit, Persian, Greek, Latin, German, and Celtic; the *Monosyllabic* languages, as Chinese, Thibetan, Birman, Siamese; the *Polysynthetic* languages, a class including most of the American Indian dialects. The combination of zoological, anatomical, and glossological characters, is still wanting to establish the exact characters and limits of the human races.

MANATE'E. A herbivorous Cetacean, forming the type of a distinct genus, *Manatus.* See that word.

MANA'TUS. (Lat. manus, *a hand.*) The name given by Cuvier to a genus of his herbivorous Cetaceans, including the species usually called sea-cows. They have an oblong body, terminated by a lengthened oval fin; their grinders, which are eight on each side of both jaws, have square crowns marked by two transverse ridges. There are no incisors or canines in the adult; but when very young there are two very small pointed teeth in the intermaxillary bones, which soon disappear. Vestiges of nails are visible on the edge of their swimming paws, which they employ with some address in carrying their young; hence the comparison of these organs with hands, and the name *Manatee* and *Manatus* applied to the animal. There are two species of Manatee in America, and one in Africa; they inhabit the mouths of the great rivers, and browse on the herbage that clothes the banks.

MANCHINEEL. (Mancinella, the Spanish name.) A tree inhabiting the West India islands, and celebrated for its poisonous qualities. It is asserted that to sleep beneath its shade is to poison; and that the land-crabs found in the groves of manchineel become poisonous from feeding on its seeds. Although there is doubtless much exaggeration in these stories, no doubt exists of the deadly effects of manchineel juice when introduced into the system.

MANDA'MUS. In Law, a prerogative writ, in the form of a command, issuing from the Court of King's Bench, directed to any person, corporation, or inferior court of judicature within the king's dominions, requiring them to perform various duties. It is grounded on the suggestion of a party injured by the acts or omissions of such persons or bodies; and lies, for instance, to compel the admission or restoration of a party applying to an office or franchise which has been illegally withheld, for the production of public papers, to compel the holding of courts, &c.

MANDARI'N. The Portuguese term for a member of the official order of nobility in China. Mandarins are either civil or military: of the former there are nine classes, of the latter five. Although the mandarins are inferior in dignity to the higher class of nobility, whose dignity partakes of a personal character, they form the effective ministry and magistracy of the country. The Chinese equivalent of *mandarin* is *kouon*, which signifies literally *a public character.*

MA'NDIBLE, *Mandibula.* (Lat. mandibula, *a jaw.*) In Zoology, this term is applied to the lower jaw of mammals, and to both jaws of birds (except by Illiger, who restricts its appellation to the lower jaw in this class also). In insects it is applied to the upper or anterior pair of jaws.

MANDI'BULATES, *Mandibulata.* (Lat. mandibula, *a jaw.*) The name of a grand section of insects, including all those which preserve their organs of mastication in their last or perfect stage of metamorphosis.

MA'NDISC. The American name of the plant which is otherwise called *cassava*, and which is most extensively cultivated within the tropics of America, for the sake of the nutritive fæcula contained in its stems. It is the *Jatropha manihot* of botanists. The substance called tapioca is one of its products. In its raw state the whole plant is poisonous; but by the preparation and torrefaction of the fæcula the poisonous principle, which is volatile, is driven off.

MA'NDRAKE, or MANDRAGORA. A herb of fabulous character, concerning which there existed many singular superstitions. The herb mentioned in Genesis, ch. xxx., which our translation renders mandrake, was, probably, some flower or root to which common belief attached value as a philter. The mandrake of modern as well as classical superstition is a herb supposed to have a resemblance to the shape of a man. Those who tear it from the ground are obliged to do so with peculiar ceremonials (according to some, dogs must be employed to do so, which die instantly after): shrieks and groans are heard to issue from it, which have the power of injuring the unwary person who hears them. Its favourite habitat was believed to be the ground under a gallows on which a criminal was hanging. When plucked, it was said to be useful in conjurations, for the transformation of men or beasts; and was also believed to enable the

possessor to acquire riches at play, and to discover hidden treasures. (*Encyc. Metropol.*)

MA'NDREL. (Fr. mandrin.) In Machinery, a revolving shank to which turners affix their work in the lathe.

MA'NDRILL. (Eng. *man*, and *drill*.) A baboon. The name of the Catarrhine monkeys of the genus *Papio*, Cuv. They are the largest, most brutal, and ferocious of the baboons. The mandrill proper is the great blue-faced baboon of our menageries — *Simia mormon* and *maimon* of Linnæus. It is of a greyish-brown, inclining to olive above, with the cheeks blue and furrowed. The nose in the adult male becomes red, and even inclines to a fine scarlet at the end. It is difficult, says Cuvier, to imagine a more hideous or extraordinary animal. The male attains the size of a man, and is a terror to the negroes of Guinea and the other parts of Africa, of which this species is a native.

MANE'GE (Fr. from the Ital. maneggio), is used in England to signify either the art of horsemanship or of training horses.

MA'NES. A word of uncertain etymology, applied generally by the Romans to souls separated from the dead. There is some obscurity, however, about the precise meaning of this term. According to Apuleius, the Manes were originally called Lemures, and consisted of two classes, — the *Lares* and the *Larvæ;* the former of whom were the souls of those who had led virtuous lives, and the latter of those who had lived improperly; and, at a later period, the term *Manes* came to be a general designation for both. On the other hand, St. Augustin maintains that *Manes* was, from the first, a term applied to the spirits of deceased men when no definite opinion could be formed of their merits: — "Animas hominum dæmones esse, et ex hominibus fieri Lares, si meriti boni sint; Lemures sive Larvas, si mali; manes autem cum incertum est bonorum eos, sive malorum esse meritorum." In the month of February, annually, the Manes were propitiated at their sepulchres during twelve days. It was the duty of the pontifex maximus to see that proper ceremonies were observed. The stones in the Roman burial-places, and their funereal urns, were generally inscribed with the letters D. M. S. (Dis Manibus Sacrum).

MANGANE'SE. This name is generally given to a black mineral, originally described in the year 1774, by Scheele, as a peculiar earth; and which was afterwards shown by Gahn to be the oxide of a metallic substance which he called *magnesium*. This term, however, having been applied to the metallic base of magnesia, the word *manganese* has been adopted to designate the metal; and the ore above alluded to has been called black, or peroxide of, manganese. The metal itself has a specific gravity of about 8. It is grey, hard, brittle, and very difficult of fusion, and has not been applied to any use. The black oxide, on the contrary, is largely employed as a source of oxygen, and is especially important from the use which is made of it in the decomposition of common salt for the production of chlorine. Manganese may be represented by the equivalent 28; and the black oxide, being a compound of 1 atom of manganese and 2 of oxygen, has the equivalent 44 (28 + 16). There is also a protoxide of manganese, composed of 28 metal + 8 oxygen, which is the basis of the salts of this metal. When hydrate or carbonate of potassa, or nitre, are fused with peroxide of manganese in an open vessel, a dark-coloured compound is obtained, long known under the name of *chameleon mineral*, in consequence of its yielding in cold water a solution which is at first green, then blue, purple, red, brown, and ultimately deposits a brown powder, and becomes colourless. This substance has since been termed *manganate of potash*, and has been proved to contain a compound of 1 atom of manganese and 3 of oxygen, which has been called *manganic acid*, and is represented by the equivalent 52. In the pink solution, which is produced at once by the action of hot water, manganese exists in a still higher state of oxidizement, forming the *per-manganic acid;* in which 2 atoms of manganese are combined with 7 of oxygen. Both these compounds are very easy of decomposition. Some of the proto-salts of manganese have lately been used in calico-printing as the source of brown colours, and occasionally as deoxidizing agents.

MANGE. An eruptive disease which attacks several domestic animals, especially the dog. It is said to resemble the itch, and, like that disease, to be produced by a minute species of acarus which burrows beneath the cuticle. It is stated that the fluid discharged from the eruption of mange, in horses and dogs, has produced the itch upon the human skin. It is commonly produced by confinement and want of cleanliness, and bad or insufficient food.

MA'NGEL WURZEL. The root of the *Beta hybrida*. This German name is translated *root of scarcity;* the root being large, and used as a substitute for bread. It is cultivated for the food of cattle.

MA'NGER. The trough in which is placed the corn or other short food given to live stock, and more especially to horses. *See* RACK.

MA'NGER. The space near the hawse holes, bounded on the upper side by a partition across the bows, called the *manger board*, to receive the water while it enters the hawse holes and prevent it from flooding the deck.

MA'NGO (Mangos marum, in the Tamul language of India), is a very large fruit tree, inhabiting the tropical parts of Asia, throughout all which it is as extensively cultivated as the apple and pear trees are in Europe. Old specimens have been seen with a trunk from ten to fifteen feet in circumference. The fruit is something like a nectarine; but more compressed, longer, and more curved. It contains a large stone, covered with coarse fibres, which lose themselves in the succulent flesh. The wild and inferior varieties of this fruit taste so strongly of turpentine as to be wholly unfit for use by Europeans; but in the fine varieties this flavour is replaced by a rich sugary quality, which renders it very delicious. In this country the mango has rarely ripened its fruit; but it is common in the shops in a pickled state. The fruit of the *Mangifera Indica*, a tree cultivated in Asia, is also called *mango*.

MA'NGOSTEEN. The fruit of the *Garcinia mangostana*, growing in Java and the Molucca Islands: it is of the size of an orange, and of a delicious flavour.

MANGROVE (probably an abbreviation of *mangle* grove, the former being the Malay name), is a tree inhabiting the shores of the tropical parts of the world in either hemisphere, and well known to navigators on account of the dense groves it forms even down into the water itself. It belongs to the genus *Rhisophora*, and is principally remarkable for its seeds germinating before they leave the case in which they were generated on the branches. The young radicle grows downwards through the humid air till it reaches the mud, in which it fixes itself, and then the leaves and new stem unfold at the opposite end. The *white* mangrove, another shore plant of the tropics, is *Avicennia tomentosa*, quite a different genus from the genuine plants of that name.

MA'NIA. (Gr. μαινομαι, *I rage.*) Madness. It is defined to be delirium, unattended by fever, in which both judgment and memory are impaired, and the irritability of the body diminished so as to resist many morbid causes. There is a false perception of things, marked by incoherence or raving, and resentment of restraint. It is divided into melancholic and furious: the former marked by dejection of spirits; the latter by violent exertion of strength, malice to particular individuals, and repugnance to scenes and places before agreeable. Dissection has shown that in cases of madness there is usually effusion of water into the cavities of the brain, or appearances of previous inflammation of its membranes, or hardness of its substance, or peculiar thickness of the skull; and it has lately been stated that chemical analysis has shown an excess or deficiency of phosphorus in the composition of the brain in cases of madness and idiotcy.

MANICHE'ISTS. The followers of Manes, an oriental heretic of the 3d century, who, having been ordained a Christian presbyter, attempted to effect a combination between the religion which he was appointed to preach and the current philosophical systems of the East. He pursued herein the same course as the Valentinians, Basilidians, and many others, whose leading ideas may be denominated Gnostic. He maintained a dualism of principles governing the world, and a succession of dualisms generated from them, like the Gnostic æons. All things were effected by the combination or repulsion of the good and the bad; men had a double soul, good and evil; even their bodies were supposed to be formed the upper half by God, the lower by the Devil. The Old Testament was referred to the inspiration of the evil principle, the New to that of the good. In the letter, however, Manes proposed many alterations, and maintained also the authenticity of various apocryphal scriptures. A great part of his system related to cosmogony and psychology, in which fields of speculation he expatiated with the most arbitrary freedom. Like most other oriental systems, the Manichean heresy was celebrated alike for the austerities which it enjoined, and for the scandalous excesses which were attributed to its most zealous votaries. The charge of Manicheism, which in later times becomes scarcely intelligible, was frequently brought against the early reforming sects, such as the Albigenses, Waldenses, Picards, &c. (See Mosheim (transl.), ed. 1790, i. 303. &c.; Beausobre, *Hist. Critique de Manichée et du Manichéisme*, Amst. 1734; *Gieseler*, vol. i. 150. (transl.), ii. 151., iii. 340.; Milman, *Hist. of Christianity*, ii. 322.)

MANIFE'STO. In Politics, a declaration of motives publicly issued by a belligerent state, or by a general acting with full powers, previously to the commencement of hostilities. They are in the form of letters, with a superscription or heading addressed to the public in general, and signed with the name of the sovereign who sends them forth. The usage of issuing manifestos is said to date so far back as the 14th century. The term is probably derived from the Latin words "manifestum est," with which such documents usually commenced.

MA'NIOC. The Indian name of amylaceous products of the shrub called *Jatropha manihot*.

MANI'PULATION, in Chemistry, embraces the manual and mechanical operations of the laboratory; and in the delicate details of analysis, as well as in the exhibition of class experiments, great skill and practice in manipulation are required to ensure success. The processes of weighing, measuring, filtering, distilling, precipitating, dissolving, using the blowpipe, &c. all come within the meaning of manipulation. Mr. Faraday has published an excellent treatise upon this subject.

MANI'PULUS. (Lat. manus, *hand*.) In Roman Military Antiquities, a subdivision of the cohort: so called from the handful of grass, straw, &c. which formed its original standard. A maniple of triarii consisted of 60 men, one of hastati and principes of 120, when the number of the legion was 300. (See M. le Beau's Eighth Dissertation on the Roman Legion, *Mem. de l'Ac. des Inscr.* vol. xxxii.)

MA'NIS. The name of a genus of Edentate Mammals, singularly characterized by being covered with large, strong, imbricated, horny scales, like the Lacertine reptiles, and hence commonly called scaly lizards, and figuring in old zoological works among that class of animals. The manises, or pangolins, are, however, true warm-blooded mammals, and rank in the system of Cuvier among the Edentate order; of which they may be regarded as typical forms, being wholly destitute of teeth, and provided with a tongue of extraordinary length, with associated glands for preparing an abundance of adhesive lubricous mucous. By this organization they are peculiarly adapted to prey on ants, termites, &c.; and certain of their claws are extraordinarily developed, to enable them to break through the walls of the habitations of these social insects. The manises are confined to the warmest regions of Asia and Africa, where they play a corresponding part with that assigned to the true anteaters (*Myrecophagæ*) in South America.

MANITRUNK, *Manitruncus*, in Entomology, is a term given to the anterior segment of the trunk, in which the head inosculates, or on which it turns.

MA'NNA. (Syrian mano, *a gift;* it being a term applied to the food given by God to the children of Israel in the wilderness.) What we now call *manna* is a saccharine substance which exudes from the bark of the *Fraxinus ornus*, and some other species of ash, natives of the south of Europe, especially Sicily and Calabria. Manna is used in medicine as a mild aperient. It differs remarkably from common sugar in not being susceptible of vinous fermentation; so that, if mixed with common sugar and yeast, and subjected to the process of fermentation, the sugar becomes converted into alcohol, but the manna remains unaltered in the liquor. When manna is dissolved in boiling alcohol, the solution, as it cools, deposits it in flaky and acicular crystals, often arranged in concentric groups. Manna, thus purified, has been chemically designated by the term *mannite*.

Various opinions have been entertained respecting the precise nature of the manna on which the Israelites were sustained, and attempts have been made at various times to account for its miraculous appearance on natural causes; but, in our opinion, without any success. The Syriac word *mano* means a *gift*, referring to this circumstance, and is no doubt derived from the Hebrew *man-hu*, the Scripture explanation of which is certainly the best. The word asks a question, and signifies "*What is this?*" "for they wist not what it was." (Exodus, xvi. 15.) And if they did not know *then* "what it was," it is not likely we should know now. They could see that it was a little round grain, or something like a grain, of the size of coriander-seed, and white as the hoar frost on the ground; but it had no component parts such as they could describe. And even admitting, as has been frequently maintained, that it exuded from the bark of the ash, or some other tree, it is incredible that it could be supplied in such abundance in the deserts of Arabia as to give sustenance to 500,000 Israelites for 40 years, without the miraculous intervention of Providence.

MA'NNER. (Fr. maniere.) In the Fine Arts, a peculiarity of treating a subject, or of executing it, by which individual artists are distinguished: the latter arising out of a particular mode of using the media and implements of art, the former out of a singular method of observing nature. (See *Sir J. Reynolds's Sixth Discourse.*)

MAN-OF-WAR, MERCHANT-MAN. The common terms for ship-of-war, merchant-ship.

MANO'METER, or MA'NOSCOPE. (Gr. μανος, *rare*, and μετρον, *a measure*, or σκοπεω, *I view*.) An instrument for measuring the *density* of the air, or rather its *elastic force*, to which the density is supposed to be proportional. *See* PNEUMATICS.

MA'NOR (Lat. maneo, *I reside;* from the residence of the lord), signifies a district subject to the jurisdiction of a court baron. In the feudal ages, a grant of lands from the king carried with it a right of dominion; and the grantee or baron had power to make laws, and hold a court of justice for his dependents within the territory, which was called a manor. The baron might also, by subinfeudation, parcel out the land so granted to others, to hold of him, as he held of the king, by military service or other tenure. These again further subdivided the land by grants to others, and so on, increasing manors by this process ad infinitum. The services due to the lord of the fee were, in consequence, very negligently performed; and, to meet this inconvenience, the statute of Ed. I., called Quia Emptores, was passed, which enacted that the buyers of lands should hold them by the same services, and of the same lord, as they were before held by when in the hands of the seller. This put a stop to the increase of manors; and every manor, therefore, now in existence, must have existed in the time of Ed. I., and before the enactment above mentioned.

MA'NSARD ROOF. (So called from the name of its inventor, a celebrated architect.) In Architecture, the same as *curb roof*, which see.

MA'NTELET. A moveable parapet, constructed of boards covered with tin, iron, or leather, to serve as a protection to the miners in carrying a sap or a trench towards a besieged place. Mantelets are of various forms, adapted to the peculiar circumstances of the approach.

MA'NTIS. (Gr. μαντις; applied by Theocritus (*Idyl.* x. 18.) to the cicada.) A Linnæan genus of Orthopterous insects, characterized by having the head exposed, and the body narrow and elongated; the palpi short, and terminating in a point; the ligula quadrifid; the tarsi five-jointed, and the wings simply plaited longitudinally, and not ray-wise, like a fan. The true mantises,—sometimes called *praying insects*, on account of the position of the anterior pair of legs, which differ from the rest,—are found only in tropical and temperate climates: they are diurnal, and remain almost stationary on plants and trees; frequently resembling, in a remarkable degree, their leaves and branches in both the form and colour of the wings and body, and thus they deceive the smaller insects on which they prey. Their eggs are usually enclosed in a capsule formed of some glutinous substance, which hardens by exposure to the air, and is divided internally into several cells. It is curious to trace the correspondence with the vegetable kingdom already noticed in the wings and body continued into the form of the egg-capsules, which in many species closely resemble a seed receptacle of a plant, presenting regularly disposed ridges and angles, or even being bristled with little spines. The female attaches it by an adhesive secretion generally to the stem of a plant.

A second group of mantises, characterized by having the anterior legs like the following ones, now form a distinct subgenus, *Spectrum*, and are generally called *spectre insects:* they feed exclusively on vegetables, of which they singularly resemble the dried twigs. The progress of entomology has required further subdivisions of both the above groups.

MANTI'SSA. The decimal part of a logarithm is sometimes called the *mantissa* of the significant digits, the integral part being the *characteristic*. Thus, in log. $900 = 2{\cdot}95424$, the characteristic of the logarithm of the number is 2, and 95424 is the mantissa, which belongs equally to the numbers 9, 90, 900, ·9, &c.

MA'NTLE. (Fr. manteau.) In Architecture, the piece lying horizontally across from one jamb of a chimney to the other. In Malacology, the external fold of the skin of the mollusks.

MA'NUAL (Lat. manus, *the hand*), was applied originally to the Roman Catholic service book, from its convenient size (being such as might be carried in the hand); but it now signifies any small work used chiefly for the purpose of reference.

MANUFA'CTURE. (Lat. manus, *a hand*, and facio, *I make*.) In Political Economy, a term employed to designate the changes or modifications made by art and industry in the form or substance of material articles, in the view of rendering them capable of satisfying some want or desire of man. Hence the perfection of manufacturing consists in the being able to effect the wished-for changes in the raw material with the least expenditure of labour, or at the least cost.

With the exception of fishing, hunting, mining, and such branches of industry as have for their object to obtain possession of material products in the state in which they are fashioned by nature, all other branches may, in fact, be comprised under the term manufacture. Generally, indeed, it is applied only to those departments of industry in which the raw material is fashioned into desirable articles by art and labour without the aid of the soil. But there is no really good foundation for any such limitation; which, unless explained, is apt to make it be supposed that businesses which are substantially identical not only differ from, but are opposed to, each other. It is obvious, indeed, on the slightest consideration, that agriculture in nothing but a manufacture; for the business of the agriculturist is so to dispose of the soil, seed, manure, and other materials, that they may supply him with other and more desirable products. Manufacturing industry consists, in fact, in

the *application of art, science, and labour to bring about certain changes or modifications of already existing materials;* and its varieties depend wholly on the modes in which this application is made. The manufacture of any particular article usually derives its name from the raw material manufactured, modified, or wrought up into a new shape. Thus the terms woollen, cotton, and hardware manufacture, mean the working up of wool, cotton, or metals into useful or desirable articles; shipbuilding is the manufacture of timber and iron into ships; agriculture (*ager* and *colo*) is the production of corn, beef, and other products, by the adaptation of the soil and the vegetative powers of nature to their manufacture, and so on. The knowledge of the means by which art and labour may be most successfully employed in each of these departments forms the peculiar business of the woollen, cotton, and hardware manufacturers, ship-builders, agriculturists, &c.

It would far exceed our limits to attempt to enter into any details with respect to the application of labour in the separate departments of manufacturing industry; but considering the vast importance of manufactures to mankind, and especially to the British nation, we may, perhaps, be excused for endeavouring shortly to state some of those conditions and circumstances that seem, in a general point of view, most essential to success in manufactures.

These are partly of a moral and political, and partly of a physical description. Of the former class, the most important seem to be, the security and free disposal of property; the absence of monopolies, and the non-interference of government in industrious undertakings; the diffusion of knowledge amongst the people; the cordial reception of foreigners; and the emulation and energy inspired by inequality of fortune, and by the gradual increase of taxation. Among the more prominent of the physical circumstances conducive to the progress of manufactures are supplies of the raw materials to be manufactured, with the command of power; that is, of coals, waterfalls, &c. A good deal, also, of the progress of manufactures seems to depend on the advantageous situation of a country for commerce, and on the nature of its climate. We shall briefly notice some of the more prominent of these circumstances.

1. *Moral Circumstances contributing to the Progress of Manufactures.*—1. It is unnecessary to take up the reader's time by enlarging on the necessity of security, and of the free disposal of property, to success in manufacturing industry, or indeed in any laborious undertaking. Without security there can be neither industry nor invention. No man will engage in any employment, or exert either his bodily or mental powers, unless he be well convinced that he will be allowed to reap all the advantages accruing from his labour, skill, or genius. Any doubt as to this is sure to paralyse his exertions. And if, owing to the weakness or ignorance of government, the prevalence of a revolutionary spirit, or any other cause, the security of property were materially impaired, all sorts of industrious undertakings that did not promise an immediate return would be forthwith abandoned; and every person possessed of property would endeavour to convey it out of the country. The want of security is, in fact, the greatest of public calamities. In its absence we find nothing but the most abject poverty and barbarism; and, supposing other things to be equal, the wealth and civilization of nations will be pretty nearly proportioned to the security of property they respectively enjoy. Every other circumstance conducive to the advancement of industry may exist in a country; but, without security, these can be of no material service. A high degree of security will compensate for many deficiencies, but nothing can make up for its want; it is a *sine quâ non* of manufacturing and national prosperity.

2. The absence of monopolies, and the non-interference of government in industrious undertakings, undoubtedly conduce in no ordinary degree to the progress of industry. Every man is always exerting himself to find out how he may best extend his command over the necessaries and conveniences of life; and sound policy requires that he should, so long as he does not interfere with the rights and privileges of others, be allowed to pursue his own interest in his own way. That individuals are, generally speaking, the best judges of what is most beneficial for themselves, is now universally admitted to be the only principle that can be safely relied on. It is the duty of governments to preserve order; to prevent one individual from injuring another; to maintain, in short, the equal rights and privileges of all. But it is not possible for them to go one step further without receding from the principle of non-interference, and laying themselves open to the charge of acting partially by some and unjustly by others.

The most comprehensive experience corroborates the truth of this statement. Since the passing of the famous act of James I. in 1624, for the abolition of monopolies, full scope has been given in Great Britain to the competition of the home producers; and though the various resources of talent and genius have not been so fully perhaps, or at least so early developed, as they would have been had there been no restrictions on our intercourse with foreigners, they have been stimulated in a degree unknown in most other countries. France, previously to the Revolution, was divided into provinces, having each peculiar privileges and separate codes of revenue laws; and, in consequence, the intercourse between them was subject to the most oppressive restrictions. In Germany and Spain the same miserable system prevailed; so that they were not only deprived of the freedom of foreign, but even of internal commerce. The inhabitants of each province being in a great measure isolated from the rest, there was comparatively little competition; and, instead of invention and active exertion, there was nothing but routine and sluggish indifference. Holland and the United States have been almost the only countries that have enjoyed the same degree of internal freedom as Great Britain; and the former, notwithstanding the unfavourable physical circumstances under which she is placed, has long been, and still is, the richest country in Europe; while the latter, whose condition is in other respects more favourable, is advancing with giant steps in the career of improvement.

It is sometimes said that restrictions on industry and commerce cannot be so injurious as has been represented, seeing the progress we have made notwithstanding they have always existed amongst us. The previous details show the weight to be attached to this allegation. The restrictions referred to have been confined to some branches of foreign trade; and, luckily, the freedom allowed to all sorts of industry at home would have insured our advance even had our foreign trade been a good deal more fettered and restrained than it actually has been. But to imagine, as many have done, that these restrictions contributed to accelerate our progress, is the climax of folly. Their influence is, in every case, distinctly and completely the reverse; but though considerable, even in Great Britain, it has been insufficient to countervail the advantages resulting from the freedom we otherwise enjoyed.

3. The ability to read, and the diffusion of instruction among all ranks and orders of the people by the general circulation of books and journals, the establishment of mechanics' institutes, &c., have had a material influence over the advancement of arts and industry. They have had the double advantage of multiplying the means and chances of improvement, and of preventing any invention or discovery, when made, from being lost or engrossed by a few. An uninstructed people, though surrounded by all the means and capacities required for the manufacture of commodities and the accumulation of riches, being unable to apply them, are necessarily poor and destitute; but an intelligent people, though placed in a comparatively unfavourable situation, never fail, by availing themselves of the powers and energies of nature, and making them subservient to their purposes, to attain to distinction as manufacturers, and so become rich and prosperous. That "knowledge is power" is true in manufactures as well as in morals. The more familiar our acquaintance with and the more complete our command over natural agents, the greater, of course, must be our ability to modify rude products, and to make them minister to our wants and the gratification of our desires. In tracing the causes of our success in manufactures and industry, it is not possible to appropriate to each circumstance the portion belonging to it of a result which is the joint effect of the whole; but if this could be done, it would be found that no inconsiderable share is fairly ascribable to the extraordinary diffusion amongst us of scientific information.

4. For a lengthened period the reception given to foreigners in England was any thing but cordial. In most countries, indeed, not in an advanced state of civilization, strangers are uniformly the objects of popular dislike; and this feeling seems at one time to have prevailed quite as much in England as any where else. But notwithstanding the various legal disabilities laid on foreigners, and the ill-treatment they often experienced, their settlement here has been productive of the most advantageous results. The Flemings, invited over and protected by Edward III., gave the first great impulse to the woollen manufacture; and the immigrations from the Low Countries during the persecutions of the Duke of Alva, and from France subsequently to the revocation of the Edict of Nantes, materially forwarded our commerce and many branches of manufactures. During the last century the prejudice against aliens lost much of its force; and several of the disabilities under which they formerly laboured have been removed. But in all that respects the treatment of foreigners, our policy has been less liberal and enlightened than that of the Dutch. In Holland they have always been received with open arms; and a short residence in the country, and a small payment to the state, have entitled them to all the privileges

enjoyed by natives. The highest authorities agree that this was one of the main causes of the extraordinary progress made by the republic in commerce and wealth. "It has always been our constant policy to make Holland a perpetual, safe, and secure asylum for all persecuted and oppressed strangers; no alliance, no treaty, no regard for nor any solicitation of any potentate whatever, has at any time been able to weaken or destroy, or make the state recede from protecting, those who have fled to it for their own security and self-preservation. Throughout the whole course of all the persecutions and oppressions that have occurred in other countries, the steady adherence of the republic to this fundamental law has been the cause that many people have not only fled thither for refuge, with their whole stock in ready cash, and their most valuable effects, but have also settled and established many trades, fabrics, manufactures, arts, and sciences, in this country, notwithstanding the first materials for the said fabrics and manufactures were almost wholly wanting in it, and not to be procured but at a great expense from foreign parts." (Memorial by Dutch Merchants, presented to the Prince of Orange in 1751.)

5. We incline to think that the great inequality of fortune that has always prevailed in this country has powerfully contributed to excite a spirit of invention and industry among the less opulent classes. It is not always because a man is absolutely poor that he is perseveringly industrious and economical; he may have already amassed considerable wealth, but he continues with unabated energy to avail himself of every means by which he may hope to add to his fortune, that he may place himself on a level with the great landed proprietors, and those who give the tone to society in all that regards expense. No successful manufacturer or merchant ever considers that he has enough till he be able to live in something like the same style as the most opulent landlords. Those immediately below the highest become, as it were, a standard, to which the class next to them endeavour to elevate themselves; the impulse extending, in this way, to the very lowest classes, individuals belonging to which are always raising themselves by industry, address, and good fortune to the highest places in society. Had there been less inequality of fortune amongst us, there would have been less emulation, and industry would not have been so successfully prosecuted. It is true that the desire to emulate the great and the affluent, by embarking in a lavish course of expenditure, is often prematurely indulged in, and carried to a culpable excess; but the evils thence arising make but a trifling deduction from the beneficial influence of that powerful stimulus which it gives to the inventive faculties, and to that desire to improve our condition and to mount in the scale of society which is the source of all that is great and elevated. Hence we should disapprove of any system, which, like that of the law of equal inheritance established in France, had any tendency artificially to equalize fortunes. To the absence of any such law, and the prevalence of customs of a totally different character, we are inclined to attribute a considerable portion of our superior manufactures, wealth, and industry.

6. We are also disposed to believe, how paradoxical soever such a notion may appear, that the taxation to which we are subject has hitherto at least been favourable to the progress of industry. It is not enough that a man has the means of rising in the world within his command: he must be placed in such a situation that unless he avail himself of them, and put forth all his energies, he will be cast down to a lower station. Now this is what our taxation has effected: to the desire of rising in the world, implanted in the breast of every man, it superadded the fear of being thrown down to a lower place in society; and the two principles combined produced results that could not have been produced by either separately. Had taxation been carried beyond due bounds, it would not have had this effect. But though considerable, its increase was not such as to make the contributors despair of being able to meet the sacrifices it imposed by increased skill and economy; and the efforts they made in this view were far more than sufficient for their object; and consequently occasioned a large addition to the public industry and wealth, that would not otherwise have existed.

II. *Physical Circumstances contributing to the Progress of Manufactures.* — 1. Supplies of the raw material may be classed among the more prominent of this description of circumstances. Those who reflect on the value and importance of our manufactures of wool; of the useful metals, such as iron, tin, lead, copper, &c.; of leather, flax, and so on,— will readily admit that our success in them has been materially facilitated by our possessing abundant supplies of the raw material. It is of less consequence, when the material of a manufacture possesses considerable value in small bulk, whether it be furnished from native sources or be imported from abroad; though even in that case, the advantage of having an internal supply, which cannot be withdrawn through the jealousy or hostility of others, is far from immaterial. But no nation can make any considerable progress in the manufacture of bulky and heavy articles, the conveyance of which to a distance necessarily occasions a large expense, unless she have supplies of the raw material within herself. Had we been destitute of iron ore, lead, and tin, we could never have distinguished ourselves by the magnitude and value of our manufactures of these articles; and any one who reflects on the signal advantage resulting to every branch of manufacturing industry from being able to procure abundant supplies of iron at the cheapest rate, will be convinced that we are under any thing but slight obligations to our exhaustless stores of this mineral.

2. But of all the physical circumstances that have contributed to our extraordinary progress in manufactures and industry, none have had so much influence as our possession of the most valuable coal mines. These have conferred advantages on us, not enjoyed in an equal degree by any other country. Our extraordinary success in the manufacture of iron, copper, &c. is not owing so much to our possessing the ores, as to our possessing the coal by the aid of which they have been smelted and refined. The paramount importance of coal as a manufacturing agent has, however, been principally manifested since the invention of the steam-engine. Without a cheap and abundant supply of fuel, the engine, as now constructed, would be of comparatively little use. It is, as it were, the hands by which the most gigantic results are effected; but coal is the muscle by which the hands are set in motion, and without which their all but illimitable power and dexterity could not be called into action, or made subservient to any useful purpose. Our coal mines may thus, in truth, be regarded as vast magazines of hoarded or warehoused power; and unless some such radical change should be made on the steam-engine as should very decidedly lessen the quantity of fuel required to keep it in motion, or some equally serviceable machine, but moved by different means, be introduced, it is not at all likely that any nation should come into successful competition with us in those departments of manufacturing industry in which steam-engines, or machinery moved by steam, may be advantageously employed.

3. The advantageous situation of a country for commerce, and the nature of its climate, have also a powerful influence over manufacturing industry. Owing to the facilities afforded by the insular situation of Great Britain for maintaining an intercourse with all parts of the world, our manufacturers have been able to obtain supplies of foreign raw materials on the easiest terms, and to forward their own products wherever there was a demand for them. Had we occupied a central or internal situation in any quarter of the world, our facilities for dealing with foreigners being so much the less, our progress would have been comparatively slow; but being surrounded on all sides by the sea, that is, by the great highway of nations, we have been able to deal with the most distant as well as with the nearest people, and to profit by the peculiar capacities of production enjoyed by each. Under such circumstances, it would have been singular had we not shot ahead of most of our competitors in the race of improvement; and it will require some powerful counteracting agency to neutralize or overcome these advantages.

4. Our climate is peculiarly favourable for all sorts of exertion and enterprise: without being too severe, it is sufficiently so to render comfortable clothing and lodging indispensable; and consequently gives rise to wants that are either unknown, or less sensibly felt, in more genial regions. Its inequality too, by requiring incessant care and attention on the part of the husbandmen, or manufacturers of corn, makes them vigilant and active, as well as industrious; and the qualities that are thus naturally impressed on this great class are, through their example, universally diffused.

The author of a valuable article on English statistics in the *Edinburgh Encyclopædia*, when enumerating the causes of our extraordinary success in manufactures, lays the greatest stress on the superiority of our machinery, the magnitude of our capital, and the extent to which the division of labour is carried amongst us. But this is to mistake effects for causes. These, in fact, are the means and instruments by which manufacturing industry is immediately carried on; and the real inquiry is, what are the circumstances that have rendered us so abundantly supplied with these means? We have endeavoured briefly to answer this inquiry, by stating what appear to be the most prominent causes of that extraordinary accumulation of capital, and of that universal employment of improved and powerful machinery and subdivided labour, which mark our eminence as a manufacturing people. Still, however, we are inclined to think that a good deal must in these matters be ascribed to chance, or to some lucky contingency, that could not *à priori* be looked for. Had Hargreaves, Arkwright, Watt, or Wedgwood not existed, or been born abroad, it is impossible to say how much it might have affected the state of industry here; but there seem to be sufficient grounds for thinking that it

would have been, at this moment, materially different from what it actually is. A good deal, too, depends on priority. A country, town, or district, that has already established and made a considerable progress in any manufacture, acquires, in consequence, an advantage that may enable it successfully to contend with competitors placed under what are naturally more favourable circumstances; its merchants are already in possession of the markets; its inhabitants, being trained to the business, have acquired that peculiar sleight of hand that is necessary to form expert workmen; and they are in this way frequently able to preserve their ascendency for a lengthened period, and sometimes even to drive those from the field who have a preponderance of natural advantages on their side.

It seems to be the peculiar good fortune of England that, as respects all the great branches of manufacture, she has at once the advantages of priority and of acquired skill and dexterity on her side, as well as the natural advantages already noticed of abundant supplies of the raw material, of inexhaustible beds of coal, and of situation. Cotton is not an exception; for though the raw material be the product of other countries, the freight upon it is not very considerable, and is but a trifling deduction from the other circumstances that seem to insure our superiority in this department. To excel in machine-making is to excel in what is certainly the most important branch of manufacturing industry. Superiority in any single branch, except this, may exist simultaneously with great inferiority in many others; but eminence in the manufacture of machinery is almost sure to lead to eminence in every other department.

Considerable, though not, as it appears to us, too much stress, has been laid on the practice generally adopted in Great Britain, of paying workmen, wherever it is practicable, by the piece, or by the work done, and not by the day. This system gives the workmen an interest in being industrious, and makes them exert themselves to execute the greatest quantity of work in the least space of time; and in consequence of its prevalence, this practice materially influences even the day labourers, who, to avoid invidious comparisons, make exertions unknown in other countries. Hence a given number of hands in Great Britain perform much more work than is executed by the same number of hands almost any where else; in fact, if we regard wages in their proper light, that is, if we look upon them as a compensation for work done, and not for the time spent in doing it, they will, we believe, be found to be cheaper in Great Britain than in most other countries. (For farther particulars, see the section on Manufactures in the *Statistical Account of the British Empire*, whence this article has been partly abstracted.)

MANUMI'SSION, or ENFRANCHISEMENT. (Lat. manus, and mitto, *I send away.*) The grant of liberty to a slave. Ancient charters containing such grants were frequently termed chartæ ingenuitatis. (See a law of William the Conqueror, *Lamb. Archai.* 126.) The term manumission is derived from a practice adopted by the ancient Romans in enfranchising their slaves. The master seized the hand of the slave, and dismissed him with the words "hunc hominem liberum esse volo." Among the Romans there were two classes of manumission, called perfect and imperfect; the former of which were effected in three different ways. The enfranchisement was perfect — 1. Per censum; by which the name of the slave was, at the master's request, placed in the register of free citizens. 2. Per vindictam; when the slave was led before the prætor, and, the master having demanded his liberty, that magistrate laid the vindicta (or rod of office) on his head, with the words "aio te liberum esse more quiritium." 3. Per testamentum; by will. It was imperfect when the slave was enfranchised at private entertainments, or by letter. *See* CLIENT.

MANU'RES. Substances added to the soil, with a view of accelerating vegetation, and increasing the production of the crops. Animal, vegetable, and mineral substances are used for this purpose. Decomposing animal matter of any kind forms one of the most powerful manures, and in many instances accelerates the decay and decomposition of inert vegetable matters mixed with it; as in the mixture of dung and straw which forms the common offal of stables. All animal excrements are also powerful manures, and, when duly applied to the soil, soon exhibit their influence by the luxuriance of the crop. It, however, often happens in respect to esculent vegetables that their quality is deteriorated, and that they acquire a coarse and rank flavour, if over-manured; as is the case with much of the produce of the market-gardens near London, where, in consequence of the vicinity of the metropolis, manure is abundant, and luxuriant and fine-looking vegetables in great request for the table.

In all cases where animal manures are used care should be taken that they are brought into action upon the soil as soon as they begin to decompose, or as soon as possible afterwards, and not suffered to rot, and exhale their best constituent parts whilst lying in the farmyard. The drainings and the exhalations of a common dung-heap contain its most effective ingredients; and these are often suffered to go to waste, or to contaminate the air and collect in pools of filth. The fresh and the old manure of this decomposition are known to farmers under the terms *long* and *short* dung: the advantages and economy of the former, when properly applied, cannot be doubted. Those animal manures which are slow of decomposition are most durable, and generally most effective in their operation. Of these the best is ground bones, the animal part of which is very gradually dissolved out by moisture; so that their effect is long-continued, and their earthy matter is also probably beneficial, at least to many crops. Vegetable manures are often very effective, especially as in the case of ploughing in a green crop, where all the soluble matters are brought into action; and inert vegetable substances may be rendered active by mixture with those which easily putrefy, or with animal matter. Some vegetables, such as cabbages and many other cruciform plants, approximate to animal matter in their composition, and are proportionately good manures. Mineral manures act in two ways: either by their causticity, as is the case with quicklime, by which they decompose most organic bodies, such as roots, fibres, &c., and render them soluble and nutritious to the growing crop; or they alter the texture of the soil. Thus, sand may be called a manure for clayey lands, and clay and loam for those that are sandy. Upon the same principle, stiff soils are improved by paring and burning, by which a superficial sandiness is produced, and the texture of the soil rendered more appropriate for vegetation.

MA'NUSCRIPTS. (Lat. manu scriptum, *written by the hand.*) Literally writings of any kind, whether on paper or any other material, in contradistinction to such as are printed. Books were generally written upon vellum, after the papyrus used in classical times had become obsolete, until the general introduction of paper made from rags, about the 15th century after Christ; and the finest and whitest vellum is generally indicative of great age in a manuscript. The dearness of this material gave rise to the practice of using old manuscript books on which the writing had been erased (*see* PALIMPSEST), and also to that of abbreviations. These were carried to excess in the 12th century, and from that time until the invention of printing; and for a long period subsequent to that invention abbreviations were still in common use: in Greek printing they were usual until within the last fifty years. Of Latin MSS. those prior to the reign of Charlemagne (A. D. 800) are considered ancient. Manuscripts of the early classical age were written on sheets rolled together. *Illuminated manuscripts* are such as are embellished with ornaments, drawings, emblematical figures, &c. illustrative of the text. This practice was introduced at a very early period; for we find the works of Varro, Pomponius Atticus, and others adorned by illuminations. But it was chiefly employed in the breviaries and prayer book of the early Christian church. The colours most employed for this purpose were gold and azure. Illuminations were in a high state of perfection between the 5th and 10th centuries; after which they seem to have partaken of the barbarism of the middle ages, which threw their chilling influence over every description of art. On the revival of the arts in the 15th and 16th centuries many excellent performances were produced; but the art did not take deep root, and we believe the last specimen of illumination executed in this country was Cardinal Wolsey's *Lectionary*, at Christ Church, Oxford. *See* CODEX, DIPLOMATICS, PALÆOGRAPHY.

MAP. (Lat. mappa.) A delineation of some portion of the surface of the sphere (terrestrial or celestial) on a plane. Terrestrial maps are *geographic* or *hydrographic*, according as they denote a portion of the land or of the sea; the latter, however, are usually called *charts.* (*See* CHART.) A map representing a small extent of country is called a *topographical map*.

Terrestrial Maps. — The object of a terrestrial map is to exhibit the boundaries of countries and the relative positions of their several parts. A perfect representation of a country should present all its parts, not only in their true relative positions, but also in their just proportions. This may be accurately done on a globe; but as the earth's surface is spherical, it is impossible to represent any considerable portion of it on a plane so that the distances of places shall retain the same proportions which they have on the sphere, and geographers have accordingly had recourse to various methods of delineation, all of which have their peculiar advantages in particular cases.

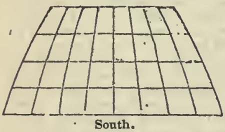
One method is to represent the points and lines of the sphere according to the rules of perspective, or as they would appear to the eye, having some assigned position relatively to the sphere and the plane of representation. This method gives rise to the different modes of *projecting* the sphere, of which the three principal are the orthographic, the stereographic, and the central. The method of projection answers very well when the surface to be represented is small, and the eye is placed perpendicularly over it; but when it embraces a considerable

portion of the sphere, the parts near the extremities of the map are much distorted. See PROJECTION.

A second method is to suppose the surface to be represented to be a portion of the surface of a cone, whose vertex is somewhere in the polar axis produced, and which either touches the sphere at the middle latitude of the surface to be represented, or falls within the sphere at the middle latitude, and without it at the extreme parallels. The conical surface is then supposed to be developed on a plane (which it admits of being); whence this method is called the method of development. Of this method there are various modifications: as that of Murdoch, who supposes the side of the cone to be parallel to the tangent of the meridian at the middle latitude, but to penetrate the surface of the sphere between the middle latitude and the extremities of the projected arc; that of De Lisle, who assumed the cone such as to intersect the sphere in the two parallels equally distant from the extreme and middle latitudes; that of Euler, who placed the apex of the cone at a determinate distance beyond the pole.

A third method is to lay down the points on the map according to some assumed mathematical law, the condition to be fulfilled being that the parts of the spherical surface to be represented, and their representations on the map, shall be similar in their small elements. Of such methods the best known is *Mercator's Chart* (which, however, may be produced also by development), in which the meridians are equidistant parallel straight lines, and the parallels of latitude are also straight lines perpendicular to the meridians; but of which the distances from each other increase in going from the equator in such a proportion as always to show the true bearings of places from one another. See MERCATOR'S CHART.

Celestial Maps. — For the construction of his maps of the stars, the astronomer Flamsteed adopted the following method: — All the parallels on the sphere are represented by straight lines, and likewise one of the meridians; namely, that which passes through the middle of the map, as in the annexed diagram. The parallels which are all perpendicular to this meridian have the same relative lengths as on the sphere, and consequently the degrees of longitude are represented in their just proportions; that is, are proportional to the cosine of the latitude. If, therefore, the parallels be each divided into the same number of equal parts, a curve line drawn through the points of division will represent the meridians. By this method any distance in the direction of the parallels is equal to the corresponding distance on the sphere; but it is evident that the map is much distorted towards the extremities, in consequence of the oblique directions of the meridians. Flamsteed's method is sometimes used in geography for representing countries which lie on both sides of the equator, in which case the distortion is less. A modification of it, which consists in substituting arcs of circles for the straight lines representing the meridians, whereby their obliquity is diminished, is extensively employed in the construction of maps. The Society for the Diffusion of Useful Knowledge has adopted the gnomonic projection for laying down their maps of the stars.



For details respecting the general construction of maps, we refer the reader to the work of Mr. Jamieson on the subject; *Malte Brun's Geography; Malte Brun's and Balbi's Systems of Geography Abridged; Murray's Encyclopedia of Geography; De Morgan's Explanation of the Gnomonic Projection of the Sphere;* and particularly the *Traité de Topographie d'Arpentage et de Nivellement* of Puissant.

MARANA'THA. (Syr.) A form of anathematizing among the Jews, which was viewed as a tremendous denunciation. (See 1 Cor. xvi. 22.) It signifies "the Lord will come;" *i. e.* to take vengeance.

MARANTA'CEÆ (Maranta, one of the genera), form the natural order of Endogenous plants, from which the most genuine kind of arrow-root is prepared. This substance is the starch contained in the tubers of *Maranta, Arundinacea,* and some other species, and of certain kinds of canna. *Marantaceæ* are very nearly the same as *Zingiberaceæ;* from which they differ in the flowers being more irregular, and the anther having but one lobe instead of two.

MARA'SMUS. (Gr. μαραινω, *I waste away.*) Emaciation; atrophy.

MA'RBLE. (Fr. marbre.) A term limited by mineralogists and geologists to the several varieties of carbonate of lime which have more or less of a granular and crystalline texture. In sculpture, the term is applied to several compact or granular kinds of stone susceptible of a very fine polish. The varieties of it are extremely numerous. The most valuable sorts used by the ancients were the *Pentelican,* which was white, and obtained from Mount Pentiles in Attica: the *Parian,* also called *Marpessian,* obtained from the island of Paros, was of a white colour, as was that from Mount Hymettus in Attica. Thasus and Lesbos also produced white marbles, which were in much repute. A place called Luna, in Etruria, produced a marble whose whiteness exceeded that from Paros. Of the white marbles were those from Mount Phelleus; from the neighbourhood of Coralios, in Phrygia; from Cyzicus, in Asia Minor; and the Marmor Phrygium, found near Synnada in Phrygia. The black marbles most used were from Tænarus, and the Numidian. The Chium Marmor, from the island of Chios, was of a black transparent chequered colour. The Obsidianum, procured from Ethiopia, was black. The Proconesian marble was with black veins. Mount Taygetes afforded the Marmor Laconicum, which was green, and is better known by the name of Verde Antique. A marble of mingled green was obtained from Carystus. The Atrician marble, from Mount Atrax in Thessaly, was a mixture of black, white, blue, and green. The Tiberian and Augustan marbles were green, and brought from Egypt. The Marmor Memphites was green, and is what we call serpentine. Corinth produced a yellow marble. The Marmor Phengites was white, with yellow spots; the Rhodian was marked with spots of a golden colour, and that of Milos yellow. In modern times the quarries of Carrara almost supply the world with white marble. Of variegated marbles there are many sorts found in this country of singular beauty. See ELGIN MARBLES: see also GEOLOGY.

MARCH. The first month of the Roman year, and the third of the English. In the ecclesiastical calendar used in England till the change of style in 1752 this was also the first month, as it was in the Roman. It is named Martius, in honour of Mars, the reputed father of Romulus. There is an old proverb still prevalent in Scotland, which represents March as borrowing three days from April, which have thence come to be designated the borrowed days. They will be found noticed in the *Complainte of Scotland.* Upon this subject Dr. Jamieson observes, "Those who are much addicted to superstition will neither borrow nor lend on any of these days. If any one would propose to borrow of them, they would consider it as an evidence that the person wished to employ the article for the purpose of witchcraft against the lenders."

MARCH. In Music, a military air, played by inflatile and pulsatile instruments, to regulate the steps and to animate the minds of soldiers. The march, however, has long been adapted to every species of musical instrument, and some of the most celebrated compositions of the greatest masters are in this style; as the March of the Priests in Mozart's *Zauber-flöte,* the Peasant's March in Weber's *Freischutz,* and above all Beethoven's Funeral Marches. In the Supplement to the First Edition of the *Encyclopædia,* it is truly said that a march should be always composed in common time, with an odd crotchet or quaver at the beginning. It is usually quick for ordinary marching, and slow for grand occasions; but no general rules can be laid down for its composition.

MARCH, in Military language, signifies the motion of a body of troops from one place to another. It consists of three measures: 1. ordinary time, in which about 75 paces are taken in a minute; 2. quick time, in which about 108 steps are taken in a minute; 3. the quickest, or as it is called *wheeling* time, at the rate of 300 feet in the same space.

MA'RCHES. The name given to the borders or frontiers of any district; but more especially applied to the boundaries between England and Wales, and England and Scotland. The term is derived from an old Anglo-Saxon word signifying a mark, and is to be found in every language of Teutonic descent. Several titles of dignity both in this and other countries derive their origin from their possessors having been appointed governors of the *marches* or frontiers of their respective countries; of these marquis in England and markgraf in Germany are the most prominent. The title Earl of March, now enjoyed by the Duke of Richmond, was originally bestowed on Mortimer, a member of the family so celebrated in English history, because he was the governor or superintendent of the Welch marches. In the middle ages, the name *marchers* was given to the noblemen who lived on the marches of Wales and Scotland. According to Camden they had once their own laws, and even the "power of life and death like petty kings;" but these privileges were abolished by Henry VIII. There was formerly a court of the marches of Wales in existence, where pleas of debt, or damages not above the value of 5*l.*, were tried and determined.

MA'RCIONITES. The followers of Marcion, a heretic of the 2d century, who adopted the Oriental notion of the two conflicting principles, and imagined that between them there existed a third power, neither wholly good nor evil, the Creator of the world and the God of the Jewish dispensation. The object of the Good Principle, or Supreme God, is to restrain the ambition of

these two powers, which wage a constant war against each other as well as himself. For this purpose it was that he sent his son Jesus Christ to destroy the Evil Principle on the one hand, and to counteract and coerce the power of the Jewish Deity on the other. The Marcionites were a branch of the great Gnostic heresy. Their opinions are found in the writings of Irenæus, Epiphanius, and Tertullian against them.

MARCO'SIANS. An early sect of Christians, a branch of the Gnostics, who derived their name from an Egyptian called Marcus, and reputed a magician. The Marcosians had a great number of apocryphal books which they held to be canonical; and many of their fables are still in use and credit among the Greek monks.

MA'REKANITE, is a variety of obsidian, found at Marekan in Siberia in small spherules.

MARGA'RIC ACID. (Gr. *μαργαριτη, a pearl.*) The substance into which the margarine, or concrete portion of certain oils, is converted by the action of alkalies. It has a pearly lustre, and is insoluble in water; but readily soluble in hot alcohol, which deposits it as the solution cools. It fuses at 140°, and reddens betimes. It closely resembles stearic acid.

MA'RGARINE. The solid fatty matter of certain vegetable oils has been thus termed by Lecanu, from its pearly lustre. The purest margarine is obtained from the concrete portion of olive oil.

MARGARI'TIC ACID. A distinctive term applied to one of the fatty acids which result from the saponification of castor oil. By the same process this oil also yields the ricinic and the elaiodic acids.

MARGARO'NE. When margaric acid is mixed with quicklime and distilled, a peculiar fatty product, which crystallizes in pearly scales, is obtained, which has been distinguished by the above term from other analogous substances.

MA'RGIN (Fr. marge), in Printing, is the arrangement of the pages in a sheet at proper distances from each other, according to the size of the paper; so that when the sheet is printed and folded, the border of white paper round them shall be regular and uniform in every leaf of the book.

MA'RGIN OF A COURSE. In Architecture, that part of the upper side of a course of slates which appears uncovered by the next superior course.

MARGI'TES. The title of a satirical poem attributed, but with little probability of truth, to Homer; if by him is meant the author of the *Iliad* or *Odyssey*. The subject of the poem, which has not come down to us, was the character of a silly empty-headed man (*μαργίτης*).

MA'RGRAVE, or more properly MARKGRAVE. A title of rank formerly used in Germany, and equivalent to the English marquis. Both words spring from a common origin. *See* Marquess.

MARI'A THERE'SA, ORDER OF. A military order of Austria, consisting of grand crosses, commanders, and knights: founded in 1757.

MARI'NES. A corps of men enlisted to serve as soldiers on board of ships of war in naval engagements, and on shore under certain circumstances. They sometimes assist, particularly in the British service, in performing some naval duties on board of ship. The period at which a distinct corps was embodied for this department of the British service is unknown. In 1684 mention is made of the Duke of York's maritime regiment of foot; and in the reign of Will. III. several regiments were placed on the establishment: these, however, were subsequently disbanded. In the beginning of Queen Anne's reign, six regiments of maritime soldiers were raised; and though these were again disbanded in 1749, six years afterwards, 130 companies were raised on the recommendation of Lord Anson, consisting in all of above 5000 men. Since the commencement of the present century great additions have been made to this corps; and at present its strength amounts to 9000 men. The men are clothed and armed in the same manner as the infantry of the line. The corps is commanded by a lieutenant-general and a major-general, who are naval officers, holding, in addition to their rank as such, these military titles: there are, also, four colonels commandants of divisions, besides four colonels and second commandants. No commissions in the corps are obtained by purchase; and the officers of marines rise in it by seniority, without, however, being able to obtain higher rank than that of colonels commandant. (See *Penny Cyclopædia.*)

MARIOTTE'S LAW. In Pneumatics, a general property of elastic fluids, first established by Mariotte; namely, that the elasticity or pressure is directly proportional to the density; or, which is the same thing, inversely proportional to the space which the fluid occupies. *See* Pneumatics.

MA'RITIME LAW, signifies the laws relating to harbours, ships, and sailors. It forms an important branch of the commercial law of all trading nations, and embraces an infinite variety of subjects, most of which have been defined under their respective heads. The most celebrated codes of maritime law have been, in classical times, that of Rhodes; in modern times, the *Consolato del Mare*, a compilation supposed to have been framed at Barcelona as early as the 9th century; the laws of the Isle of Oleron, in the time of Richard I. of England; the laws of Wisby in the island of Gothland, to which some northern jurists have assigned an earlier origin than the laws of Oleron, but which there can be little doubt were merely a compilation from those above specified. But by far the most complete and well-digested system of maritime jurisprudence that has ever appeared is that comprised in the *Ordonnance de la Marine*, issued by Louis XIV. in 1681, by which maritime law was elevated to the rank of a regular system, and has formed the basis of many of the subsequent decisions of English, American, and other foreign courts. This excellent code was compiled under the direction of M. Colbert, by individuals of great talent and learning, after a careful revision of all the ancient sea laws of France and other countries, and upon consultation with the different parliaments, the courts of admiralty, and the chambers of commerce of the different towns. It combines whatever experience and the wisdom of ages had shown to be best in the Roman laws, and in the institutions of the modern maritime states of Europe. In the preface to his treatise on the *Law of Shipping* Lord Tenterden says,—"If the reader should be offended at the frequent references to this ordinance, I must request him to recollect that those references are made to the maritime code of a great commercial nation, which has attributed much of its national prosperity to that code: a code composed in the reign of a politic prince; under the auspices of a wise and enlightened minister; by laborious and learned persons, who selected the most valuable principles of all the maritime laws then existing; and which, in matter, method, and style, is one of the most finished acts of legislation that ever was promulgated." The ordinance of 1681 was published in 1760, with a detailed and most elaborate commentary by M. Valin, in 2 vols. 4to. *See* Admiralty, Court of. (See also the *Commercial Dict.*)

MARK. An old coin current in England and Scotland, valued 13*s.* 4*d.* A piece of money so called is at present used in Hamburgh; it is equal to 1*s.* 4*d.* sterling.

MA'RKET. (Mod. Lat. mercheta, from merx.) In Law, the liberty or franchise whereby a town is enabled to set up and open shops, &c., at a certain place within its limits, for buying and selling, and better provision of such victuals as the subject wanteth. The establishment of a market, with the grant of the tolls thereunto belonging, is one of the king's prerogatives; and can only be effected by virtue of the king's grant, or supported on long and immemorial usage and prescription which presuppose such a grant. The general rule of law is, that all sales and contracts of any thing vendible in fairs or markets overt (*i.e.* open) shall not only be good between the parties, but valid against all claim by others having any right or property in the subject.

MA'RKING INK. An indelible ink used for marking linen; it effectively resists washing and almost all chemical agents: its basis is oxide of silver, which has a strong affinity for the fibre of linen and cotton, and acquires by exposure a black colour. A good marking ink is prepared by dissolving a drachm of fused nitrate of silver in half an ounce of distilled water, and colouring it with a little sap-green; but as this is apt to run if written with upon the unprepared linen, the place to be written upon is commonly prepared for its reception by the previous application of *liquid pounce*, which is made by dissolving two drachms of carbonate of soda and two drachms of gum arabic in four ounces of water: this also effectively precipitates the oxide of silver upon the vegetable fibre, and prevents any injury from the corrosive action of the salt of silver. A solution of ammonio-nitrate of silver, thickened by a little gum, forms a marking ink which may be used without any previous preparation.

MA'RKING NUT, in Botany, is the seed or nut of the *Semicarpus anacardium* a tropical tree, related to the cushew nut. It derives its name from the juice contained in its fruits staining linen of a deep and indelible black colour.

MARK, ORDER OF SAINT. A Venetian order of knighthood; St. Mark the Evangelist having been the patron of that republic. The knights were elected by the doge and senate.

MARL, is composed of carbonate of lime and clay in various proportions, and in different degrees of compactness and friability. In some marls the proportion of clay is small, in which case the marl, as a manure, acts on soils much in the same manner as lime; but where clay is the predominant ingredient of marl, it acts on the soil partly as lime, but principally by altering the texture of the soil. Hence all sandy soils are improved by marl, in consequence of its increasing their compactness and capacity for retaining moisture; while argillaceous marls applied to clays are of little or no use. From these long-established facts has arisen the old adage,—

Who marls sand shall bury land,
Who marls clay throws all away.

Marl is found in almost every country; not like limestone, in protruding rocks, but, from its friable nature, which moulders down into a comparatively earthy mass, under or near the surface of the soil, whence it is dug out and spread on the surface. Hence, while limestone is quarried, chalk and marl are dug out of pits. Marl has been in use in Europe since the time of the Romans: it is very generally employed as a manure in France and Germany, and in England it is most employed in Norfolk.

MA'RLINGSPIKE. An iron bolt tapering to a point for opening the strands of rope.

MA'RLY, MACHINE OF. A celebrated piece of mechanism, one of the most complex perhaps ever constructed, for raising water from the Seine to supply the town of Marly, as well as Versailles and Trianon. Its mean produce was from 30,000 to 40,000 gallons per hour; and was attended with an expense of about a farthing for 15 gallons. It was erected in 1682 by Runnequin, upon very unscientific principles, but still with considerable skill in its details. It was, as such complicated machines always are, often out of repair; and Hachette reports of it that, after 128 years, it fell into total ruin. Details of its construction may be seen in Belidor, *Arch. Hydraulique; Gregory's Mechanics*, vol. ii., and other places.

MARMORA'TUM. (Lat.) In Architecture, a cement formed of pounded marble and lime well beaten together.

MA'RMOT. The Rodent animal so called is the type of a genus (*Arctomys*) nearly allied to the squirrels, being characterized by having five molar teeth on each side of the upper and four on each side of the lower jaw, all bristled with points, and indicative of a somewhat mixed diet. The marmots, however, in their general form are nearly the reverse of the squirrels, being heavy, with short legs, a middle-sized or short tail, and a large flat head. They pass the winter in a state of torpor, concealed in deep holes, the entrance of which they close with a heap of dried grass. They are natives of Europe and North America, live in societies, and are easily tamed.

MA'RONITES. The followers of Maro, inhabitants of the mountains Libanus and Antilibanus in Syria, who adopted in the 7th century the opinions of the Monothelites; they continued to form a separate sect until the 12th century, when they became reconciled to the see of Rome. The Maronite writers, however, have always maintained their freedom from the errors imputed to them, and declare themselves to have been uniformly attached to the doctrines of the Catholic church. (*See* MONOTHELITES. (*Mosheim*, transl., ed. 1790, ii. 196.)

MAROO'NS. (Supposed to be derived from a word used in Spanish America, signifying *hog-hunters*.) A name given in Jamaica to runaway negroes. When Jamaica was conquered from the Spaniards a number of negroes, abandoned by their former masters, occupied some of the mountainous parts of the island, and caused great trouble to the colonists. About 1730 they became extremely formidable; but after a war of eight years at length submitted to a capitulation, by which they were allowed to retain their free settlements in the heart of the island; in 1795 a portion of them again rose in arms, but were speedily put down, and transported to a new settlement in Nova Scotia. (See *Dallas's History of the Maroons*.)

MARQUE, LETTER OF. A commission granted in time of war to a private person commanding a vessel to cruise at sea and make prize of the enemy's ships and merchandise: the ship so commissioned is sometimes called by the same name. (*See* REPRISALS, LETTER OF.) The word is derived from mark (Germ. *frontier*), as being a right of capturing property beyond the limits or frontiers of another prince.

MA'RQUESS. (Germ. mark, *a limit* or *frontier*.) A title of dignity in England, France, and Italy, next in rank to that of duke. It is of German origin; those military chieftains in the Teutonic kingdoms and empires which arose on the fall of the Western empire, who were entrusted with the defence of districts on the frontiers, having been styled mark-grafen, counts of the marches or frontiers (in Latin, marchiones). Many of these officers were appointed by Charlemagne, although he was not, probably, the first creator of the office. According to the ordinary cause of the development of feudal institutions, these chiefs, from military governors appointed for life, became territorial potentates, holding their lands by hereditary right; and, on the decay of that system, this honour, like others, became merely titular. In England, the first marquess was Robert de Vere, Earl of Oxford, created by Richard II., in 1387, Marquess of Dublin for life. The next creation was of John de Beaufort, Earl of Somerset, raised to the rank of marquess in 1397; which dignity he afterwards refused to bear, as a strange and novel one. (See Nicolas, *Introduction to the Peerage*, lxxvi.) After that period the title fell into disuse, until the reign of Edward VI.

MA'RQUETRY. (Fr. marquetrie.) In Architecture, inlaid work consisting of different pieces of divers coloured woods of small thickness glued on to a ground usually of oak or fir, well dried and seasoned, which, to prevent casting and warping, is composed of several thicknesses. The early Italian builders used it in cabinet work, and John of Vienna and others of his period by its means represented figures and landscapes; but in the present day it is chiefly confined in its use to floors, in which the various pieces of wood are usually disposed in regular geometrical figures, and are rarely of more than three or four species.

MA'RRIAGE, LAW OF. Marriage, in its legal sense, is a civil contract binding parties to certain reciprocal obligations; and the general principle of law respecting this, as well as other contracts, is, that it is to be held valid according to the usage of the country wherein it is made. Thus a marriage between English subjects in Scotland according to the formalities of Scottish law is binding, and the children of such parents are legitimate in England. A marriage between English subjects in France according to the ceremonies in the church of England would not be valid, according to the principles of general law, unless registered before the civil magistrate according to the provisions of the French code. But, by the statute 4 G. 4. c. 91. marriages between English subjects, solemnized abroad by ministers of the church of England in the chapel of a British ambassador or British factory, are valid in the United Kingdom.

Previous to the passing of the first Marriage Act in 1754, the law of England was governed by the canon law; and, consequently, an agreement to marry, followed by consummation, formed, as it now forms in Scotland, a sufficient union. That statute first rendered necessary the preliminaries of the publication of banns, or the obtaining a licence. It was amended by 4 G. 4. c. 17. But that act imposed so many additional restrictions on parties wishing to become husband and wife, that it was found necessary to repeal it in all haste, and another statute was passed (4 G. 4. c. 76.), by which English marriages were next regulated.

By this act the banns of marriage are to be published three Sundays in a parish church, or public chapel of the establishment, in the parish wherein both, or the parish wherein each, of the parties dwell. A licence is a dispensation by virtue of which marriage may be solemnized without the publication of banns. It is granted by *surrogates*, or persons having authority from the bishop. No licence can now be obtained, unless upon affidavit that the parish or district in which the marriage is to be solemnized has been the usual place of residence of one of the parties for fifteen days immediately preceding the granting of the licence. The affidavit must also declare that there is no impediment of kindred or alliance, nor any other lawful cause of hinderance.

A special licence dispenses with all restrictions as to time and place of marriage. By a regulation of Archbishop Secker it is not to be granted except to persons of a specified rank; but in practice the privilege is extended as a matter of favour. *See* REGISTRAR.

The power of parents and guardians, in restricting the marriage of minors under their tutelage, is now confined within the following limits. The publication of banns is void, if the parent or guardian of either party declare, or cause to be declared, their dissent in public at the time of the proclamation. In case of marriage of a minor by licence, the father or guardian, or if none the mother, or the guardian appointed by the court of chancery, must give consent, and such consent must be notified in the affidavit on application for the licence. If consent be unreasonably withheld, the only resource of lovers against the flinty hearts of parents or guardians is by petition to the lord chancellor, who may, if he pleases, interpose his judicial authority in favour of their union.

Marriage is void if solemnized knowingly and wilfully (by either party) in an unlawful place, or without banns or licence, or by any person not in holy orders. So if the banns be published, whether wilfully or accidentally, in a wrong name; unless it be a name by which the party is generally known. Marriages are also void where there is a prior existing marriage, and in case of lunacy or incapacity.

But if the marriage of a minor be duly solemnized, but by false oath or by fraud the necessary consent is dispensed with, such marriage is not void; but the party so offending shall forfeit, upon complaint of the parent or guardian, all property which might have accrued to such party by the marriage.

Proof of a marriage is by the evidence of a party who was present at the celebration; or by production of the parish register, and showing the identity of the parties.

The ecclesiastical courts have the direct cognizance of questions respecting the legality of a marriage; but as the common law courts decide in questions of property, and others in which the fact of marriage may be incidentally called in question, they can require proof of it without resorting to the assistance of the former.

Marriage is voidable by suit in the ecclesiastical court, where such marriage has been contracted under a ca-

nonical impediment; namely, consanguinity or affinity, or bodily incapacity of either of the parties. Marriages solemnized by force are also voidable, and such as are contracted in error under certain circumstances. A voidable marriage is good to all intents until rendered void by a sentence of the court.

Other matrimonial causes in these courts are—1. Jactitation of marriage. When one party gives out or reports that he or she is legally married to another, the person injured may *libel* the other (*see* ECCLESIASTICAL COURTS, under the head of LAW) in the spiritual court; and unless the defendant proves marriage, silence is enjoined, which is the only remedy the spiritual court can give.

1. Adultery, as a public crime, is left to the cognizance of the spiritual courts: as a civil injury, it is pursued by the husband in an action of trespass for damages against the adulterer in those of common law.

2. In suits on the ground of adultery in the spiritual court the remedy prayed is a separation, or divorce *à mensâ et thoro*, from bed and board. And it may be obtained by either party; but will be refused in case the other party recriminates and mutual unfaithfulness is proved, or in case other circumstances are shown which, in the opinion of the court, disentitle the complainant to the remedy he prays for.

A divorce *à vinculo matrimonii*, that is, the annulment of marriage, can only be conferred by act of parliament. Evidence must be given on applying for the bill that there was judgment for the plaintiff on an action for damages against the seducer; or sufficient cause shown why such action was not brought or such judgment obtained.

3. Another ground on which the spiritual courts will grant a separation is cruelty; but the cruelty for which such relief can be granted is only such as directly endangers the life or health of the injured party.

4. A suit for restitution of conjugal rights is to compel mutual cohabitation. And no deed of separation or mutual agreement, nothing short of a sentence by the court, can bar the complainant of his or her right to promote this suit; but cruelty or adultery may be pleaded in reply, as constituting lawful grounds for separation.

5. Alimony is that legal proportion of the husband's estate which, by the decree of the ecclesiastical court, is allotted to the wife for her maintenance during the pendency of a suit between them; or after a sentence of divorce *à mensâ et thoro* by reason of the cruelty or adultery of the husband, the permanent allowance to be paid to the wife during their separation. The quantum of alimony is decided by the court on a statement of the husband's property (called *an allegation of faculties*) and his answer thereto.

Marriage, its Effect on Property.—The consideration of the legal effect produced by marriage on the property of the parties contracting it divides itself into,—

1. The law of husband and wife, as it respects property acquired by either before marriage.

2. As it respects property acquired by either after marriage.

3. As its dispositions are affected by separation or divorce.

(1, 2.) As to real property. If the wife is seised of lands or tenements in an estate of inheritance, and dies having had issue born living, the husband is entitled to the lands or tenements for his life, being tenant, as it is termed, by the courtesy of England; and this, whether the lands be held by a legal or equitable title.

Dower is now, since the statute 3 & 4 W. 4. c. 115., the wife's right to one third part, for life, of all estates of inheritance which her husband dies entitled to or seised of in possession. It formerly attached to all estates of inheritance of which he was at any time possessed, so that he could not defeat her title by alienation, but to legal estates only. Since the 1st January, 1834, the period on which the above-mentioned act came into operation, equitable estates are also subject to it. It has long been customary to bar this right to dower by various complicated processes, which the law has permitted to defeat the wife's claim; and especially by settlements before marriage, giving a jointure or provision in lieu of dower. It may now be barred by the husband's alienation in his lifetime; or by his will; or by a declaration in the deed of conveyance of the land to the husband. Anciently a *feme covert* could only alienate real property by the public solemnity of a *fine*; now, by a deed executed after her examination by commissioners, to show that no control is exercised by the husband.

All the *personal* property to which a woman is entitled vests in her husband by marriage. Her *chattels real*, that is, leasehold property for a term of years, will revert to her if she survive him; and although the husband may alienate them in his lifetime, he cannot dispose of them by will. But should he survive her, they are his absolutely. Her *chattels personal*—money and goods—are his without restriction, to give or bequeath as he pleases even in her lifetime. Her *choses in action* (that is, property of which there is no immediate occupation, as debts due to her, money in the funds, &c.) are the husband's property *conditionally*; that is, if he reduce them into possession by exercising his rights over them during her life. If not, they survive to her absolutely; and should she die first, he only takes them as her administrator, which he is by right.

If the husband die intestate, the wife is entitled to half his personal property if there be no issue, and to one third if there be issue.

The husband is liable for all his wife's debts and engagements made while unmarried; but not for such as she may have contracted during a former marriage. But he is released from his liability by her decease; and if he die first, she only is responsible. For debts contracted by the wife during marriage the husband is not liable unless they have been contracted with his consent, express or implied; and this implied assent gives rise, as may well be supposed, to numberless questions in courts of law.

As to the acts of husband and wife before marriage:—The will of a bachelor or widower not having children is revoked by his subsequent marriage and birth of issue. A warrant of attorney given by an unmarried woman is revoked by her marriage. So is her will, in every case; but there are others of her acts—such as the grant of a lease at will—which are not revoked, but merely revocable.

Settlements or articles, made in contemplation of marriage, are contrivances to modify the effects which would be produced by the mere act of law on the rights of the respective parties; and also to ensure an alienable provision for issue. It is usual to vest the property of both parties in trustees; generally for the benefit of the husband during their joint lives, then for the benefit of the survivor, after his or her death for the benefit of the children, in such proportions as the nature of the property or circumstances of the family may dictate. But it is usual to give authority to the parents by means of a *power* to vary these relative proportions. A jointure, although, in the strict sense of the word, a joint estate to husband and wife, is in practice a separate estate to the wife in lands and tenements, to take effect immediately on the husband's death, and to secure a competent provision for her during her life at least: it is usually provided by settlement, and bars dower. Pin-money is an annual income settled gratuitously before marriage by the husband on the intended wife; usually by means of trustees.

But in other cases, and especially when the casualties of a trade render it desirable to secure a certain protection, the wife is provided for in the settlements by vesting her own property, or a portion of it, in trustees for her sole and separate use. In this case the sums so secured are wholly independent of her husband's control. Where bequests are made to a married woman for her separate use, and no trustees are named to protect them, a court of equity will consider her husband a trustee for her. She may sue him, or any other person, in those courts, in respect of such property. Her savings out of it are likewise hers in separate right. But savings made by a wife out of an allowance for her private expenditure are not in every case her separate property.

A married woman has also a claim, in a court of equity, to a provision out of her own property in several cases, especially where the husband deserts or ill-treats her, or where, being a ward of chancery, she is clandestinely married.

(3.) On a divorce *à vinculo matrimonii* dower is gone: and if such divorce be on account of pre-contract, consanguinity, or affinity, the children are illegitimate, and the wife's property is restored to her. But a divorce *à mensâ et thoro* does not bastardize the children or bar dower.

Adultery during a voluntary separation entitles the aggrieved party to a divorce *à mensâ et thoro* as much as during cohabitation; and frees the husband from all debts of his wife, or claims by reason of her.

A husband is not held liable for debts contracted by his wife, even for necessaries, if he have turned her out of doors for adultery; or if, after being turned out, she commit adultery; or if she depart from him without his consent; or if she elope with an adulterer; or if the husband and wife separate by mutual agreement, in cases where the wife has separate means, or is provided for by separate maintenance.

Bigamy, or polygamy, is a felonious offence, punishable by transportation for seven years; and is now (since the statute 9 G. 4. c. 31.) equally punishable, although the second marriage took place out of the jurisdiction of English law.

A wife committing any felony, except murder or manslaughter, in company with her husband, is not responsible for the offence; but she is indictable for high treason so committed.

In both civil and criminal cases (with the exception of treason), husband and wife are not allowed, except under particular circumstances, to give evidence for or against each other.

MARS. In the Solar System, one of the old planets, and the fourth in the order of distance from the sun. The mean distance of Mars from the sun is 1·5236923, the mean distance of the earth from the sun being 1: it is, consequently, about 142,000,000 of miles. Mars performs his mean sidereal revolution in 686·9796458 mean solar days, and his synodical revolution (that is, returns to the same position in respect of the earth and sun) in 779·936 days. His orbit, at the beginning of the present century was inclined to the ecliptic in an angle of $1^\circ 51' 6''$; and its eccentricity is ·093307, half the major axis being unit. His apparent diameter varies from $3{\cdot}6''$ at his greatest, to $18{\cdot}28''$ at his least distance from the earth. At his mean distance the apparent diameter is $6{\cdot}29''$; whence the true diameter is found equal to ·517, that of the earth being unit, or about 4100 miles. Mars has a rotation about his axis which is performed in 24 h. 39 m. 21 sec. The inclination of the axis to the ecliptic is $30^\circ 18'$. When the opposition of Mars takes place at the time he is near the aphelion of his orbit he is then at his least distance from the earth, and presents an interesting appearance when seen through a powerful telescope. "In this planet," says Sir John Herschel, "we discern, with perfect distinctness, the outlines of what may be continents and seas. Of these the former are distinguished by that ruddy colour which characterizes the light of this planet (which always appears red and fiery), and indicates, no doubt, an ochrey tinge in the general soil, like what the red sandstone districts on the earth may possibly offer to the inhabitants of Mars, only more decided. Contrasted with this (by a general law in optics) the seas, as we may call them, appear greenish. These spots, however, are not always to be seen equally distinct, though, when seen, they offer always the same appearance. This may arise from the planet not being entirely destitute of atmosphere and clouds; and what adds greatly to the probability of this is the appearance of brilliant white spots at its poles, which have been conjectured, with a great deal of probability, to be snow; as they disappear when they have been long exposed to the sun, and are greatest when just emerging from the long night of their polar winter." (*Astronomy*, *Cab. Cyc.*) See PLANET.

MARS, or MAVORS. The Latin names of the deity called by the Greeks Ἄρης. He was fabled to be the son of Juno, conceived by means of the virtue of a certain plant; and was worshipped as the God of War. At Rome he was honoured as the progenitor of Romulus, the founder of the city, of which he was held to be the protector; and it was to the honour of this divinity that the Latin husbandmen used to offer up a peculiar sacrifice, called *suovetaurilia*, which, as the derivation of the word implies, consisted of a pig, a sheep, and a bull. The priests of Mars were called *salii*, and to their care was intrusted the sacred shield (*ancile*), which was said to have fallen from heaven during the reign of Numa. See SALII, ANCILE.

MARSEILLAISE HYMN. The name popularly, though erroneously, given to the national anthem of the French. The origin of this song, which has played so important a part in the revolutions not only of France but of other continental states, was long involved in obscurity; and we scarcely think it will be considered out of place to embody in our pages the following statement respecting it, which may be relied on as authentic: — The *Marseillaise Hymn* was the production of Rouget de Lille, a French officer of engineers, who was quartered at Strasburg in the year 1791, when Marshal Luckner commanded the army, at that time entirely composed of young conscripts. The marshal was to march the following morning of a certain day; and, late in the evening previous, he inquired if there were any men of a musical or poetical genius in the army who could compose a *soul-inspiring* song to animate his young soldiers. Some one mentioned Captain Rouget de Lille, who was immediately ordered into the presence of the marshal to receive his commands on the subject; which having been given, and a promise made by De Lille that a song would be ready the following morning, he went to his quarters, and during the night he not only wrote the song in question, but also set it to music; and next morning the army marched to its tune, and carried every thing before it with an enthusiasm only to be equalled by absolute frenzy.

The song is said to have been styled the *Marseillaise Hymn* from a body of troops, on their march from Marseilles, having entered Paris playing that tune at a time when it was little known in the capital. The *original* of the *Marseillaise* is said to be in the possession of Louis Philippe.

MARSH. A flat surface, the soil of which is so far saturated with water throughout the year as to be unfit for culture by the spade or plough; but not so much as to prevent it from producing coarse grasses, and other kinds of herbage. Marshes are generally situated in bottoms, where they are kept moist by the water which descends from the surrounding lands; or along the banks of rivers or lakes, where their humidity arises from their being nearly on the same level with the adjoining water. Where a marsh is situated so as to be occasionally overflowed by the sea, or by a river up which the tide flows, it is called a salt marsh; and the herbage produced by such lands is found highly conducive to the health of animals which pasture on them for a certain portion of the year, from the alterative effect of its saline properties.

MA'RSHAL. A title of honour in many European countries, applied to various dignities and high offices. The derivation of the word, and its early use, are extremely uncertain. The title of Marshal of England is now hereditary in the family of the Dukes of Norfolk. William Fitz-Osborn and Roger de Montgomery are said to have been marshals to William the Conqueror: their successors for some time are not accurately known; but the office was held in 1138, in fee, by the family of Clare, and thence descended to the Earls of Pembroke, and thence to Roger de Bigod, Earl of Norfolk, who surrendered it to Edward I. After being granted for life, and during pleasure, to several successive marshals, the dignity, with the title of Earl Marshal, was given to Mowbray, afterwards Duke of Norfolk; in whose family the dignity subsisted until it reverted to the crown in the reign of Edward IV. Richard III. granted it to his favourite, Howard, Duke of Norfolk; after whose death and attainder it passed through many hands; but was by Charles I. granted for life to his descendant, Thomas Howard, Earl of Arundel; and finally his grandson, Henry Howard, Earl of Norwich, was constituted hereditary earl marshal of England in 1672, with remainder to the issue male of the Earl of Arundel aforesaid; in which latter line it now subsists. The earl marshal is eighth in rank among the great officers of state in England. He has the same jurisdiction over the court of chivalry which was formerly exercised by the constable and marshal jointly.

Marshal of the King's Household, or Knight Marshal.— An officer whose office is said to be to hear and determine pleas of the crown, and suits between those of the king's household and other persons within the verge. The marshal of the King's Bench has the custody of the King's Bench prison in Southwark.

Marshal of France is the highest military rank in the French army. This officer appears first in history under the reign of Philip Augustus, as commander-in-chief of the royal armies. The number of marshals was increased by several successive sovereigns: in the reign of Henry IV. the states of Blois limited it to four, but this restriction was not observed; and, in the reign of Louis XIV., there were at one period no less than twenty. In the same reign officers of the navy as well as the army received the rank of marshal. The marshals bore two batons or marshal's staffs — azure, semés of fleur de-lys or, saltier-wise — as the token of their dignity. After the deposition of Louis XVI. the dignity of marshal ceased; but was revived by Napoleon, with the title of Marshal of the Empire.

MA'RSHALLING. In Heraldry, the arrangement and distribution of coats in a shield so as to denote the several matches and alliances of the family. See BLAZONRY.

MA'RSHALSEA. In Law, the court or seat of a marshal. The King's Bench prison, in Southwark, is said to be so called because the marshal of the king's house was wont to sit there, or to keep his prison. The Marshalsea, or Knight-marshal's Court, commonly called the Palace Court, was created by Charles I.; and has jurisdiction of personal actions within a circuit of twelve miles round Whitehall.

MARSH MIASMA. The infectious vapours which rise from certain marshes and marshy soils, and which tend to the production of intermittent and remittent fevers.

MARSU'PIALS, *Marsupialia*, or *Marsupiata*. (Lat. marsupium, *a pouch*.) An order of Implacental Mammiferous quadrupeds, of which the females have a portion of the abdominal integument folded inwards, forming either a depression containing the mammæ, or a pouch serving also as a temporary abode for the young; and the males have a corresponding portion of the abdominal integument extended outwards, forming a scrotum or pedunculate bag for the testes. In both sexes two supplementary trochlear bones are developed in the internal pillars of the abdominal rings, and are articulated to the anterior part of the brim of the pelvis, around which bones plays the muscle supporting and compressing the testes in the male, and the mammary glands in the female: the trochlear ossicles, from their connection by means of these muscles with the pouch, are called "marsupial."

The quadrupeds associated together by the common external and osteological characters above defined so far resemble the oviparous animals that a placenta is not organized, and the chorion of the fœtus contracts no adhesion with the parietes of the uterus. The fœtus is prematurely born after a gestation of only thirty-eight

days, in the great kangaroo, in which it does not exceed an inch in length. It is then received into the pouch, and adheres to the nipple for many months before it quits the pouch. The generative organs themselves, both male and female, offer several striking peculiarities common to all the Marsupials, and by which they differ from the ordinary Mammalia. Cuvier accordingly, in 1816, separated the marsupial from the other unguiculate quadrupeds, to form a distinct group, which he describes as forming with the Monotremes a small collateral chain; all the genera of which, while they are connected together by the peculiarities of the generative system, at the same time correspond in their dentition and diet, some to the Carnivora, others to the Rodentia, and a third tribe to the Edentata. M. de Blainville, in the Tables of the Animal Kingdom which he published in the same year, 1816, constituted a distinct subclass of Cuvier's "small collateral chain" of mammals, and gave to the subclass the name of *Didelphes*, in antithesis to that of *Monodelphes*, by which he distinguished the Placental Mammalia.

Many acute and sound-thinking naturalists refused their assent to these views, which, as they were supported by a knowledge of the conformity of organization of only the generative system in the Marsupials, were unquestionably defective in the evidence essential to enforce conviction. The best arguments for returning to the older views of classification, and for distributing the marsupial genera, according to the affinities indicated by their dental and locomotive systems, among the different orders of the Placental Mammalia, were advanced by Mr. Bennett, the accomplished author of *The Gardens and Menagerie of the Zoological Society delineated* (vol. i. p. 265.); and these have been repeated with approbation, and adopted by later classificators, as Mr. Swainson.

The discovery of the true affinities of the Marsupialia could only flow from an insight into their whole organization; and the question which Mr. Bennett proposes, with reference to the genus *Phascolomys*, "What is there of importance in the structure of the wombat, except this solitary character of the marsupium, to separate it from the Rodent order?" — a question which he might, in 1831, have asked with equal force in reference to any other marsupial genus — could only be answered satisfactorily by the anatomist who had submitted the Marsupialia in question to a thorough dissection.

Although the Marsupials present modifications of the dental system corresponding with the carnivorous, omnivorous, and herbivorous types, yet they agree with each other, and differ from the analogous Placental Mammalia in having four instead of three true molars, *i. e.* four molars which are not displaced and succeeded by others, in the vertical direction.

In the locomotive organs it is true that we see some of the Marsupials having a hinder thumb, like the Placental Quadrumana; others are digitigrade, with falculate claws, like the Placental Feræ; a third, as the wombat, has the feet adapted for burrowing; a fourth, like the Cheironectes, is aquatic, and has webbed feet; yet all these Marsupials agree with each other in having a rotatory movement of the hind foot, analogous to the pronation and supination, which, in the placental quadrupeds, are limited, when enjoyed at all, to the fore feet; and they manifest, moreover, a peculiar modification of the muscles of the hind leg and foot, in relation to these rotatory movements. In those Marsupials, as the kangaroos, potoroos, and perameles, in which the offices of support and locomotion are devolved exclusively or in great part upon the hind legs, these are strengthened at the expense of the loss of the rotatory movements of the feet; but in the enormous development of the two outer toes, and the conversion of the two inner ones into unguiculate appendages, useful only in cleansing the fur, these Marsupials differ from all Placentals, whilst the same peculiar condition of the toes may be traced through the Pedimanous group of Marsupials. Thus the locomotive organs, notwithstanding their adaptation to different kinds of progression, testify to the unity of the marsupial group in the two remarkable peculiarities of structure above cited.

The vascular system gives evidence to the same effect. All the Marsupials present the following peculiarities in the structure of the heart; viz. the right auricle manifests no trace of either *fossa ovalis* or *annulus ovalis*, and receives the two *venæ cavæ superiores* by two separate inlets. This generalization is, however, less urgent in the present question than the preceding, because the modification, as regards the separate entry of the superior *venæ cavæ* obtains in a few placental species, as the elephant and certain Rodents; but as the first-cited cardiac character is common and peculiar to the Marsupial Mammalia, and as the second, while it is universal in the Marsupials, occurs only as an exceptional condition in the placental series, the arguments which they afford to the unity of the marsupial group cannot be overlooked in a philosophical consideration of the affinities of the Mammalia.

With respect to the nervous system, it has been shown that, in the structure of the brain, the Marsupialia exhibit a close correspondence with the Ovipara in the rudimental state of the *corpus callosum:* the difference which the most closely analogous placental species offer in this respect is broadly marked. (*Owen on the Brain of the Marsupial Animals, Phil. Trans.* 1837, p. 89. pl. vi.)

These coincidences in the Marsupialia of important organic modifications of the dental, locomotive, vascular, cerebral, and reproductive systems, establish the fact that they constitute a natural group, inferior, on the whole, in organization to the Placental Mammalia.

The following is a tabular view of the subordinate divisions of the Marsupialia regarded as an order of the Implacental subclass of Mammalia: —

Classification of the Marsupialia.

Tribes.	Families.	Genera.	Subgenera.
SARCOPHAGA.			
Three kinds of teeth; canines long in both jaws; a simple stomach; no *intestinum cæcum*.	*Dasyuridæ* -	Thylacinus. Dasyurus. Phascogale.	
Extinct transitional forms - - - -	- -	Phascolotherium Thylacotherium	Fossil.
ENTOMOPHAGA.			
Three kinds of teeth in both jaws; a simple stomach; a moderately long *intestinum cæcum*.	*Ambulatoria* -	Myrmecobius.	
	Saltatoria -	Chæropus. Perameles.	
	Scansoria -	Didelphys - -	Didelphys. Cheironectes.
SARCOPHAGA.			
Anterior incisors large and long in both jaws; canines inconstant; stomach simple, or with a special gland; a very long *intestinum cæcum*.	*Phalangistidæ* -	Phalangista - -	Cuscus. Pseudocheirus. Tapoa.
		Petaurus - -	Petaurista. Belidia. Acrobata.
	Phascolarctidæ -	Phascolarctus.	
POEPHAGA.			
Anterior incisors large and long in both jaws; canines present in the upper jaw only, or wanting; a complex stomach; a long *intestinum cæcum*.	*Macropodidæ* -	Hypsiprymnus. Macropus.	
RHIZOPHAGA.			
Two scalpriform incisors in both jaws; no canines; stomach with a special gland; *cæcum* short, wide, with a vermiform appendage.	*Phascolomyidæ*	Phascolomys.	
		Diprotodon -	Fossil.

MART. *See* FAIR and MARKET.

MARTE'LLO TOWERS. The name given to the circular buildings of masonry which were erected along different parts of the British coasts at the commencement of the present century, intended as a defence against the meditated invasion of Napoleon. The origin of the name is usually supposed to be derived from a fort in Mortella (Myrtle) Bay, Corsica, which, after a determined resistance, was at last captured by the British in 1794. These towers were provided with vaulted roofs, and consisted of two stories, — the lower for the reception of stores, the upper, which was shell-proof, for the casement of troops; and the wall of the building terminated in a parapet, which secured the men in working the pieces of artillery,

which besides were constructed on moving pivots, so as to be fired in any direction. In most places of England these towers have been dismantled; those that remain either serve as stations for the use of the coast blockade force, or, like that near Leith, are not employed for any purpose.

MARTINE'T. A cant phrase for a severe military disciplinarian; probably derived from a certain Colonel Martinet, who served in the French army under Louis XIV., who was the inventor of a peculiar whip, called by his name, for the purpose of military punishment, and also (if Voltaire may be believed) of the bayonet.

MA'RTINGALE. In Naval affairs, a rope leading downwards from the jib-boom end, to keep the jib-boom down against the force of the sail and stay. In the manége, martingale is applied to a thong of leather fastened at the end of the girths under the belly of a horse, and at the other end to the musrol, passing between the legs to keep him from rearing.

MA'RTLET. In Heraldry, a fanciful bird, shaped like a martin or swallow, but depicted with short tufts of feathers in the place of legs. It is the difference or distinction of a fourth son.

MA'RTYR. (Gr. *μαρτυρ*, or *μαρτος*, *witness:* in which sense the word is used by the writers of the N. Test. when speaking of themselves, in reference to the testimony they bore to the actions of Christ.) When the members of the Christian church were subjected to persecution under the Roman emperors, the persons accused were questioned as to their belief; and, in undergoing punishments and death, were said to bear witness of their master before the world. A distinction was also made between those who, although they boldly asserted their belief, were yet not visited with extreme punishment, who were designated under the name of *confessors*, and those who actually suffered death, who alone were dignified with the title of martyrs, and said to obtain the crown of martyrdom. Martyr, in its ordinary signification, denotes a person who suffers death or persecution on account of his belief. (See *Mosheim's Eccl. History* (transl.), ed. 1790, i. 77.; *Gieseler* (transl.), c. 8. 14. 71. &c. As to the intercession of martyrs, *Ib.* 109. 162.)

MA'RTYRO'LOGY. (Gr. *μαρτυς*, and *λογος*, *a description.*) The name given to that department of ecclesiastical history which relates to the acts and deaths of martyrs. It also signifies a calendar or register kept in religious houses, wherein were inserted the names and donations of their benefactors, and the days of their death. As specimens of this species of works, we may mention the *Martyrology* of Eusebius, which was so celebrated in the early church, but which is lost; and *Fox's Book of Martyrs*, the most valuable record of the sufferings of the English reformers. Many of the accounts in the early martyrologies are purely fabulous. See *Ruinart's Acta Martyrum;* Baronii, *Martyrologium Romanum;* and *Middleton's Free Inquiry.* Gallonius, *De Sanctorum Martyrum Cruciatibus*, 1598, and subsequent editions, is a book which has had great popularity on the Continent.

MASCA'GNIN. A mineralogical name of the native sulphate of ammonia of volcanic districts; named after Mascagni, who first discovered it.

MA'SCLE. In Heraldry, a bearing in the form of a lozenge perforated; supposed to represent the meshes of a net.

MA'SONRY. (Fr.) The science of combining and joining stones for the formation of walls and other parts in constructing buildings. The science, when applied in the construction of domes, groins, and circular arches, is difficult and complicated, depending on a thorough knowledge of descriptive geometry. Hence the various methods of obtaining the requisite lines for the artificer would require a space and diagrams which cannot be given here; but the reader who desires acquaintance with that part of the subject may consult Rondelet, *Traité Théorique et Pratique de l'Art de Bâtir*, Paris, 1829-30, 4to., with the certainty of finding all the information he requires. Vitruvius mentions several kinds of masonry among the ancients, which were distinguished from each other by the different modes of arranging the stones. The principal are, 1. The *Reticulatum*, which is arranged in diagonal courses, like the meshes of a net; whence its name. 2. The *Incertum*, wherein the rising courses are so laid, without any *certain* sizes of the stones, as that the vertical joint above always falls over the middle of the joint below. The appearance of this work is not perhaps so pleasing as that of the first, but the work itself is stronger. 3. The *Isodomum*, in which all the courses are of equal height, as its name imports. 4. The *Pseudisodomum*, which received its name from the courses being unequal in height. 5. The *Emplectum*, in which the faces of the work were wrought, and the centre of the wall filled up with rubble work, in which species of work the Greeks employed *diatoni* or bond stones, running in one piece through the thickness of the wall to tie it together. The first principles to be attended to in building stone walls are, that the vertical joints in any course should not fall over the vertical joints in the course immediately below it; and that where the thickness of the wall consists of two or more pieces of stone, bond stones or blocks which run through the whole wall transversely, if possible in one piece, should be introduced as frequently as possible for the purpose of binding the whole mass together. The different species of masonry in present use may be reduced to four:— 1. *Bond masonry*, wherein the stones of each succeeding course are laid so that the joint that mounts and separates two stones always falls directly over the middle of the stone below. 2. That of *brickwork*, where the bodies and projections of the stones enclose square spaces or panels, &c. formed with bricks. 3. That called by the French *de moilon*, or small work, wherein the courses are equal, well squared, and their edges or beds rusticated. 4. That wherein the courses are unequal, and filled up in the middle with small stones and mortar.

MASONRY. *See* FREEMASONRY.

MASQUE, or MASK. A species of drama. It originated from the custom in processions, and other solemn occasions, of introducing personages in masks to represent imaginary characters. Many of these characters, even in the religious shows of Italy, &c., were of a grotesque description, and the performance often intermixed with dancing and buffoonery. By degrees, in England, something of a dramatic character was added to these exhibitions. At first, as in the well-known progresses of Queen Elizabeth, monologues or dialogues in verse were put into the mouths of the masked performers; and, in the reign of James I., they had ripened into regular dramatic performances: sometimes, as in the *Tempest* of Shakspeare, introduced by way of interlude in regular plays; at other times acted as separate pieces, with much machinery and decoration. Ben Jonson was the first, and indeed almost the only classical English writer (with the exception of Milton, in the solitary and noble specimen of *Comus*) who devoted much labour and taste to this department of the drama. His masques were represented at court: the queen of James I., and after her the accomplished Queen Henrietta Maria, did not disdain to take part, at least as silent dramatis personæ, in some of these pageants. The taste for them died away in the reign of Charles I.; and after the interruption given to the progress of dramatic art and literature by the civil wars, they were not again brought into fashion.

MASQUERA'DE. (Ital. mascherata.) An amusement practised in almost every civilized country of modern times, consisting of a ball and other festivities, in which only those who are masked or disguised can participate. This species of amusement had its origin in Italy, where, according to *Hall's Chronicle*, they had become fashionable so early as the beginning of the 16th century. Of its introduction into England Hall thus speaks:—"On the date of the Epiphaine, at night (A. D. 1512-13), the king (Henry VIII.) with eleven others were disguised after the manner of Italie, called a maske, a thing not seen afore in England; they were apareled in garmentes long and brode, wrought all with golde, with visers and cappes of golde; and after the banket doen, these maskers came in with the six gentlemen disguised in silk" (in all probability the *domino* of more recent times), "barynge staffe torches, and desired the ladies to daunce: some were content; and some that knew the fashion of it refused, because it was not a thing commonly seen. And after thei daunced and commoned together, as the fashion of the maskes is, thei toke their leave and departed, and so did the quene and all the ladies." The invention of masquerades is ascribed to Granacci, who died in 1543.

MASS. (Lat. missa.) The name by which the Roman Catholics designate the celebration of the Lord's Supper after the forms of their church. The term is derived from the phrase, "Ite, missa est, concio" (i. e. *Go, the assembly is dissolved*); by which the priest, in the primitive ages, signified to the catechumens that all that part of the service of the church was concluded which it was allowed to all believers indiscriminately to attend. The communion of the eucharist was extended only to the higher class, the *fideles*, who had completed the period of initiation and instruction: and, after the pronunciation of these words, the offering of the body and blood was made. It was to this offering itself that the term missa came to be applied. The service of the mass, as it is still retained throughout Catholic countries, was the work of Gregory I. in the 6th century. It consists of three parts: the offertorium, or offering of the elements upon the altar; the consecration, by which they are supposed to undergo the transubstantiation into the real body and blood of Christ; and the sumption, or actual participation in them by the communicants. These ceremonies are accompanied by the recitation of various prayers; and the priests go through numerous evolutions, which are supposed to represent the circumstances attending the passion of our Lord. High mass is the performance of this service accompanied with music.

MASS. (Germ. masse.) The quantity of matter of which any body is composed. The mass is directly as

the product of the volume of the body into its density. The mass multiplied into the constant force of gravity constitutes the weight; and hence the mass of any body is rightly estimated by its weight. *See* MECHANICS.

MASS. In the Fine Arts, a large quantity of matter of light or shade. It is generally applied in painting to light and shade brought upon objects proper for their reception, and grouped or arranged so as to give repose and pleasing variety both of one and the other without being scattered.

MASSA'LIANS. *See* EUCHITES.

MA'SSETER. (Gr. μασσαομαι, *I chew.*) A short thick muscle which raises the lower jaw, and assists in moving it backwards and forwards in the act of chewing.

MA'SSICOT. Yellow oxide of *lead*.

MA'SSORA, or MASORA. A critical work among the Jews, containing remarks on the verses, words, letters, and vowel-points of the Hebrew text of the Bible. As the sacred books were originally written without any breaks or divisions into chapters or verses or even words, the Jews found it necessary to establish a canon to fix and ascertain the reading of the Hebrew text. This rule or canon is designated *Massora*, or tradition, in which the verses, letters, words, &c., are all numbered; and by this means the slightest variations can be detected. The Jewish rabbis who drew up this work are styled Massorites. *See* BIBLICAL HISTORY, &c.

MAST. A long piece or system of pieces of timber, placed nearly perpendicularly to the keel of a vessel to support the yards or gaffs on which the sails are extended. When a mast is one entire piece, it is called a *pole-mast;* but in all large vessels it is composed of several lengths, called *lower*, *top*, and *top-gallant* masts: sometimes a fourth, called a *royal* mast.

The method of supporting each mast on the one next below it is peculiar. On the sides of the lower mast, some feet below the head, are placed cheeks: on these are fixed horizontally two short pieces of wood, fore and aft, called *trestle trees*. Across these at right angles are laid, before and abaft the mast, two or more longer and lighter pieces, called *cross trees*, which give the name to the entire system. On the mast head itself is a *cap*.

The topmast being placed up and down, the fore side of the lower mast is *swayed up* between the trestle trees, and through the round or foremost hole in the cap. When raised so high that the *heel* of the topmast is nearly up to the surface of the cross trees, a piece of iron, called the *fid*, is put through the hole in the heel for the purpose; and on this fid, of which the ends are supported on the trestle trees, the topmast rests. When fidded, the topmast is *stayed*, and the rigging or shrouds *set up* to the *dead eyes* in the ends of the cross trees. These dead eyes pull from the lower rigging below, and thus the cross trees serve merely to extend the rigging. The topgallant is supported in the same manner on the topmast. When the mast is to be taken down, it is first raised to relieve the fid; which being drawn out, the mast is lowered.

The masts are supported by a strong rope, leading forward, called the *stay;* by others, leading aft on each side of the ship, called, in general, *backstays;* and by others abreast, called *shrowds*, and also *breast backstays*.

Large lower masts are composed of pieces, and have for some years been made of several lengths, about a foot or so square, and the whole supported merely by hoops at intervals.

The *main-mast* is near the middle of the vessel, the *fore-mast* is that which is nearest the fore part, and the *mizen-mast* is abaft the mainmast.

The old rule for the length of the main lower mast is to take $\frac{1}{2}$ the sum of the length of the lower deck and extreme breadth: the fore-mast is $\frac{8}{9}$ths of the main-mast, the mizen-mast considerably smaller. The top-mast is about $\frac{3}{5}$ths of the lower-mast. These rules, as well as others for the thicknesses, &c., are merely for convenience, based on no mechanical principle, and are by no means strictly followed.

MA'STER. (Lat. magister.) A title frequent among the Romans: as magister equitum (master of the horse, the lieutenant or second in command to a dictator), magister peditum, magister census, &c. Magister militiæ (master of the army, or of military affairs) was a title under the later Roman emperors. *Grand master*, in modern times, is the common title of the chief of the orders of knighthood, and of some fraternities, as the Freemasons. The eldest sons of some noble landed proprietors are designated as masters in Scotland; as the master of Gray, master of Douglas, &c.

MASTER. In the Universities, a degree in arts; the most ancient of all the academical titles. In the university of Paris, where this as well as the other learned distinctions appears to have originated, it was originally a mere title, belonging to those who taught in the schools (magistri, doctores). Thus every master was, of necessity, a lecturer. In process of time (and probably about the middle of the 13th century) the title became a degree, attainable by all after a certain amount of residence and proficiency; while the duty of lecturing was confined only to a certain number of masters, termed *regents*. About the same period the separation of the degrees of master and doctor took place. In the English universities, the degree of master of arts follows that of bachelor. A master becomes a regent after a short period; and, according to the old academical constitution, is supposed to read lectures during the year of his regency. On becoming a regent, he becomes a member of the governing body of the university; having a vote in congregation and convocation at Oxford, in the senate at Cambridge. In our universities the degree of master is the highest in the faculty of arts; but subordinate to that of bachelor of divinity. Elsewhere the faculty of arts is synonymous with that of philosophy, in which the degree of doctorate is conferred, superior to that of master.

MASTER, otherwise called Captain, in Commercial Navigation, the person entrusted with the care and navigation of a ship. His duties are very important. In some countries no one can be appointed to this office who has not been declared to fill it by a legally constituted board; but in this country the owners are left to their own discretion as to the skill and honesty of the master; and although he is bound to make good any damage that may happen to the ship and cargo by his negligence or unskilfulness, he cannot be punished as a criminal for mere incompetence. No one is qualified to be the master of a British ship unless he be a natural-born British subject, or naturalized by act of parliament; or have become a subject to his majesty by conquest, cession, &c., and have taken the oaths of allegiance; or a foreign seaman who has served three years in time of war on board of his majesty's ships.

MASTER. In the Royal Navy, the officer who has the charge of the navigation of the ship, with other duties: his rank is next to lieutenant.

MASTER ATTENDANT. The officer next in rank to the superintendent of the royal dock-yard.

MASTER AT ARMS. A petty officer of the navy, who is, in fact, the head of the police of the ship: his assistants are called ship's corporals.

MASTER OF THE CEREMONIES. An officer attached to all European courts, whose duty consists in regulating all matters of etiquette and state ceremony. (*See* CEREMONIES, &c.) The name is also applied to any individual who is appointed by general consent to preside over the arrangements of a public ball, with the power of deciding all disputes that may arise therein.

MASTER OF THE HORSE. The third great officer in the British court. When not put in commission, this office is always filled by a nobleman. He has the management of all the royal stables and bred horses, with authority over all the equerries and pages, coachmen, footmen, grooms, &c. In solemn cavalcades he rides next the sovereign. Salary, 1276*l*. 13*s*. 4*d*. per annum. The queen dowager's household has also a master of the horse and three equerries.

MASTER OF THE HOUSEHOLD. An officer employed under the treasurer of the household to survey accounts.

MASTER OF THE MINT. *See* MINT.

MASTER OF THE ROBES. An officer of the royal household, in the lord chamberlain's department. His salary is 800*l*. per annum.

MASTER OF THE ROLLS. *See* MASTERS IN CHANCERY.

MASTERS IN CHANCERY, are assistants to the lord chancellor. The masters in ordinary are twelve in number, of whom the master of the rolls is chief. To them are referred interlocutory orders for stating accounts, computing damages, &c. They also administer oaths, take affidavits and acknowledgments, and examine bills in chancery with reference to their propriety. The masters are also employed by the house of peers in carrying messages to the commons. Masters extraordinary are appointed to act in the country beyond twenty miles from London. By 3 & 4 W. 4. c. 94. s. 16., the appointment of masters in ordinary is taken from the lord chancellor, and vested in the crown.

MA'STER-SI'NGERS. A class of poets who flourished in Germany during the 15th and part of the 16th century. They were confined to a few imperial towns, and their chief seat was the city of Nuremberg. They were generally of burgher extraction; and formed regular corporations, into which proficients were admitted by the ordinary course of apprenticeship. Their poetry (generally confined to devotional or scriptural pieces, legendary tales, with some admixture of satire and of amatory lyrics) was subjected to a peculiar and pedantic code of laws, both composition and versification; and a board of judges (styled merker) assembled to hear the poems recited, and *mark* the faults which might be committed in either particular: he who had the fewest faults received the prize. Hans Sachs, the famous cobbler of Nuremberg, was a member of these societies; although his genius was of too independent a character to submit to the trammels of their poetical regulations.

MA'STIC. (Gr. μαστιχη, *a species of gum.*) In Architecture, a cement of recent introduction into England,

employed for plastering walls. It is used with a considerable portion of linseed oil, and sets hard in a few days. From this latter circumstance, and from its being fit for the reception of paint at an early period, it is much used in works where great expedition is requisite.

MASTIC. A peculiar resin which exudes from the *Pistacia lentiscus*. Its chief use is in varnishes.

MA'STICOT. (Fr. massicot.) In Painting, a yellow colour, being an oxide of lead.

MASTI'TIS. (Gr. μαστος, *the breast*.) Inflammation of the breast in women: it commonly terminates in suppuration.

MA'STODON. (Gr. μαστος, *a nipple*, and οδους, *tooth*.) A genus of extinct fossil quadrupeds allied to the elephant; so called from the conical projections upon the surfaces of the molar teeth.

MA'STOID. (Gr. μαστος, and ειδος, *form*.) Certain *nipple-like* protuberances of the bones.

MASTOTHE'CA. (Gr. μαστος, and θηκη, *a receptacle*.) A name sometimes used for Marsupium, and applied to the abdominal pouch of the marsupial animals.

MATE. In a Merchant Ship, the deputy of the master, taking in his absence the command. There are sometimes only one, and sometimes two, three, or four mates in a merchantman, according to her size; denominated 1st, 2d, 3d, &c. mates. The law, however, recognizes only two descriptions of persons in a merchantman — the master and mariners; the mates being included in the latter, and the captain being responsible for their proceedings.

In men-of-war, the officers immediately subordinate to the captain are called lieutenants. But the *master*, or officer whose peculiar duty it is to take charge of the navigation of the ship, has certain mates under him, selected from the midshipmen. The boatswain, gunner, carpenter, &c. have each their mates or deputies, taken from the crew.

The officers subordinate to the commander in the ships belonging to the East India Company were called 1st, 2d, 3d, &c. officers. East Indiamen had no sailing masters, the commanders performing that duty. (*Falconer's Marine Dictionary*, &c.)

MATÉ. The Paraguay name of a plant called *Ilex paraguensis* by botanists, whose leaves are used extensively in that country as a substitute for tea. It has the property of turning milk blackish when mixed with it.

MATE'RIAL. Any thing composed of matter, or possessing the fundamental properties of matter. See MATTER.

MATE'RIALISM. That metaphysical theory which is founded on the hypothesis that all existence may be resolved into a modification of matter, including, of course, the conscious subject. Materialists, of one sort or other, have abounded in every stage of philosophical thought. They have consisted, in the main, of persons accustomed to the exclusive pursuit of merely physical or empirical science, who have transferred the habits and prejudices thus engendered to the higher sciences of metaphysics and physiology. The most celebrated materialists were, among the ancients, Democritus and his later disciples; Epicurus and his sect; to whom may be added, though in a somewhat different sense, the Stoics: among the moderns, Gassendi, Hobbes, Hartley, and Dr. Priestley. Most schemes of materialism rest on the assumption that all that is real in nature consists in the minute particles from the juxtaposition of which all sensible objects arise. This is what is variously designated as the atomic, the mechanical, or the mechanico-corpuscular theory, and has met with supporters chiefly in France. Among ourselves, in very recent times, Dr. Thomas Brown has eloquently maintained that part of this system which relates to physical phenomena; though he has combatted, with the utmost subtlety and ingenuity, the portion of it which includes the nature of the mind itself. (Compare sect. v—ix. with sect. xii—xiv. See also *Priestley's Disquisitions on Matter and Spirit*, 1777; and his *Three Dissertations on the Doctrine of Materialism and Philosophical Necessity*. Also, *Price's Letters on Materialism and Philosophical Necessity*.) The latest and boldest defence of materialism that has appeared in England is to be found in the celebrated lectures of Mr. Lawrence, who maintained that the brain is to be conceived as secreting thought, in the same sense in which the liver secretes bile or the stomach the gastric juice.

MATE'RIA MEDICA. This term implies the various substances, natural and artificial, which are used in the cure of disease, and which are usually called *medicines*. They are frequently arranged into classes dependent upon their virtues or effects, or upon their constituent parts: but perhaps the most convenient arrangement is the alphabetical.

MATHEMA'TICS. (Gr. μαθησις, *learning*.) The science which investigates the consequences which are logically deducible from any given or admitted relations between magnitudes or numbers. It is usually divided into two parts: *pure*, where geometrical magnitude or numbers are the subject of investigation; and *mixed*, where the deductions thus made are from relations which are obtained by observation and experiment from the phenomena of material nature, and which constitutes what is otherwise called *physics*, or physical science.

The first object of mathematical science was geometry, and this received its highest degree of cultivation amongst the Greeks. Several of their works are come down to our own times, but all have undergone more or less of mutilation; and some of the most interesting are either wholly lost, as the *Porisms* of Euclid, or known to us only through the medium of Arabic translations, as the *Sectio Rationis* of Apollonius. See GEOMETRY.

The next object of research that comes under the denomination of pure mathematics is number, the science of which constitutes arithmetic. By reason of their defective system of notation, the Greek geometers were under the necessity of employing very complicated methods for performing ordinary arithmetical calculations; and for investigating the more abstruse properties and relations of numbers they had recourse to geometrical constructions. The moderns have, however, discovered a much more simple and direct system of processes, constituting *algebra;* and this has also been applied with great success to the solution even of geometrical problems and thorems, which by purely geometrical methods had never been effected. The differential calculus and the calculus of functions are also branches of algebra. See ARITHMETIC and ALGEBRA.

Of the various branches of the mixed mathematics, or applied mathematics, astronomy is by far the most advanced towards perfection; and next to it the doctrine of optics, which has been cultivated as subservient to astronomy. This has depended chiefly on the simplicity of the *laws* which connect the phenomena, and the consequent simplicity of the mathematical investigations which are necessary for a development of their consequences. Nevertheless, simple as those laws are, and relatively simple as the investigations to which they lead also are, their perfect development is beyond the present powers of mathematical science, which in numerous cases can only furnish approximate results.

MA'TINS. In the Roman Catholic church, the earliest of the canonical hours of prayer. See HOURS.

MA'TRASS. A chemical vessel employed in sublimations, and in digesting solutions in a sand heat. It is superseded in the modern laboratory by a flask.

MATRI'CULA. (Lat. mater, *mother*.) A register kept of the admission of persons into any body of society, of which a list is made. In the Romish church there was a *matricula clericorum*, a list or catalogue of the officiating clergy; and *matricula pauperum*, a list of poor persons to be relieved. Hence, when a student is entered in the register of the universities, he is said to be *matriculated*.

MATRIMONY. See MARRIAGE.

MA'TRIX. (Lat.) In Medallurgy, the stony substance in which crystalline minerals and metals are embedded is frequently termed their *matrix* or *gangue*. In dyesinking the *matrix* is the indented mould from which impressions are taken in relief. Type-founders apply the term to the iron moulds in which the letters are cast.

MA'TTER. (Lat. materies.) Substance. Of the intimate nature of matter the human faculties cannot take cognizance; nor can data be furnished, by observation or experiment, on which to found an investigation of it. All we know, or ever can know of matter, is its *sensible properties*. Some of these are the foundation of physical science; others of the different subordinate sciences, as, for instance, of chemistry.

Matter is divisible by abrasion and other means into small fragments, which, when the division is carried to any considerable extent, are called particles. It is supposed, however, and many reasons appear to justify the hypothesis, that it is capable of reduction into particles (called atoms) of particular forms, and each class having its own proper magnitude and peculiar properties; that determinate numbers of atoms of one kind admit of combination with some determinate number of another kind, or of several kinds, and of thereby forming compounded atoms, having properties peculiar to that combination, and different from the *known* properties of their elemental atoms. These solutions and combinations result from properties inherent in the atoms themselves; but whether the simple classes of atoms that are believed to exist are themselves really primary and elemental is not known, and probably never can be with certainty.

In larger masses, or in masses of aggregated atoms, so classed that their peculiar properties are mutually neutralized, phenomena are exhibited which bear a great resemblance to one another through considerable classes of such compounds, whose elements we have reason to believe differ very considerably; and other properties are found to exist in all, and differing only in degree or intensity. These last are the subjects of *physical* investigation: they are called emphatically the properties of matter; and the laws of their mutual influences are the foundation of *mechanical philosophy*. These properties

may be regarded as either essential or contingent. The essential properties of matter are usually reckoned the following: —

1. *Divisibility*, or the property which every known substance possesses of being separable into parts, and these again into smaller parts, and so on until the parts become inappreciable to our senses; nor can any limit be placed to the subdivision.

2. *Impenetrability*, or a resistance exerted by every body to the occupation of its place by another. This resistance is of various degrees of intensity, dependent on the state and atomic composition of the bodies; but no two bodies can simultaneously occupy the same place.

3. *Porosity*, or the separation of the particles or atoms from each other by intervals or pores. Every substance with which we are acquainted is more or less porous.

4. *Compressibility*, or the property in virtue of which the volume of every body may be contracted into smaller dimensions.

Among the essential properties of matter may also be included *extension* and *figure;* but these belong also to space, and form the subject of geometry.

The contingent properties of matter are *mobility* and *weight*. Matter in every form is capable of being moved from one place to another; and every substance gravitates towards the centre of the earth. But motion has reference to space, and weight to the attraction of other matter.

The above are the general properties of matter, upon which physical investigations depend. There are, however, various other qualities belonging to particular substances, or to matter in particular states, the consideration of which is important in mechanical philosophy. Among these the principal are *elasticity*, *fluidity*, *hardness*, *rigidity*, *solidity*, — for which see the respective terms.

MAU'NDRIL. In Coal Mines, a pick with two shanks.

MAUNDY THURSDAY. The Thursday preceding Easter, on which the sovereign of England distributes alms to a certain number of poor persons at Whitehall; so named from the maunds or baskets in which the gifts were formerly contained. (*See* SHERE THURSDAY.) This custom is of very great antiquity; and, according to Ducange, it derives its origin from St. Augustine. (See *Nare's Glossary; Fosbrooke's Encyc. of Antiquities*, p. 702.)

MAUR, SAINT, CONGREGATION OF. A learned body of religious of the Benedictine order; so called from a village near Paris, where they were established in 1618. On the request of Louis XIII., Gregory XV. gave this order his approval by an apostolical brief, dated 17th of May, 1621; and it obtained new privileges from Urban VIII., by a bull dated 21st of Jan. 1627. The fame of this body attracted the attention of many other religious orders, several of which were induced to submit to its rules; and at last it numbered upwards of a hundred religious houses. The literary world owes to them a series of very valuable editions of ancient Greek authors, chiefly fathers, during the 17th century. Among the most eminent of its members during that period may be mentioned Jean Mabillon, Thierri Ruinart, Hugh Menard, and Bernard de Montfaucon, &c. &c. (See Mosheim, *Eccl. Hist.* vol. v.)

MAUSOLE'UM. A sepulchral building; so called from Mausolus, king of Caria, to whose memory it was raised by his wife Artemisia, about 353 B.C.: hence all sepulchral structures of importance have obtained the name of mausolea. From its extraordinary magnificence it was esteemed the seventh wonder of the world. According to Pliny, it was one hundred and eleven feet in circumference, and one hundred and forty feet high. It is said to have been encompassed by thirty-six columns, and exceedingly enriched with sculpture.

MAXI'LLA. (Lat. maxilla, *a jaw.*) In Anatomy, this term is applied to the bones supporting the teeth of both jaws. In Zoology, it is restricted to the upper jaw in Mammalia, and to the inferior pair of horizontal jaws in articulate animals.

MA'XIM. Synonymous with *axiom*, which see.

MA'XIMA AND MINIMA. Terms employed in analysis to signify not the absolute greatest and least values of a variable quantity, but the values it has at the instant when it ceases to increase and begins to decrease, or *vice versâ*. A variable quantity may therefore have several maxima and minima. The theory of maxima and minima forms a part of the differential calculus, and is accordingly given in all works on that subject.

MAY. The fifth month of our year, but the third of the Roman. The name is supposed to be derived from Maia, the mother of Mercury, to whom the Romans offered sacrifices on the first day of the month; but various other derivations have been assigned to it. *See* CALENDAR.

MAY DAY. The 1st of May is usually so called in England, by way of eminence, in commemoration of the festivities which from a very early period were till recently, and in many parts of the country are still observed on that day. It would be out of place in this work to give any detailed account of them, as they are universally known; but a few words as to their origin may not be out of place. In looking at the nature of these rites, which are to a certain extent common to every place in which they are observed, it is evident that they had their origin in the heathen observances practised in honour of the Latin goddess Flora; but it is impossible to fix with accuracy the precise period at which they were introduced into England. The earliest notice of the celebration of May-day may be traced to the Druids, who on May-eve were accustomed to light large fires on eminences in gratitude and joy for the return of spring. At a later period the observance of this day appears not to have been peculiar to any class of society, for the most exalted as well as the lowest persons took part in it. In his *Court of Love* Chaucer says, that on this day "forth goeth all the court, most and least, to fetch the flowres fresh, and braunch and bloom;" and it is well known that Henry VIII. and Katherine and all their court partook in the diversion. The *maypole*, which is still visible in many of the English villages, and *Jack in the green* are still relics of this custom. (Some interesting remarks on this subject are to be found in *Grimm's Deutsche Mythologie*, pp. 448—451.)

MAYOR. (Lat. major, meaning the first or senior alderman.) The title of the chief municipal officer of a borough, to whom it appears to have been first given by charters granted some time after the Conquest. But the title and office of portreeve or boroughreeve still continued, in some few places to the exclusion of, and in some others in conjunction with, that of mayor, until the passing of the Municipal Reform Bill, 5 & 6 W. 4., by which the latter title was applied universally and exclusively to every borough. The chief magistrates of London and Dublin are designated Lord Mayor.

MAYOR. (Maire.) In France, the first municipal officer of each commune, according to a general system established by the law of 14th Dec. 1789, which created municipalities. Since 1831 they are selected by the crown out of the municipal council, which is chosen by the electoral body. The maire has one or more *adjuncts* or assessors, according to the population of the commune, chosen in the same manner. The maire keeps the registers of births, marriages, &c. of the commune; he acts as a magistrate in the apprehension and commitment of offenders; he has also a judicial power over certain minor offences. He is also the principal agent of the general administration for his commune, and the executive authority to carry into effect the ordinances of the municipal council.

MAYORA'ZGO. (Span., from Lat. magistratus. *See* MAJORAT.) Strictly, the right possessed by the eldest born in noble families to inherit certain property on condition of transmitting it entire to those possessed of the same right on his decease. Five distinct species of mayorazgo, or right of hereditary succession, are now known in Spanish law. Property held in virtue of the right cannot be alienated or disposed of. The mischievous effects of this strict system of entail on agriculture and national wealth, and on the character of the higher classes of Spain, have been long insisted on by political philosophers.

MAYOR OF THE PALACE. (Lat. major domus regiæ.) In early French History, the title of the chief officer of state under the Merovingian kings. After the death of Dagobert I., A.D. 638, and in the subsequent decay of the royal authority, these functionaries by degrees usurped almost the entire power of the state. The first of those mayors who exercised this kind of sovereignty was Grimoald, under Sigebert III., king of Austraria. Pepin, son of Charles Martel, having succeeded his father in the office of mayor of the palace, afterwards ascended the throne in 752; after which time the office lost its importance, or was altogether abolished. (See Turner, *Hist. of England in the Middle Ages*, vol. i. p. 8.)

MEAD. (Dutch, meede.) A vinous liquor made by dissolving one part of honey in three of boiling water, flavouring it with spices, and adding a portion of ground malt and a piece of toast dipped in yeast, and suffering the whole to ferment. The Scandinavian mead is flavoured with primrose blossoms. Mead formed the ancient, and for centuries the favourite beverage, of the northern nations. It is frequently mentioned in *Ossian.*

MEA'DOW. A flat surface under grass, generally on the banks of a river or lake; but so far above the surface of the water as to be considerably drier than marsh land, and, consequently, to produce grass and herbage of a superior quality. The soil of meadow lands is generally alluvial, and more or less mixed with sand; and it is kept in a state of fertility by the depositions made on its surface, in consequence of being occasionally overflowed by the adjoining river or lake. The produce of meadows is generally made into hay, which, though not equal in quality to that produced on drier grass lands, is yet superior to what is obtained from marshes.

MEAN. In Mathematics, a quantity having an inter-

mediate value between several others which are formed according to any *assigned law* of succession.

The *arithmetical mean* of several quantities is simply the *average* formed by dividing the sum of all the quantities by their number. In physical inquiries, where a great number of values of a quantity have been determined by observation or experiments, of which the error is as likely to be in excess as defect, the average or arithmetical mean is the most probable result.

The *geometrical mean* between two quantities, or the *mean proportional*, is a quantity which forms the middle term of a duplicate ratio, or continued proportion of three terms: viz. such that the first given term is to the quantity sought as that quantity is to the other given term. In arithmetic, it is the square root of the product of the two given terms.

The *harmonical mean* is such a number that, the first and third terms being given, the first is to the third as the difference of the first and second is to the difference of the second and third: or, if a, b, c be the numbers, b being the mean,—

$$b=\frac{2\,a\,c}{a+c}, \quad \text{or} \quad \frac{2}{b}=\frac{1}{a}+\frac{1}{c}.$$

ME'ASLES. *See* RUBEOLA.

MEA'SURE. (Lat. mensura.) In Geometry, a magnitude or quantity taken as unit, and employed to express the relations of other magnitudes or quantities of the same kind. Euclid defines the measure of a quantity to be that which, being repeated a certain number of times, becomes equal to the quantity measured. Thus, in Arithmetic, the *measure of a number* is any number which divides the given number without leaving a remainder; but this definition rather corresponds to the notion of *aliquot part*.

In a general sense, the term measure is applied to that by which any thing is compared in respect of quantity. Thus, we have measures of extension, of weight, time, force, resistance, temperature, &c.; in short, of every thing of which greater and less can be predicated; and it frequently happens that the unit or measure is not taken in the thing or property which is the immediate subject of consideration, but in something else which depends on it, or is proportional to it. Angular space, for example, is measured by an arc of a circle; time, by the rotation of the earth about its axis, or its revolution about the sun; force, by the quantity of motion it impresses on a body; degrees of heat, by the expansion of metals or other substances; muscular strength, by the resistance of a spring, &c. *See* ANGLE, CHRONOLOGY, GRAVITY, THERMOMETER, DYNAMOMETER, &c.

By measure, in an absolute sense, is understood the unit or standard by which we measure extension. We have, therefore, measures of length, of superficies, and of volume or capacity; but, as the two latter may be deduced in all cases from the former, it is only necessary to establish a unit, or standard of length. The choice of such a standard, and the different multiples and parts of it taken for the uses of society, form a metrical system, or system of metrology.

Standards of Measure.—As no precise notion can be formed of the magnitude of a line in any other way than by comparing it with another line of a known length, the necessity of having recourse, for the interchange of ideas, to measures not entirely arbitrary, but fixed by nature, and intelligible alike to all mankind, seems to have been perceived in the earliest ages. Hence originated the *foot*, the *cubit*, the *span*, the *fathom*, the *barleycorn*, the *hair's-breadth*, and other denominations of measure, taken from parts of the human body, or from natural objects, which, though not of an absolute and invariable length, have a certain mean value sufficiently definite to answer all the purposes required in a rude state of society. But, as civilization advanced, the necessity of adopting more precise standards would be felt, and the inadequacy of such measures as the foot, the cubit, &c. (referred only to the human body) to convey accurate notions, would be rendered most apparent in their application to itinerary measures, or the estimation of great distances; where differences of the fundamental measure, of no account when one or two units only are taken into consideration, would amount, by repeated multiplication, to enormous quantities. In order to avoid this inconvenience, recourse was had to other methods of estimation; but which, in fact, amounted only to descriptions more or less vague, and not to measures. Thus, in ancient authors, we frequently read of a day's journey, a day's sail, and so forth; and in many parts of the continent of Europe, even at the present time, it is the custom of the peasantry to reckon itinerary distances by hours.

On looking among the objects of nature for a standard of measure perfectly definite, and, at the same time, invariable, and accessible to all mankind, a very slender acquaintance with geometry and natural philosophy will suffice to show that the subject is beset with innumerable difficulties. In fact, nature presents only two or three elements which, with the aid of profound science and a refined knowledge of the arts, can be made subservient to the purpose; and none at all which are applicable without such aid. The earth is nearly a solid of revolution, and its form and absolute magnitude are presumed to remain the same in all ages: hence the distance between the equator and the pole is an invariable quantity; and any assigned part of that distance, as the 90th, or a degree of the meridian, is constant, and will furnish a precise and unalterable standard of measures, fit for the purposes of metrology, provided we have the means of comparing it with the rods or scales which must necessarily be used in comparing distances, or the magnitudes of bodies. The force of gravity at the earth's surface is constant at any given place, and very nearly the same at all places under the same parallel of latitude and at the same height above the level of the sea; hence the length of a pendulum which makes a given number of oscillations in a day is also constant at a given place, and, with proper skill and precautions, may be determined in terms of any assumed scale. These two elements, the length of a degree of the meridian, and the length of the seconds' pendulum, are the only ones furnished by nature which have yet been used as the basis of a system of measures. One or two others have been suggested, as the height through which a heavy body falls in a second of time, determined, like the length of the pendulum, by the force of gravity; or the perpendicular height through which a barometer must be carried till the mercurial column sinks a determinate part—for example, a 30th of its own length; but, for reasons which it is unnecessary here to state, these distances are not so susceptible of being accurately determined as the terrestrial degree, or the length of the seconds' pendulum.

It has been supposed (Paucton, *Metrologie;* Bailly, *Histoire de l'Astronomie ancienne*) that some ancient nations referred their measures of length to a unit chosen from an aliquot part of the earth's circumference, and that the different *stadia* were only different aliquot parts of the same great unit; but the supposition is altogether improbable, for the ancients had no means of determining the magnitude of the earth with any tolerable precision, and do not themselves make any reference to such a standard. Mouton, an astronomer of Lyons, about 1670, proposed as a universal standard of measure a *geometrical foot*, of which a degree of the earth's circumference should contain 600,000; and remarked that a pendulum of this length would make $3959\frac{1}{3}$ vibrations in a half hour. In 1671 Picard proposed a similar idea; and Huygens first suggested the pendulum as the unit or standard of measures. Condamine, one of the French academicians engaged in the measurement of the terrestrial arc in Peru, proposed that the equatorial pendulum ought to be adopted, as being the most natural measure, and independent of the pretensions of different countries. No attempt, however, was made to establish a regular system of measures on any of these standards until the time of the French revolution, when a system of weights and measures, referred to the terrestrial degree, and accommodated to our arithmetical scale, was adopted in that country.

English Standard Measures.—The unit of lineal measure in this country is the yard, all other denominations being either multiples or aliquot parts of the yard. But as this is an entirely arbitrary measure, and, until the year 1824, was never strictly defined by the legislature, great perplexity has often arisen in attempting to ascertain the exact portion of space it was meant to represent. For the purpose of preserving some degree of uniformity among the ordinary measures of the kingdom, certain standards were preserved in the exchequer, with which all rods were required to be compared before they were stamped as legal measures. The oldest of these standards in existence dates from the reign of Henry VII.; but it has long been disused; and that which, till the year 1824, was considered as the legal standard, was a brass rod, of the breadth and thickness of about half an inch, placed there in the time of Elizabeth. There was another similar rod of the same date, called an *ell*. The ell, however, does not appear ever to have been established as a legal measure; but was conventionally considered as equal to a yard and a quarter. To these rods belonged a brass bar, on one edge of which was a hollow bed or matrix fitted to receive the square rod of a yard, and on another a like bed fitted to receive that of an ell; and into these beds were fitted the yard and ell measures brought to be examined and stamped with the standard marks. All rods so stamped became standard measures. It is abundantly obvious that measures determined in this coarse manner could have no strict claim to be considered as *accurate* copies of the original standard; but it would seem that the standard itself was incapable of affording any definite or correct measure. It is thus described by Mr. Baily, in his Report on the new Standard Scale of the Royal Astronomical Society:—"I have had an opportunity of seeing this curious instrument, of which it is impossible, at the present day, to speak too much in derision or contempt. A common kitchen poker, filed at the ends in the rudest manner, by the most bungling

workmen, would make as good a standard. It has been broken asunder, and the two pieces been dovetailed together, but so badly that the joint is nearly as loose as that of a pair of tongs; and yet till within the last ten years, to the disgrace of this country, copies of this measure have been circulated all over Europe and America, with a parchment document accompanying them, certifying that they are true copies of the English standard." (*Memoirs Roy. Astr. Soc.* vol. ix.)

Such being the condition of the legal standard, it was obviously impossible that any measure could be found in terms of it, where great accuracy and minuteness were necessary; for instance, that of the seconds' pendulum, or a degree of the meridian. In fact, it was utterly inapplicable to any scientific purpose whatever. In the year 1742 some Fellows of the Royal Society, and Members of the Academy of Sciences at Paris, proposed to have accurate standards of the measures and weights of both nations made and carefully examined, in order that a means might be provided of comparing the results of scientific experiments in England and France. The committee who undertook the matter, besides the legal standard in the Exchequer, found some others which were considered of good if not equal authority. At Guildhall they found two standards of long measure, which were only two beds or matrices, one of a yard, and the other of an ell, cut out of the edges of a substantial brass bar, like that at the Exchequer. Another, preserved in the Tower of London, was a solid brass rod, about 7-10ths of an inch square, and 41 inches long; on one side of which was the measure of a yard, divided into inches. Another, belonging to the clockmakers' company, delivered to that corporation by indenture from the Exchequer in 1671, was a brass rod of eight sides, nearly half an inch thick, on which the length of the yard was expressed by the distance between two upright pins, or small checks, filed away to the proper quantity. The committee selected the standard in the Tower, as being the best defined, and consequently the best adapted to their purpose; and Mr. George Graham (a celebrated clockmaker), at their desire, laid off from it, with great care, the length of the yard on two brass rods, which were then sent to the Academy of Sciences at Paris, who in like manner set off thereon the measure of the Paris half toise. One of these was kept at Paris, the other was returned to the Royal Society, where it still remains: but, unfortunately, it was not stated at what temperature the toise was set off; and, consequently, the comparison is now of little or no value.

In 1758 a committee of the House of Commons was appointed to inquire into the original standards of weights and measures in the kingdom. The committee entered very fully into the subject, and presented to the house an elaborate report, in which they recommended that a rod which, at their order, had been made by Mr. Bird from that of the Royal Society, and marked "Standard Yard, 1758," should be declared the legal standard of all measures of length. This rod consisted of a solid brass bar, 1·01 inch square and 39·06 inches long. At about 1½ inch from each end a gold pin or stud is inserted; in which pins, at the distance of 36 inches, are two points, intended to designate the length of the yard. It was proposed that this rod should be carefully laid up in safe custody, to be used only occasionally; and, for the ordinary sizing of yards, another rod was prepared by the same artist, furnished with cheeks, and divided into inches and parts, for the easier adjusting of any comparative measure.

In the following year another committee was formed on the subject. It concurred in the recommendation of the former committee, that Bird's standard yard should be the only unit of lineal measure; and at the same time recommended that a copy of it should be made, for security against accidents, and deposited in some public office. Accordingly, a second standard was constructed by Bird, in 1760, similar to the former, of which, indeed, it was intended to be a copy. This last standard (of 1760) was declared by the act of 1824 to be the legal standard of the kingdom.

Notwithstanding these two parliamentary reports, no legislative enactment was passed, and the subject remained for a long time in the same state of uncertainty. In 1796 a scale was constructed by the celebrated Troughton, for Sir George Shuckburgh, which has been much referred to in scientific treatises, in consequence of its having been used in the experiments made by Captain Kater for determining the length of the pendulum; and also carefully compared with all the other standards, and with the French mètre. Troughton at several times made various other measures; but, as they never possessed any legal authority, it is unnecessary to allude to them farther than to state that they were all copies, as nearly as could be made, of a scale that had been constructed by Bird, and had belonged to Mr. Harris, assay-master at the Mint.

In 1814 the subject of standard measures and weights was again brought under the consideration of parliament; and a committee of the House of Commons made a report, which, however, was attended by no result. In 1819 a commission was named by the prince regent, consisting of Sir Joseph Banks, Sir George Clerk, Mr. Davies Gilbert, Dr. Wollaston, Dr. Young, and Captain Kater, who first recommended that, for the legal determination of the standard yard, the yard which had been employed by General Roy, in the measurement of a base on Hounslow Heath as a foundation of the trigonometrical survey, should be adopted; but in a subsequent report, made the following year (1820), they proposed the standard which had been made by Bird in 1760, on account of its being, as they stated, "both laid down in the most accurate manner, and as best agreeing with the most extensive comparisons which have been hitherto executed by various observers and circulated throughout Europe, and in particular with the scale employed by the late Sir George Shuckburgh." This last report having been approved by a committee of the Commons, an act was at length passed, in June, 1824, in which the unit of measure was for the first time defined, and in the following terms:—

"The straight line or distance between the centres of the two points in the gold studs in the brass rod, now in the custody of the clerk of the House of Commons, whereon the words and figures *Standard Yard*, 1760, are engraved, shall be, and the same is hereby declared to be, the original and genuine standard of that measure of length or lineal extension called a yard; and that the same straight line or distance between the centres of the said two points in the said gold studs in the said brass rod, the brass being at the temperature of 62° of Fahrenheit's thermometer, shall be and is hereby denominated the *Imperial Standard Yard*, and, shall be and is hereby declared to be, the *unit* or only standard measure of extension." And the act further declared, that if at any time hereafter the said imperial standard yard shall be lost, or shall be in any manner destroyed, defaced, or otherwise injured, it shall be restored by making, under the directions of the lords of the treasury, a new standard yard, bearing the proportion to a pendulum vibrating seconds of mean time, in the latitude of London, in a vacuum, and at the level of the sea, as 36 inches to 39·1393 inches.

The recommendation of the commissioners, on which this enactment was founded, has been severely criticised; and, in point of fact, so far as the exact length of the yard is concerned, the subject remained in the same doubtful state in which it was before the act was passed. That the standard which was adopted was not an original measure (it was, in fact, a copy of Bird's standard of 1758, which was a copy of that of the Royal Society, which again was a copy of that in the Tower) was of little consequence, provided the measure had been laid down on it with such precision as to leave no doubt as to its exact length; but so far was this from being the case, that when it came to be compared with a new standard scale made for the Royal Astronomical Society, it was found to be utterly impossible to ascertain the centres of the points in the gold studs within distances perfectly appreciable by the methods of observation now practised. Mr. Baily, in his report above cited, says the mean diameter of each of the holes was nearly 100th of an inch; and they by no means presented any thing like a circular shape. In fact, not only did different persons differ in their estimate of the centres, but the same persons also differed at different times, according to the degree or direction of the light that impinged on the sides of the holes. And he adds, "How the legislature of the present day, when the art of making mathematical instruments has arrived at such a state of perfection, could have sanctioned the adoption of such an imperfect and undefinable measure as this for a standard, must always be a matter of astonishment; more especially when we consider that the French had recently set us a laudable example, in the great pains and labour taken in the execution of a new set of standard weights and measures of superior accuracy and precision." (*Mem. R. A. S.* vol. vii.)

This scale was destroyed by the fire which consumed the two houses of parliament in 1834; so that the country is at the present time without a legal standard, for the provision of the act relative to its restoration by comparison with the seconds' pendulum is perfectly nugatory. Its restoration could not be thus effected with any tolerable certainty. The length of the seconds' pendulum is one of those constants of nature which it is possible to determine only within certain limits; very narrow indeed, but still too wide for the purpose in question. Besides, the standard adopted by the legislature had never been directly compared with the pendulum; and the relation between them assigned in the act, namely, 36 to 39·1393, is now known to be incorrect, on account of the neglect of certain precautions in the determination of the length of the pendulum which subsequent experiments have shown to be indispensable. Accident has, however, given the means of effecting what the legislative enactment would have failed to do. Early

in the year 1834 a most laborious and minute comparison of the different standard measures was made with a new scale constructed for the Royal Astronomical Society. The length of the legal standard, as nearly as it could be determined, is known in terms of this scale, and may therefore be recovered; but, as a new act is necessary in any case, the legislature may probably be advised to do now what ought to have been done in the first instance, namely, cause a standard to be made in a more skilful manner, and authenticated copies of it, or rather other measures having ascertained relations to it, to be deposited in several public places, and only to be used in cases of emergency. The evil in this, as in many other instances, has arisen from legislating too much. All that is required is that two very fine points be struck in a strong rod of platinum, or a block of cast iron, at any convenient distance; and to declare that the distance between those points, at a given temperature of the metal, shall be the standard of measure, and that so many parts of this standard shall constitute the yard or unit: all the rest may be safely left to experimental philosophers and mathematical-instrument makers.

English System of Lineal Measures.—The unit of measure, as already stated, is the yard. The yard is divided into 3 feet, and the foot subdivided into 12 inches. The multiples of the yard are the pole or perch, the furlong, and the mile; $5\frac{1}{2}$ yards being a pole, 40 poles a furlong, and 8 furlongs a mile. But the pole and furlong are now scarcely ever used, itinerary distances being reckoned in miles and yards. The relations of these different denominations are exhibited in the following table:—

In.	Feet.	Yards.	Poles.	Furlongs.	Miles.
1	0·083	0·028	0·00505	0·00012626	0·0000157828
12	1	0·333	0·06060	0·00151515	0·00018939
36	3	1	0·1818	0·004545	0·00056818
198	16·5	5·5	1	0·025	0·003125
7920	660	220	40	1	0·125
63360	5280	1760	320	8	1

Measures of Superficies.—In square measure the yard is subdivided as in general measure into *feet* and *inches;* 144 square inches being equal to a square foot, and 9 square feet to a square yard. For land measure the multiples of the yard are the *pole*, the *rood*, and the *acre;* $30\frac{1}{4}$ (the square of $5\frac{1}{2}$) square yards being a pole, 40 poles a rood, and 4 roods an acre. Very large surfaces, as of whole countries, are expressed in square miles. The following are the relations of square measure:—

Sq. Feet.	Sq. Yards.	Poles.	Roods.	Acres.
1	0·1111	0·00367309	0·000091827	0·000022957
9	1·	0·0330579	0·000826448	0·000206612
272·25	30·25	1	0·025	0·00625
10890	1210	40	1	0·25
43560	4840	160	4	1

Measures of Volume.—Solids are measured by cubic yards, feet, and inches; 1728 cubic inches making a cubic foot, and 27 cubic feet a cubic yard. For all sorts of liquids, corn, and other dry goods, the standard measure is declared by the act of 1824 to be the *imperial gallon*, the capacity of which is determined immediately by weight, and remotely by the standard of length, in the following manner:—According to the act, the imperial standard gallon contains 10 pounds avoirdupois weight of distilled water, weighed in air at the temperature of 62° Fahrenheit's thermometer, the barometer being at 30 inches. The pound avoirdupois contains 7000 troy grains; and it is declared that a cubic inch of distilled water (temperature 62°, barometer 30 inches) weighs 252·458 grains. Hence the contents of the imperial standard gallon are 277·274 cubic inches. The parts of the gallon are *quarts* and *pints;* 2 pints being a quart, and 4 quarts a gallon. Its multiples are the *peck*, the *bushel*, and the *quarter;* the peck being 2 gallons, the bushel 4 pecks, and the quarter 8 bushels. The following are the relations:—

Pints.	Quarts.	Gallons.	Pecks.	Bushels.	Quarters.
1	0·5	0·125	0·0625	0·015625	0·001953125
2	1	0·25	0·125	0·03125	0·00390625
8	4	1	0·5	0·125	0·015625
16	8	2	1	0·25	0·03125
64	32	8	4	1	0·125
512	256	64	32	8	1

For an account of the various other measures used in commerce, see the *Commercial Dictionary;* or *Colonel Pasley's Observations on the Measures, Weights, and Money used in this Country* (London, 1834), where a full description is given.

French System of Measures.—The French system of measures, introduced during the Revolution, has for its standard the length of a quadrant of the earth's meridian. The unit of measures of length is the *mètre*, which is a ten-millionth part of the quadrant. This length, deduced from the great trigonometrical measurement of the meridian from Dunkirk to Barcelona, is marked by two very fine parallel lines drawn on a bar of platinum, and preserved in the archives of the Academy of Sciences. From a comparison of the standards of this country with a copy of the mètre in the possession of the Royal Society, Captain Kater found the length of the mètre to be 39·37079 inches of the English standard. (*Phil. Trans.* 1818.) Mr. Baily found the length of the mètre to be 39·3696786 inches of the Royal Astronomical Society's scale (*Mem. R.A.S.*, vol. ix. p.133.), from which, by reducing to the imperial standard yard by the data given in the same memoir, the true length of the mètre is 39·370091 inches of the imperial yard. The comparison is, however, attended with some degree of uncertainty, from the circumstance that a reduction must be made for the expansion of the metals; the standard temperature of the English measures being 62° Fahrenheit, and that of the French measures 32°, or the temperature of melting ice.

In the French system the unit of superficial measure is the *are*, a surface of 10 mètres each way, or 100 square mètres. The unit of measures of capacity is the *litre*, a vessel containing the cube of a tenth part of the mètre, and equivalent to 0·220097 parts of the British imperial gallon. The standard temperature is that of melting ice. All the divisions and multiples of the units are decimal; and the principle of nomenclature adopted was to prefix the Greek numerals to the decimal multiples, and the Roman numerals to the decimal subdivisions.

The measures of length are,

Myriamètre	=	10000 mètres.
Kilomètre	=	1000
Hectomètre	=	100
Mètre	=	1
Décimètre	=	0·1
Centimètre	=	0·01
Millimètre	=	0·001

The measures of surface are,

Hectare	=	10000 sq. mètres.
Are	=	100
Centiare	=	1

The measures of capacity are,

Kilolitre	=	1000 litres.
Hectolitre	=	100
Decalitre	=	10
Litre	=	1
Decilitre	=	0·1
Centilitre	=	0·01

The unit of solid measure is the *stere* or cube of the mètre, equal to 35·31658 English cubic feet.

No system of metrology hitherto invented can be compared with this of the French in a scientific point of view; nevertheless the decimal subdivisions have been found unsuited to the purposes of retail traffic, to which, in fact, only a binary system, or the division of the unit into halves and quarters, seems applicable. Accordingly, it has been found necessary to permit a modified system for such purposes; so that there are, in fact, at present in France three different systems of measures: the ancient, which was never wholly abandoned; the decimal system; and a binary system, or *système usuel*, having the decimal standards for its basis, with binary divisions, to which the names of the ancient weights and measures are given, the word *usuel* being annexed to prevent confusion.

Of the different measures of length used in European countries, the foot is the most universally prevalent. We subjoin the relation between the foot of different countries and the English foot:—

			English foot.
Russian foot	-	-	= 1
Paris foot	-	-	= 1·065765
Prussian and Danish foot		-	= 1·029722
Bavarian foot	-	-	= 0·957561
Hanoverian foot	-	-	= 0·958333
Saxon foot	-	-	= 0·929118
Austrian foot	-	-	= 1·037128

Comparative tables of the measures used in different countries are given in various works: one of the most complete and convenient will be found in *Hulsse's Sämmlung Mathematischer Tafeln*, Leipzig, 1840. For further information on the subject of this article, see *Paucton's Metrologie ou Traité des Mésures*, Paris, 1780; *Kelly's Universal Cambist*, 1821. See also LEAGUE, MILE; and on the subject of weights, see WEIGHT.

MEA'SURE. In Music, the interval or space of time between raising and depressing the hand in a movement; being the same as *bar*. The measure is regulated according to the different values of the notes of a piece, by which the time assigned to each note is expressed. Semibreves, for instance, occupy one rise and one fall, called a whole measure.

MEA'SURES. In Geology, sometimes used as synonymous with beds or strata; as *coal measures*.

MECHANICAL CURVE. A curve of such a nature that the relation between the absciss and the ordinate cannot be expressed by an algebraic equation. Such curves are now more commonly called *transcendental curves*. See CURVE.

MECHA'NICAL PHILOSOPHY. The science of mechanics applied to physical inquiries.

MECHA'NICAL POWERS. *See* MACHINE.

MECHA'NICAL SOLU'TION OF A GEOMETRICAL PROBLEM. In the constructions of pure geometry only the ruler and compasses are allowed to be used; or, in other words, the constructions are required to be effected by means of straight lines and circles only. The ancient geometers soon discovered that there were many problems (as the duplication of the cube and the trisection of an angle, for instance) which could not be constructed by these means. They hence had recourse to other instruments (*machinæ*) to effect this purpose; and such solutions were distinguished from the geometrical ones by the term *mechanical*.

MECHA'NICS (Gr. μηχανη, *machine*), in Natural Philosophy, is the science which treats of forces and powers, and their action on bodies, either directly or by the intervention of machinery.

The theory of mechanics, which is a branch of mixed mathematics, is founded on an axiom or principle called the *law of inertia*, or Newton's *first law of motion*; namely, that a body must remain for ever in a state of rest, or in a state of uniform and rectilineal motion, if it be not disturbed by the action of an external cause. Theoretical mechanics is therefore divided into two parts: *statics*, which treats of the equilibrium of forces; and *dynamics*, which is the science of accelerating or retarding forces, and of the actions they produce. When the bodies under consideration are in the fluid state, these become respectively *hydrostatics*, and *hydrodynamics*, which are comprehended under *hydraulics*; and sometimes the terms *ærostatics* and *ærodynamics* are used to denote the corresponding divisions of pneumatics; but all these divisions are more frequently included under the general term *mechanics*.

Practical mechanics, or a knowledge of the effects of some of the mechanical powers, must have existed to some extent from the earliest ages of the world; but of the machines used by the ancients in their constructions, the oldest account which we possess is contained in the *Architecture* of Vitruvius. Archimedes, in his *Treatise De Æquiponderantibus*, first investigated theoretically the principles of equilibrium; and the same philosopher is celebrated for the mechanical contrivances by which, in the siege of Syracuse, he so long frustrated the efforts of the Roman army under Marcellus. During the eighteen centuries which succeeded the age of Archimedes, the theory of mechanics remained in the same state. Galileo laid the foundations of modern dynamics by his discovery of the law of accelerating forces, and by reducing the propositions of that science to mathematical formulæ. In the hands of Newton mechanics assumed a new form; and the discovery of the new analysis enabled mathematicians to complete what had been begun by Galileo, and to express all the effects of the actions of bodies on each other by analytical equations.

For points connected with the theory, see ACCELERATION, DYNAMICS, FORCE, STATICS, &c.; and for details, LEVER, PULLEY, WHEEL AND AXLE, &c. The best treatise on the subject is that of Poisson, *Traité de Mécanique*, 2d ed. 1833.

MECHA'NICS' INSTITUTES. The name given to the means by which instruction is communicated to tradesmen and mechanics in large towns throughout the British empire. These institutes may be safely said to owe their origin to Dr. Birkbeck, who, in 1800, delivered a course of lectures on natural philosophy and its application to the arts to an audience composed entirely of the mechanics of Glasgow; though it was not until after the lapse of twenty years that his idea was followed up. Institutions of this sort are at present established in almost every town in England whose population amounts to 10,000, and in some of much smaller number. They are supported partly by contributions, and partly by the subscription of the members. Short courses of lectures, illustrated with experiments, are given on the most popular and interesting branches of natural philosophy, and occasionally on departments of literature, moral philosophy, political economy, &c. Reading rooms are attached to the greater number of these institutions, which, speaking generally, are well attended. On the whole, we believe these establishments have been productive of considerable advantage. The instruction they supply is, no doubt, very flimsy and superficial; but it notwithstanding serves to expand and inform the minds of the auditors, and is probably the most suitable for them. An improvement in the system of school education, by qualifying the members of mechanics' institutes the better to appreciate accurate scientific discussions, would be the most likely, or rather perhaps the only means, by which to improve the lectures given at the institutions in question. (See *Stat. of Brit. Empire*, vol. ii. p. 359.)

ME'CHANISTS. Those philosophers who refer all the changes in the universe to the effect of merely *mechanical* forces, such as *impact*, *weight*, and the like. They are opposed to the dynamical philosophers, or those who assume a living and spontaneous power in nature, antecedent to and different from the phenomena present to the senses. *See* MATERIALISM.

MECHLO'IC ACID. A compound of meconia and chlorine.

MECHO'ACAN. (From the province of Mexico, whence it is brought.) The root of the *Convolvulus mechoacauna*: it is a purgative, and was formerly used as a substitute for jalap.

MECO'NIC ACID. (Gr. μηκων, *the poppy*.) The peculiar acid with which morphia is combined in opium. When pure, it forms small white crystals. Its aqueous solution forms a deep red colour with the persalts of iron, which therefore are good tests for it, both free and combined. The salts of this acid are termed *meconates*; those of lime, baryta, lead, and silver are white, and soluble in nitric acid. Meconic acid is constituted of 7 atoms of carbon = 42, 2 of hydrogen = 2, and 7 of oxygen = 56: its equivalent therefore is 100.

ME'CONIN. (Gr. μηκων.) A white fusible substance, procured from opium, and supposed to be a distinct principle. It is said that not more than from two to three grains of it are contained in a pound of opium; it seems doubtful whether it be an educt or a product.

MECO'NIUM. (Gr. μηκων.) Opium. The term is also applied to the excrement found in the lower part of the fœtal intestines.

ME'DAL. (Fr. medaille.) A piece of metal, in the shape of a coin, engraven with figures or devices, struck and distributed in memory of some person or event. Ancient coins, although intended for the purpose of circulation, are also commonly termed medals. *See* NUMISMATICS.

MEDA'LLION. (Fr.) In Numismatics, this name is appropriated to coins struck in Rome, and the provinces under the empire, which, in gold or silver, exceed in size the largest coins of which the name and value are known in those respective metals; viz. the aureus in gold, and the denarius in silver. It has been doubted whether they were intended for the purpose of circulation, or merely struck, like modern medals, to commemorate persons or events. *See* NUMISMATICS.

ME'DALLURGY. (Fr. medaille, and Gr. εργον, *work*.) The art of making and striking medals and coins. *See* NUMISMATICS.

ME'DIÆ. (Gr. μεδαι, *middle*.) The three letters *b*, *g*, and *d* (beta, gamma, delta) are so called in the Greek alphabet, as holding respectively a middle place between their several *tenues*, *p*, *k*, *t* (pi, kappa, tau), and aspirates, *ph*, *ch*, *th* (phi, chi, theta).

ME'DIANT. (Lat. medius.) In Music, the chord which is a major or minor third higher than the key note, according as the mode is major or minor.

ME'DIASTI'NUM. The duplicature of the pleura, which divides the cavity of the thorax into two parts.

ME'DIATISA'TION. The annexation of the smaller German sovereignties to larger contiguous states, which took place, on a large scale, after the dissolution of the German empire in 1806. The same thing had been done on various occasions during the continuance of the empire; and the dominions so annexed were said to be mediatised, *i. e.* made mediately instead of immediately dependent on the empire. The term was retained when the abolition of the German union had rendered it in strictness inappropriate. A few more were mediatised after the peace of 1815. See *Conv. Lex.*; and *Hawkins's Germany*, 1838, which contains a chapter on this subject.

MEDIA'TOR. A term applied to Jesus Christ, as interceding between God and man, and obtaining for the latter the remission of the punishment due to original and contracted sin. The divinity of our Saviour is argued from his mediatorial character: it seeming impossible to conceive that a mere man could efficaciously intercede by the sacrifice of himself for the sins of his fellow men. Those reasoners, therefore, who have arrived at the conclusion of the mere humanity of Christ, either expressly deny or essentially modify the idea of his mediatorial character.

ME'DIUM. In Physics, the substance or matter in which bodies exist, or through which they move in passing from one point to another. The resistance which different mediums oppose to bodies in motion is proportional to the respective densities of the mediums. Newton supposed the existence of a universal medium, or ether, infinitely more rare and subtile than air, and diffused through the whole creation. The modern discoveries of the propagation of light by undulation, and of the acceleration of some of the small comets, give great probability to this supposition.

ME'DLAR. (Corruption of Mespilar?) The fruit of the *Mespilus germanica*, a plant found wild in several parts of Central Europe. It is remarkable for the austerity of its fruit when first gathered, and for its total loss of that quality after a few weeks, when it becomes soft, brown, and sweet, — a condition which the French call *blessi*. Of the garden varieties the Dutch medlar is the finest as to size, and the Nottingham the most delicate

in flavour. In the eyes of a botanist the medlar is only a hawthorn berry of large size.

MEDU'LLARY RAYS. (Lat. medulla, *marrow.*) The vertical plates of cellular tissue which radiate from the centre of the stem of Exogenous plants, through the wood to the bark. They cause that appearance in timber which carpenters call silver grain, or flower of the wood.

MEDU'LLARY SHEATH, is a thin layer of vessels which surround the pulp of Exogenous plants, and thence extend into the leaves and parts of fructification.

MEDU'LLARY SUBSTANCE. The interior white portion of the brain. The *medulla oblongata* is a part of the brain, lying upon the basiliary process of the occipital bone, and formed by the junction of the crura of the brain and cerebellum: it terminates in the spinal marrow.

MEDU'LLIN. That form of *lignin* which constitutes the pith of certain plants, as the pith of the sunflower.

MEDU'SA. In Mythology, the chief of the Gorgons (which see); according to Hesiod, the eldest daughter of Celo and the sea god Phorcus. Various stories are related of this mythological personage; but her chief peculiarity was the power she possessed of turning all who looked upon her into stone. She was slain by Perseus, who placed her head in the shield of Minerva, where it continued to retain the same petrifying power as before.

MEDU'SA. In Zoology, a name given by Linnæus to a genus of marine animals, now forming an extensive tribe (*Medusaria*) in the class *Acalepha* of the Cuvierian system. The body is in the form of a gelatinous disk, more or less convex above, called the "umbel," from the centre of which, and from the margin, there depend in most of the species processes or filaments more or less numerous, and more or less elongated; whence the resemblance to the fabled monster which suggested the original generic term. The *Medusæ* are commonly known by the name of "sea-blubber," "jelly-fish," &c. They have a stomach or digestive cavity excavated in the centre of the disk, and opening externally either by a central and inferior crucial mouth, or continued into branched appendages, and receiving the nutriment by innumerable minute pores, analogous to the "stomata" of plants, or those root-like appendages. The digested fluid is conveyed by vessels from the stomach to an exquisite network or plexus situated on the under surface of the border of the disk, where it receives the influence of the atmosphere, and is fitted for assimilation. Some species, as the *Medusa aurita*, have also intestinal canals leading from the stomach to separate anal outlets. Traces of a nervous system and rudimental organs of vision have been discerned in some of the *Medusæ*. They swim by muscular contraction of the margins of the disk. They are of distinct sexes, which congregate together chiefly in the autumnal months. The male and female organs much resemble each other, and are situated, in both sexes, in corresponding cavities, generally four in number, on the under surface of the disk. The ova are received when impregnated in marsupial sacs appended to the arms (in *Medusa aurita*), whence they escape in the form of ciliated infusoria, afterwards assume the structure of eight-armed polypes, pass the winter in this state, and undergo their final transformation in spring. Notwithstanding the complication of the organic machinery, functions, and generative economy of the *Medusæ*, their solids form so small a proportion of their frame that, of a Medusa of ten pounds weight, what remains upon the filter through which its fluid parts, chiefly sea-water, have escaped, does not exceed two drachms. A great number of the *Medusæ* are phosphorescent, shining in the gloom of night like globes of fire; but the nature and the agents of this wonderful property remain to be discovered. Most of the *Medusæ* at certain seasons sting and inflame the hand that touches them; but the cause of this property is equally unknown.

MEE'RSCHAUM. (Germ. *foam of the sea.*) A silicated magnesian mineral found in various parts of Europe, but chiefly in some parts of Greece and Turkey. It is light and soft, and is employed in the Turkish dominions as fuller's earth. In Germany it is extensively used in the manufacture of tobacco pipes, which are prepared for sale by being soaked first in tallow, then in wax, and finally by being polished with shave grass. Imitation meerschaum pipes are sold in large quantities, and the greatest caution is necessary to guard against deception. To the connoisseur, the best criterion is the beautiful brown colour which the genuine meerschaum assumes after being smoked some time.

MEGALE'SIAN GAMES. (Gr. *μέγας, great.*) One of the most magnificent of the Roman exhibitions of the circus; in honour of Cybele, the mother of the gods.

MEGALI'CHTHYS. (Gr. μεγας, and *ιχθυς, a fish.*) An extinct genus of fishes, including species of great size; one of which, the *Megalichthys Hibberti*, has left its teeth and other parts in the channel coal of Fifeshire, and the Edinburgh coalfield.

MEGALO'NYX. (Gr. μεγας, and *ονυξ, a claw.*) A large fossil mammalian, the remains of which were found in a cavern in the limestone of Virginia in America.

MEGALO'PTERANS, *Megaloptera.* (Gr. μεγας, and *πτερον, a wing.*) A name given by Latreille to a family of Planipennate Neuropterous insects, comprehending those which have large wings horizontally folded.

MEGALOSAU'RUS. (Gr. μεγας, and *σαυρος, a lizard.*) The generic name applied by Dr. Buckland to an extinct genus of gigantic Saurians, discovered by him in the oolitic slate of Stonesfield, near Oxford. The species on which the genus is founded included individuals measuring from forty to fifty feet in length; they partook of the structure of the crocodile and monitor. The entire skeleton has not as yet been found. The femur and tibia measure nearly three feet each; and a metatarsal bone has been found of the length of thirteen inches. The bones of the extremities have large medullary cavities. The generic character is principally founded on the teeth, which Dr. Buckland thus graphically describes:—"In the structure of these teeth we find a combination of mechanical contrivances analogous to those which are adopted in the construction of the knife, the sabre, and the saw. When first protruded above the gum, the apex of each tooth presented a double cutting edge of serrated enamel. In this stage its position and line of action were nearly vertical, and its form like that of the two-edged point of a sabre, cutting equally on each side. As the tooth advanced in growth, it became curved backwards, in form of a pruning knife, and the edge of serrated enamel was continued downwards to the base of the inner and cutting side of the tooth; whilst on the outer side a similar edge descended but to a short distance from the point, and the convex portion of the tooth became blunt and thick, as the back of a knife is made thick for the purpose of producing strength. In a tooth thus formed for cutting along its concave edge, each movement of the jaw combined the power of the knife and saw; whilst the apex, in making the first incision, acted like the two-edged sabre. The backward curvature of the full-grown teeth enabled them to retain, like barbs, the prey which they had penetrated." (*Bridgewater Treatise*, i. p. 238.) These formidable teeth, which sufficiently bespeak the carnivorous and predatory nature of the extinct monster, were arranged in a pretty close series, in sockets, along the alveolar border of the jaws.

MEGANY'CTERANS. (Gr. μεγας, and *νυκτερις, a bat.*) The first division or tribe of the order *Cheiroptera*, including the largest species of bats, or "flying foxes;" which, however, are exclusively vegetable feeders, living mostly on soft fruits, and having the molar teeth adapted to that kind of food by their broad simple crowns. The tribe is also distinguished from the animal-feeding bats, whether bloodsuckers or insect catchers, by having the two innermost fingers armed with hook-shaped claws, and by the simple structure of the nose and ears. The alimentary canal, and especially the stomach of the great frugivorous bats, are likewise more complicated than in the other tribes. The meganycterans are distributed over the warmer parts of Asia, Africa, and the Polynesian Isles, but do not exist in America.

MEGA'RIAN SCHOOL OF GREEK PHILOSOPHY, founded at Megara by the disciples of Socrates, who retired thither after his death, and distinguished in later times by its logical subtlety. Its most celebrated names were those of Euclides, Eubulides, and Stilpo.

ME'GASCOPE (Gr. μεγας, and *σκοπεω, I view.*) An optical instrument proposed by M. Charles, of the French Academy of Sciences, for the examination of bodies of considerable dimensions. It is a modification of the solar microscope, and has been used for determining the curvature of the different parts of the eye. *See* Microscope.

ME'GASTOMES, *Megastoma.* (Gr. μεγας, and *στομα, mouth.*) The name of a family of Univalve shells, comprehending those which are not symmetrical, and which have a very large aperture or mouth.

MEGATHE'RIUM. (Gr. μεγας, and *θηριον, beast.*) The name given by Cuvier to a genus of extinct Edentate quadrupeds, including and represented by one of the most gigantic of terrestrial mammalia. The haunches of the *Megatherium Cuvieri* were more than five feet wide, and its body twelve feet long and eight feet high; its feet were a yard in length, and terminated by formidable compressed claws of immense size; its tail was of great length, and probably much larger than that of any other extinct or living terrestrial mammal. The head of the megatherium was relatively small: the cranium presents many of the peculiarities of that of the sloth. The upper jaw was armed with five teeth on each side, the lower jaw with four on each side: all the eighteen teeth belong to the molar series. They were perpetually growing, like the incisors of the Rodents; but had their grinding surface traversed by two transverse ridges, and their texture composed, as in the teeth of the sloth, of a central body of coarse ivory, a thick outer coating of cæmentum, and a thin intermediate layer of fine and dense ivory, which forms the prominent terminating ridges of the crown.

Nothing certain is known of the nature of the integuments of this singular and enormous animal; but the

fossil bony armour which has been conjectured to have appertained to the megatherium unquestionably belongs to another species of gigantic Edentate, more nearly allied to the armadillo. *See* GLYPTODON.

ME'GRIM. (Fr. migraine; probably from Gr. ἡμι, *half*, and κρανιον, *the skull.*) A violent intermitting pain affecting one side of the head.

MEI'ONITE. A mineral found in grains or small shining crystals, chiefly at Mount Somma, near Vesuvius. The name is from μειων, *less*; implying the *lowness* of the terminating pyramids of its crystals, and the consequent shortness of the axis of the primitive form.

MELÆ'NA. (Gr. μελας, *black.*) The black vomit. When blood is thrown up from the stomach it is generally black, in consequence of the presence of acid.

ME'LAM. A substance formed during the distillation of a mixture of sal-ammoniac and sulphocyanuret of potassium. It is said to consist of 12 equivalents of carbon, 11 of nitrogen, and 9 of hydrogen.

ME'LANCHOLY. (Gr. μελας, *black*, and χολη, *bile.*) A disease of the mind, chiefly characterized by ungrounded fear and apprehension of evil.

MELA'NIA. (Gr. μελας.) A genus of fluviatile Pectinibranchiate Gastropods, having a moderately thick shell, with an aperture longer than it is wide, enlarging opposite the spire, and the columella without folds or umbilicus: the length of the spire is various. They have long tentacula, with the eyes on their external side, and at about the third of their length from the base.

ME'LANITE. (Gr. μελας.) The black garnet.

MELANO'SIS. (Gr. μελας.) A malignant disease, characterized by deposition of a black matter in various parts of the body.

MELA'NTERITE. (Gr. μελας.) A mineralogical name of the native sulphate of iron.

MELANTHA'CEÆ. (Melanthium, one of the genera.) An order of Endogenous plants, with a regular six-parted inferior perianth, and six stamens with the anthers looking outwards. The number of species included in it is inconsiderable; but among them are the *Veratrum*, or white hellebore, and *Colchicum*, or meadow saffron, the poisonous qualities of which indicate the general properties of the order.

ME'LAS. (Gr. μελας.) A disease endemial in Arabia: it consists in the formation of dark brown or black spots upon the skin.

MELAS'MA. (Gr. μελας.) A disease of aged persons, in which a black spot appears upon the skin, which soon forms a foul ulcer.

ME'LASOMES, *Melasoma.* (Gr. μελας, and σωμα, *body.*) A tribe of Heteromerous Coleopterous insects, comprising those which are of a uniform black or grey colour.

MELASTOMA'CEÆ. (Melastoma, one of the genera.) A natural order of Exogenous plants, with polypetalous flowers and strongly ribbed leaves, inhabiting tropical countries in great numbers, but unknown in Europe in a wild state, and only occurring very sparingly in the temperate parts of America. In the equatorial regions of this continent they are extremely numerous; and some of the species bear berries, the juice of which stains the mouth black, whence their name (μελας, and στομα, *a mouth*). Their most characteristic mark is to have the anthers bent downwards and prolonged into a horn, which is held fast in sockets of the ovary before the flower expands. Many of the species are ornamental, none are useful.

MELCHI'SEDE'CIANS. In Ecclesiastical History, several sects of early heretics have been so termed, from the opinions entertained by them respecting the character and office of Melchisedec, arising from the language of St. Paul in the Epistle to the Hebrews. The Theodotians, in the 3d century, are said to have regarded him as superior to Christ. A sect of visionaries in Phrygia, who appear to have been a branch of the Manicheans, are reported to have made Melchisedec an object of adoration. Many divines of later times have entertained the belief that the Son of God appeared to Abraham under the form of Melchisedec. (Cuneus, *De Rep. Hebræorum.*)

ME'LCHITES. (Syr. malek, *king.*) In Ecclesiastical History, the Eutychians, when condemned by the council of Chalcedon, gave this name (royalists, imperialists) to the orthodox, who endeavoured to put the order of the Emperor Marcian into execution against them. Among Oriental Christians it now designates in a general manner all those who are neither Jacobites nor Nestorians, including the Maronites, Catholic Greeks, and non-Catholic Greeks, of the three Eastern patriarchates. (Mosheim, *Eccl. Hist.* vol. ii.)

MELEA'GRIS. (Gr. *a guinea-hen.*) A term employed by Linnæus to designate the genus of which the turkey is the type. The head and upper part of the neck is invested with a plumeless and carunculated skin: there is a cutaneous appendage of a similar construction under the throat, and another of a conical form on the forehead, which in the male, when under excitement, can be distended and elongated so as to hang over the point of the beak. From the lower part of the neck of the adult male hangs a tuft or tassel of stiff hairs. The coverts of the tail are shorter and stiffer than in the peacock, but can be erected and displayed in the same way. The tarsi of the male are armed with weak spurs. The common turkey (*Meleagris gallopavo*, L.) was introduced into Europe in the 16th century. Its size, and the excellence of its flesh, led to its being cultivated with peculiar care: it is now common, and widely dispersed. Its wild original of the American woods is of a greenish colour, with a copper gloss. A second, and much more beautiful species (*Meleagris ocellata*, Cuvier), has been discovered in Honduras: its domestication is greatly to be desired.

MELES. (Lat. meles, *a badger.*) A genus separated by Storr from the Linnæan *Ursus*, and characterized by Mr. Bell as follows: — Second incisor in the lower jaw placed behind the others; molars $\frac{5-5}{6-6}$, arranged in an uninterrupted series; feet plantigrade; a glandular pouch underneath the tail, having a transverse orifice. Since the extirpation of the common bear the badger, *Ursus meles* of Linnæus, which is a typical species of the present genus, is the sole representative of the Ursine family in our indigenous zoology. The habits of this quadruped are nocturnal, inoffensive, and slothful; its food consists of roots, earthnuts, fruits, the eggs of birds, insects, reptiles, and the smaller quadrupeds: its noxious qualities are consequently few and of slight moment, and by no means justify the exterminating war unremittingly waged against it. The muscular strength of the badger is great, its bite proverbially powerful; and a dog must be trained and encouraged to enter willingly into a combat with this species. The long claws of the fore feet enable the badger to dig with effect; and he habitually dwells in burrows, which he digs by choice in declivities covered by thick coppice, or concealed in the recesses of woods. The female prepares a nest of moss and grass, and brings forth her litter of three or four blind young in the summer season.

MELE'TIANS. In Ecclesiastical History, the partisans of Meletius, bishop of Lycopolis in Egypt, deposed in a synod at Alexandria about 306, on the charge of having sacrificed to idols during the persecution by Diocletian. He was supported by numerous adherents; and thus a schism began, which was partially concluded by the submission of Arsenius, chief of the party, to Athanasius in 333, but does not seem to have been wholly extinct for 150 years. (*Mosheim*, vol. i.)

MELICE'RIS. (Gr. μελι, *honey*, and κηρος, *wax.*) An encysted tumour, the contents of which resemble honey.

MELILO'TUS. (Lat mel, *honey*, and lotus, *a leguminous plant.*) A honey-scented plant, with an erect stem and long erect racemes of small yellow or white flowers, resembling those of clover, of which it was formerly regarded as a species. In some parts of Europe two or three species are cultivated as annual fodder-plants.

MELITŒ'A, or MELINŒA. (From Μελιταῖα, a state in Thessaly; or Μελιναῖα, a name of Venus, derived from μελι, *honey.*) In Zoology, a genus of beautiful corals, and also a genus of butterflies.

MELLI'PHAGANS, *Melliphagidæ.* (Gr. μελι, *honey*; φαγω, *I eat.*) A family of Tenuirosters, comprising the birds which feed on the nectar of flowers.

MELLITE, or MELILITE. (Gr. μελι, and λιθος, *a stone.*) A yellow crystallized mineral, composed of mellitic acid and alumine. It is very rare, and was first observed in the beds of brown coal in Thuringia. The term *melilite* has also been applied to a yellow mineral which occurs in very minute crystals in the fissures and cavities of lava. It fuses into a glass before the blowpipe, but its composition has not been determined.

MELLI'TIC ACID. The peculiar acid of the mellite or honeystone of Thuringia. According to Liebig the ultimate elements of this acid are 4 equivalents of carbon = 24, 4 of oxygen = 32, and 1 of hydrogen = 1.

ME'LLON. A lemon-yellow substance composed of 6 equivalents of carbon and 4 of nitrogen, obtained by heating dry bisulphuret of cyanogen.

MELOCA'CTUS. (Melon-cactus.) Round-stemmed, ribbed, succulent plants, covered with spines on the ridge of the ribs, and producing the flowers among wool, on a hairy head or cap, which is protruded from the top of the stem. They were included by Linnæus in his genus *Cactus*; and they are, in fact, scarcely distinguishable from those dismemberments of the genus to which the modern names of *Cereus* and *Echino cactus* are applied. For the sake of their grotesque form, they are often cultivated by persons curious in collecting singular vegetables.

MELODRA'MA. (Gr. μελος, *song*, and δραμα, *drama.*) A short drama in which music is introduced; but differing from the opera, as the greater part of the words are recited, and not sung. In Germany, the melodrama is a short dramatic piece in lyrical verse; but among ourselves, and in France, its character is chiefly that of being a vehicle for gorgeous decoration and scenery, with an insignificant plot, usually of a serious or romantic description.

ME'LODY. (Gr. μελῳδια; from μελος, *a song.*) In Music, the arrangement in succession of different sounds

for a single voice or instrument, being distinguished from harmony, which is the result of the union of two or more concording musical sounds.

ME'LOË. (Gr. μηλη, *a probe.*) A genus of Coleopterous insects, of the section *Heteromera*, tribe *Trachelides*, and family *Cantharidæ*, in the system of Latreille. In this genus the antennæ are composed of short and rounded joints, the intermediate of which are the largest, and sometimes so disposed that these organs present in this point, in several males, an emargination or crescent. The wings are wanting; and the elytra, oval or triangular, with a portion of the inner margin, crossing each other, only partially cover the abdomen, particularly in the females, in which this segment of the body is extremely voluminous. The meloës crawl along the ground, or upon low plants, on the leaves of which they feed. A yellowish or reddish oleaginous liquid exudes from the articulations of their legs. In some districts of Spain these insects are used in the place of the true blister-flies (*Cantharides*); they are also employed by the farriers. Latreille is of opinion that the modern meloës were the *Buprestes* of the ancients, — insects to which they attributed very noxious properties, supposing them to be fatal to the oxen that swallowed them.

MELOLON'THIDANS, *Melolonthidæ.* The family of Coleopterous insects, of which the May-chaffer (*Melolontha vulgaris*) is the type.

MELPO'MENE. (Gr. μελπομαι, *I sing.*) The muse who presides over tragedy; represented usually with a mask in one hand, a club or dagger in the other, and with buskins on her feet.

MELUSI'NE. In the mediæval Mythology of France, a beautiful nymph or fairy, whose history occupies a large space in the popular superstitions of that country. She is represented as the daughter of Helmas, king of Albania, and the fairy Persine; and as having married Raymund, count of Toulouse, who built her the magnificent castle of Lusignan (originally called Lusineem, the *anagram* of Melusine). Like most of the fairies of that period, she was doomed to a periodical metamorphosis, during which the lower part of her body assumed the form of a fish or a serpent. On these occasions she exerted all her ingenuity to escape observation; but having been once accidentally seen by her husband in this condition, she swooned away, and soon afterwards disappeared, none knew whither. But her form is said to be seen from time to time on the tower of Lusignan, clad in mourning, and uttering deep lamentations; and her appearance is universally believed to indicate an impending calamity to the royal family of France.

MELY'RIS. (Gr. μηλουρις, an insect mentioned by Nicander.) A Fabrician genus of Coleopterous insects, belonging to the section *Pentamera*, subsection *Serricornes*, tribe *Malacodermi*, and constituting the family *Melyridæ* in the system of Latreille; in which it is characterized as follows: — Palpi commonly short and filiform; mandibles emarginated at the point; body usually narrow and elongated; head covered at the base by a flat or slightly convex thorax; joint of the tarsi entire, and the terminal hooks unidentate or bordered with a membrane; antennæ usually serrate, and in the males of some species even pectinate.

MEMBRA'NA TYMPANI. The membrane which separates the internal from the external ear. The drum of the ear.

ME'MBRANE. The expansion of any of the tissues of the body into a thin layer. Anatomists generally enumerate three kinds of membrane; namely, the *mucous*, the *serous*, and the *fibrous*. The mucous membranes are those which line the canals of the body which are exposed to the action of air or foreign matters, — such as the lining of the nose, trachea, æsophagus, stomach, intestines, &c. The serous membranes form the lining of the sacs or closed cavities, as of the chest, abdomen, &c. The fibrous membranes are tough, inelastic, and of a tendinous character; such as the dura mater, the pericardium, the capsules of joints, &c.

ME'MNON. In Greek Mythology, a fabulous king of Ethiopia, son of the goddess Aurora, who is said to have assisted the Trojans in the siege of Troy, and to have been slain by Achilles. Several Egyptian kings of this name are also mentioned by different Greek writers. But the name is, in fact, supposed to be a general appellation or epithet (Mei-amun, *beloved of Ammon*) borrowed by the Greeks from the Egyptian language, and erroneously applied by them to particular individuals. The famous statue called by the Greeks Memnon, at Thebes in Upper Egypt, which possessed the real or imaginary property of emitting a sound like that of a harp, at the rising of the sun, is supposed to have been in the building called by M. Champollion the Rhamesseion, from its founder Rhameses, or Sesostris, of which the stupendous ruins are still seen between Medinet-Habou and Kournah. (See Champollion, *Lettres écrites d'Egypte et de Nubie*, p. 261.) The statue of black granite in the British Museum, already styled the brother of the younger Memnon, was found in the Rhamesseion. The real Memnonium was, however, probably the temple erected by Amenoph, or Amenothph. (Champollion, *ib.* p. 303.)

ME'MOIR. In Literature, two different species of composition are popularly designated by the terms Memoir and Memoirs. A short biographical notice of an individual, or a short essay on a particular subject (especially to accompany and explain a map, view, facsimile, or other representation of a curious object in art, &c.) is called a Memoir. This name is particularly appropriated to papers read before scientific or literary societies. The account, by an individual, of his own life, accompanied with narratives and remarks respecting the personages and events of the times in which he lived, is termed his Memoirs; being supposed, as the name denotes, to have been drawn up with the object of assisting his memory in reflecting on past events. In modern but incorrect diction the life of a person by another is also termed his Memoirs, if drawn up with a somewhat less regular arrangement, and containing more matter not immediately connected with the subject than the species of narration which we term a Life. The French were the earliest, and have always been by far the most successful writers, in this branch of literature. Their historical memoirs, partly autobiographical, and partly the works of authors who had access to the papers and memorials of those whose lives they illustrated, form a complete series from the 16th century to the present time, and throw the greatest light on some portions of history; while their memoirs of celebrated individuals in the ranks of literature and fashion are still more numerous and interesting. In the last century this branch of literature became so popular, that any distinguished individual who did not leave authentic memoirs of himself was sure to become the subject, after his death, of fabricated memoirs, published under his name; and this species of falsification, of which Voltaire then complained, appears to be now carried on as extensively as at any former period. The collections of historical memoirs recently edited in Paris contain three series of historical memoirs relating to French history, and one of English memoirs, translated, illustrating the period of our great civil war and revolution. The latter undertaking was conducted by M. Guizot.

MEMO'RIAL. In Diplomacy, a species of informal state paper much used in negotiation. Memorials are said to be of three classes. 1. Memorials in the form of letters, subscribed by the writer, and speaking in the second person as addressed to another. 2. Memorials proper, or written representations, subscribed by the writer, and with an address, but not speaking in the second person. 3. Notes, in which there is neither subscription nor address. Species of the first class of memorials are, circulars from the bureau of foreign affairs sent to foreign agents; answers to the memorials of ambassadors; and notes to foreign cabinets and ambassadors.

ME'MORY (Lat. memini, *I remember*), is defined to be the power or capacity of having what was once present to the senses or the understanding suggested again to the mind, accompanied by a distinct consciousness of past existence. The term is also employed, though more rarely, to denote the act or operation of remembering, or the peculiar state of the mind when it exercises this faculty, in contradistinction to the faculty itself. Various opinions have been propounded by metaphysicians respecting the nature and origin of the faculty of memory. Upon this point, however, it is not our intention to enter into any details, as this question is so mixed up with that of other faculties of the mind, such as perception and association, and such metaphysical questions, as personal identity, &c., as to be inseparable from them; and to these heads we must refer the reader for information. We may, however, remark, that the ancient Platonists and Peripatetics ascribed the faculty of memory to the common theory of ideas; that is, of images in the brain, or in the mind, of all the objects of thought; and in this opinion they were supported, with slight modifications, by many other philosophers of antiquity. But Dr. Reid, who has examined this question with great acuteness, has satisfactorily demonstrated the theory of the ancients to be very defective. The more modern theories of Locke, Hume, and other philosophers, also meet with little consideration from the same acute metaphysician, who, after exposing their fallacies, sums up in these words: — "Thus, when philosophers have piled one supposition on another, as the giants piled the mountains in order to scale the heavens, it is all to no purpose — memory remains unaccountable; and we know as little how we remember things past as how we are conscious of the present." (*Reid on the Human Mind*, p. 159. 185.)

MENA'CHANITE. Ferruginous oxide of titanium, found in the Vale of Menachan, in Cornwall.

MENDICANT FRIARS. *See* ORDERS, MENDICANT.

MENDI'CITY. (Lat. mendico, *I beg.*) The condition of habitual beggars. One of the greatest curses which can afflict a civilized society is the prevalence of mendicity; and it is very much to be regretted that the prejudices of excellent and humane persons have so constantly interposed, and still interpose, difficulties in the

way of the adoption and enforcement of correct principles on this subject. For there are too many who persist in seeing in mendicity only the natural expression of that indigence into which numbers are unhappily thrown by the inequality of property and uncertainty of employment prevailing in almost all communities; and who forget that the encouragement of it affords a premium to the idle, the artful, the criminal, — to all or any, in short, except those really deserving sufferers whom it is the object of true charity to relieve. (For the law of England, past and present, respecting mendicity, see VAGRANCY.) Under the operation of this law, of the national provision of the poor laws, and far more than either the activity of English industry, mendicity has long been less extensive and public in England than perhaps in any other country. And, owing to that very circumstance, it is perhaps worse in England than in any other country; that is, the established mendicants are more connected with the criminal part of the population. (See the recent report of the Constabulary Force Commission.) Ireland has long been unhappily celebrated for the prevalence of mendicity. The number of "destitute persons" in the island was estimated by Mr. Stanley in 1837 at about 80,000. (*Mr. Nicholl's Report on Poor Laws in Ireland*); the number of street mendicants in Dublin at nearly 1000, or almost *one twentieth* of the population. Mr. Lewis, following the evidence adduced before the Irish Poor Law Commission, divides the habitual mendicants into,—1. Wandering beggars, chiefly cripples, blind, maimed, &c. 2. Professional strolling beggars, who have no fixed domicile, and live constantly by mendicancy. 3. Town beggars, who live by mendicancy, but have a fixed domicile: these, he says, "are generally known by those who relieve them, and their character is not on the whole very bad." 4. Poor housekeepers, who are relieved by three or four neighbours, to whom their wants are known, but who would not resort to general begging. (*On Local Disturbances in Ireland*, 1835.) "Mendicancy and wretchedness," says Mr. Nicholl, "have become too common to be disgraceful." And he compares with truth the effects of indiscriminate alms-giving in Ireland to those of indiscriminate legal relief in England. What effect the new system of poor laws may have on this and other evils of that country, time must show. In France, *depôts de mendicité* were first founded in 1767; a kind of half way between prisons and hospitals for mendicants. Their situation was rendered dependent on their good behaviour. These receptacles held 6000 or 8000 persons in 1789. In 1808. by a new law, "vagabonds," mere vagrants, were distinguished from "beggars,"—*i.e.* disabled persons, or other persons begging within their own arrondissement: the former were sent to "maisons de détention." There are now two gaol depôts for Paris, at St. Denis and Villers Coterets. In 1838 the prefet of police reported that they had manifestly diminished mendicity at Paris. (Dégerando, *De la Bienfaisance Publique*, iii. part 3. b. 1.) "The road to mendicity," says M. Sismondi, "is now too wide and too easy; instead of calling on religion to smooth it, we should multiply as far as possible the resources of the poor, in order to prevent their being dragged into it." *See* POOR LAWS.

ME'NILITE. A mineral somewhat resembling semi-opal, found at Menil Montant, near Paris.

MENI'SCUS. A lens convex on one side and concave on the other. *See* LENS.

MENISPE'RMIC ACID. An acid contained in the berries of the *Menispermum cocculus* (*Cocculus indicus*), where it exists in combination with the vegetable alkali called *pierotoxia*.

MEN'NONITES. The title by which the Anabaptists of Holland came to be distinguished, after they had put themselves under the guidance of Menno, a native of Friesland, who undertook to moderate the extraordinary fanaticism of those sectarians. (*Mosheim*, transl., ed. 1790, v. 490.) *See* BAPTISTS, ANABAPTISTS.

MENOBRA'NCHUS. (Gr. μενω, *I remain*, βραγχια, *gills*.) A Perennibranchiate amphibian, which retains the external gills.

ME'NOPOME, *Menopoma*. (Gr. μενω, and πωμα, *a lid*.) A Perennibranchiate amphibian, which retains the opercular aperture, but not the external gills.

ME'NORHA'GIA. (Gr. μην, *a month*, and ῥεω, *I flow*.) Flooding; immoderate menstrual discharge; hæmorrhage from the uterus.

ME'NSTRUUM (Lat. mensis, *a month*), signified, in the language of the old chemists, some preparation or drug which could only operate effectually at a particular period of the moon or month; but it is now used for any fluid substance which dissolves a solid body.

MENSURA'TION. Though this term literally signifies the act of measuring, it is usually employed to denote the branch of practical geometry which teaches the methods of calculating the dimensions and areas of figures, the volumes of solids, &c., from the measurement of certain lines or angles of the figures or solids, which supply the requisite data.

Every rectilineal plane figure may be decomposed into triangles; and hence the mensuration of such figures resolves itself into the determination of the sides or area of a triangle. (*See* TRIGONOMETRY.) Solids bounded by planes may in like manner be resolved into pyramids, and their contents consequently determined by the methods of elementary geometry. (*See* PYRAMID.) The determination of the lengths of curve lines, the areas of figures bounded by curves, and of solids bounded by curve surfaces, requires the application of the integral calculus. (*See* QUADRATURE, RECTIFICATION.) For the areas and volumes of the most usual geometrical figures, see the respective terms, as CIRCLE, ELLIPSE, &c.

ME'NTUM. (Lat. *the chin*.) In Mammalogy, the term is restricted to the anterior and inferior margin of the mandible, or lower jaw. The *mentum prominulum* is that which extends beyond the perpendicular line dropped from the upper margin of the lower jaw; the *mentum absconditum* is that which cannot be distinguished.

MENU, INSTITUTES OF. The name given to the most celebrated code of Indian civil and religious law; so called from Menu, Menou, or Manu, the son of Brama, by whom it is supposed to have been revealed. The Hindoos themselves ascribe to this system the highest antiquity; and many of the most learned Europeans are of opinion that of all known works there is none which carries with it more convincing proofs of high antiquity and perfect integrity. Sir W. Jones assigns the date of its origin somewhere between Homer and the Twelve Tables of the Romans; and Schlegel asserts it as his belief that it was seen by Alexander the Great in a state not materially different from that in which we possess it. The Institutes of Menu are of a most comprehensive nature: they embrace all that relates to human life; the history of the creation of the world and man; the nature of God and spirits; and a complete system of morals, government, and religion. The work, says Sir W. Jones, contains abundance of curious matter, interesting both to speculative lawyers and antiquaries, with many beauties which need not to be pointed out, and with many blemishes which cannot be justified or palliated: it is a system of despotism and priestcraft; both, indeed, limited by law, but artfully conspiring to give mutual support. But, notwithstanding these and other defects, as has frequently been remarked, the most striking features by which the code of Menu is distinguished are the rigour and purity of its morals. Many of its maxims have all the sublimity of the precepts of Christianity; to which, in fact, they bear a close resemblance, not only in the style of thought but of expression. Thus, "Let not a man complain, even though in pain; let him not injure another in deed or in thought; let him not even utter a word by which his fellow-creatures may suffer uneasiness." Again, "Let him bear a reproachful speech with patience; let him speak reproachfully to no man; with an angry man let him not in return be angry; abused, let him answer mildly." The inspired words of the Psalmist, "The fool hath said in his heart there is no God," are thus almost verbally rendered, "The wicked have said in their hearts no one sees us: yes, the gods distinctly see them, and so does the spirit within their breasts." The Institutes of Menu have been translated into the English and French languages: into the former by Sir W. Jones in 1794, the latter by Des Longchamps in 1830 (Strasburg). An edition of the original Sanscrit, together with Sir W. Jones's translation, was published at Calcutta in 1822-25 by Sir Graves Haughton.

MENU'RA. (Gr. μενος, *strength*, and ουρα, *a tail*.) A name invented by Dr. Shaw for a genus of birds peculiar to Australia, the true affinities of which have been the subject of much discussion and diversity of opinion among ornithologists. Cuvier observes that the *Mænuræ*, or lyre-pheasants, evidently belong to the order *Passerinæ*, and approach the thrushes in their beak, which is triangular at the base, elongated, slightly compressed, and emarginate at the point. Only one species is at present known, and this is chiefly peculiar for an extraordinary sexual development of the tail feathers of the male. Of these there are three kinds: the twelve common ones, with very fine and widely separated barbs; two more in the middle, of which only one side is furnished with thickly-set barbs; and two external ones, curved in the figure of an *S*, or like the arms of a lyre, whose internal barbs, large and thickly set, form a kind of broad riband, while the external ones are very short, becoming longer only near the tip. The female has only the twelve ordinary quills.

MENYA'NTHES. (Gr. μηνος, and ανθος, *flower*.) A genus of Gentianaceous plants with powerful tonic properties. The *M. trifoliata*, a wild aquatic plant, with white flowers densely crested with hairs, is employed in medicine as a bitter, emetic, tonic, and diaphoretic.

MENY'NGES. (Gr. μηνιγξ, *a membrane*.) The membranes which cover the brain are so called.

MEPHI'TIS. (Lat.) Any noxious exhalation; but more particularly applied to carbonic acid gas. Mephitis was the name of a Latin goddess who was invoked by the Romans as their protectress against noxious vapours.

MERCA'PTAN. A liquid composed of sulphur, car-

bon, and hydrogen, which has received the above name from its energetic action on mercury — *corpus mercurium captans*. (Zeise, *Annales de Chimie et Physique*, lv. 87.)

MERCA'TOR'S CHART, or PROJECTION. A representation of the sphere on a plane, in which the meridians are represented by equidistant parallel straight lines, and the parallels of latitude also by straight lines perpendicular to the meridians. This projection, which is universally adopted for nautical charts, by reason of the facilities which it affords in navigation from the circumstance that the rhumb, or sailing course between two points, is represented by a straight line, was invented by Gerard Mercator (his true name was *Kauffman*, of which Mercator is the Latin equivalent), a native of Rupelmonde, in East Flanders, born in the year 1512. But, though Mercator gave his name to the projection, it does not appear that he knew the law according to which the distance of the parallels from the equator increases. The true principles of the construction were found by Edward Wright, of Caius College, Cambridge, who explained them in his treatise, entitled *The Correction of certain Errors in Navigation*, published in 1599, and are as follows:—Suppose one of the meridians on the globe to be divided into minutes of a degree; one of these, taken at any parallel of latitude, will be to a minute of longitude, taken on that parallel, as the radius of the equator to the radius of the parallel; that is, as radius to the cosine of the latitude, or as the secant of the latitude to radius. This proportion holds true on the map in this sense, that if a minute of the equator be taken as the unit of a scale, and that unit be considered as the radius of the tables, then the representation of a minute of latitude will be expressed by the number in the trigonometrical tables which is the secant of that latitude. Hence, in the map, while the degrees of longitude are all equal, the degrees of latitude marked on the meridian form a scale of which the distances go on increasing from the equator towards the poles, each being (approximately) the sum of the secants of all the minutes of latitude in the degree. The numbers resulting from the addition of the secants of the successive minutes reckoned from the equator form a scale of meridional parts, which is given in all books of navigation. The very remarkable property of this projection, namely, that the divisions of the meridian are analogous to the excesses of the logarithmic tangents of half the respective latitudes augmented by 45°, above the logarithm of the radius, was discovered by Bond about the year 1645; but was first demonstrated by James Gregory, in his *Exercitationes Mathematicæ*, published in 1668. (See the *Scriptores Logarithmici*, vols. ii. and iv.)

MERCURIA'LE. The first Wednesday after the great vacation of the parliaments, under the old French régime. On that day they met to discuss grievances and deficiencies, and to reprimand members for misconduct. Hence, an harangue of reproof is popularly termed in French a *mercuriale*.

ME'RCURY. (Probably from the Lat. merx, *merchandise*.) The Latin name of the Grecian Hermes. He was the son of Jupiter and Maia, and discharged the office of the messenger of the gods. Part of his duty was also to conduct the shades of the dead to the infernal regions. He presides over eloquence, profit, good fortune, and theft; in which he was himself so great a proficient that, on the day of his birth, he stole fifty kine from the herds of Apollo, whom he repaid by the gift of his invention, the lyre. (See the Hymn ascribed to Homer, with the beautiful translation of it by Shelley.) His attributes, exploits, and insignia are briefly enumerated by Horace (Ode I. 10.):—

> Mercuri facunde, nepos Atlantis,
> Qui feros cultos hominum recentum
> Voce formasti catus, et decoræ
> More palæstræ,
> Te canam, magni Jovis et Deorum
> Nuntium curvæque lyræ parentem
> Calidum, quicquid placuit jocoso
> Condere furto.

Between which passage and the lines of Ovid (*Fasti*, v. 663—669.) a curious coincidence will be found. Mercury was represented as a youth lightly clad, with the *petasus*, or winged hat, and wings at his heels. In his hand he bears the emblem of his herald's office, the *caduceus*, a rod with two serpents twined about it. The more ancient statues of Mercury were square blocks of stone, with a rudely carved head on them. They were set up in great numbers in the streets of Athens.

ME'RCURY. In the Solar System, the planet nearest the sun. The mean distance of Mercury from the sun is 0·3870981, the radius of the earth's orbit being taken as unit; it is consequently little more than a third of the earth's distance, and equal to about 36,000,000 of miles. His mean sidereal revolution is performed in 87·969258 mean solar days, and his successive oppositions or conjunctions take place at intervals of 115·877 mean solar days. The orbit is inclined to the ecliptic in an angle of 7° 0′ 9″; and its eccentricity is greater than that of any other of the old planets, being 0·205515, the major axis being unit. Mercury being an inferior planet always appears in the neighbourhood of the sun; his greatest elongation, or angular distance from the sun, amounts only to 28° 48′; so that he is very seldom visible to the naked eye. His apparent diameter varies from 5″ at his superior conjunction when at his greatest distance from the earth, to 12″ at his inferior conjunction when nearest the earth. At a distance equal to the mean distance of the sun from the earth, the apparent diameter is 6·9″. His true diameter, compared with that of the earth taken as unity, is ·398, or about 3140 miles. On account of the smallness of the planet and its proximity to the sun, it is difficult to distinguish any variety on the surface. The disk is round, and, in a good telescope, exhibits phases; and the planet is supposed to revolve about its axis in the space of 24 h. 5 m. 28 sec. Mercury is sometimes seen to pass over the sun's disk. This can only happen when he is in one of his nodes nearly at the same time that he is at his inferior conjunction. The phenomena are of more frequent occurrence than the transits of Venus, but of far less astronomical importance. The five next transits will be visible in this country, and will occur at the following dates:—1845, May 8.; 1848, Nov. 9.; 1861, Nov. 11.; 1868, Nov. 4.; 1878, May 6. *See* PLANET.

ME'RCURY. This metal is found chiefly in the state of *sulphuret*, which is decomposed by distillation with iron or lime. It is also found *native*. Mercury is the only metal which is liquid at common temperatures; it is white and very brilliant. It freezes and assumes a crystalline texture at 40° below zero. Its specific gravity is 13·5. It boils at 660°, and its vapour condenses upon cool surfaces in minute brilliant globules. It is not altered by exposure to air at common temperatures, but when kept in vessels to which air has access, at a temperature near its boiling point, it gradually becomes converted into a deep red crystalline substance, which is the *peroxide*, or *red oxide*, *of mercury*. When mercury is dissolved in cold dilute nitric acid, the pure alkalis throw it down in the form of *black protoxide*. The same oxide is also obtained by triturating calomel with solution of caustic potash. These are the only definite oxides of mercury. The equivalent of this metal is about 200, and the oxides, consisting respectively of 1 atom of mercury and 1 of oxygen, and 1 and 2, are represented by 200 + 8 = 208, and 200 + 16 = 216. Mercury is represented in chemical formulæ by *hg.*, from the Latin *hydrargyrum*, literally signifying *water silver*. The symbol of the protoxide will then be (*hg.* + *o.*), and of the peroxide (*hg.* + 2 *o.*). Each of these oxides combines with the acids, and produces the *protosalts* and *persalts* of mercury.

Mercury and Chlorine.—There are two *chlorides of mercury*; a *protochloride* or *calomel*, and a *perchloride* or *corrosive sublimate*. Calomel may be obtained by mixing 60 parts (1 equivalent) of common salt, or chloride of sodium, with 248 parts (1 equivalent) of protosulphate of mercury, and exposing the mixture in a proper subliming vessel to a red heat; the chlorine of the salt combines with the mercury of the sulphate to form protochloride of mercury (consisting of 200 mercury and 36 chlorine); and the sodium of the salt uniting with the oxygen of the oxide of mercury becomes soda, which, with the sulphuric acid, forms sulphate of soda. Calomel may also be obtained by mixing 200 parts of mercury with 272 of corrosive sublimate, and subliming the mixture. When thoroughly washed and levigated, calomel is a tasteless white powder; its specific gravity is 7·2. When heated it acquires a yellow colour; and at a temperature below redness it rises in dense white fumes, which are deposited in the form of a white powder upon cold surfaces. It is insoluble in water. When hastily sublimed it often becomes a crystalline horny mass, and occasionally forms beautiful prismatic crystals. It is sometimes found native; forming, however, a very rare ore, called, from its appearance, *horn quicksilver*.

Perchloride of mercury, or corrosive sublimate, is obtained by sublimation from a mixture of 120 parts of common salt (or 2 equivalents), and 296 (or 1 equivalent) of persulphate of mercury. It rises in the form of a white crystalline substance, of an acrid metallic taste, highly poisonous, soluble in 20 parts of cold and in 2 of boiling water. Its specific gravity is 5·2. When heated it evaporates in acrid fumes, at a temperature below that required for the volatilization of calomel. Corrosive sublimate is a compound of 1 equivalent of mercury and 2 of chlorine. In the above process for preparing it the chlorine is furnished by the chloride of sodium, and sulphate of soda is the other product.

Bisulphuret of Mercury, known also by the name of cinnabar or vermilion, is prepared artificially by heating together 100 parts of mercury with about 20 of sulphur; they form a black compound, which, when strongly heated, rises in the form of a deep crimson-coloured sublimate; this, reduced by long trituration into a fine powder, acquires a brilliant red colour. It is tasteless, and insoluble in water; it consists of 200 mercury and 32 sulphur, or (*hg.* + 2 *s.*) A black *protosulphuret of mercury* (*hg.* + *s.*) is precipitated by sulphuretted hydrogen from a solution of the protonitrate. When a mixture of equal weights of

finely-powdered peroxide of mercury and Prussian blue is boiled in water till the blue colour disappears, the solution yields, when filtered and evaporated, a crop of straw-coloured prismatic crystals, which are *bicyanuret of mercury* : 2 *cy*. + *hg*.

Mercury is found in various parts of the world. Among the principal mines are those of Almaden, near Cordova, in Spain; Idria, in Carnolia; Wolfstein and Morsfield, in the Palatinate; Guancavelica, in Peru. It is stated by Dr. A. T. Thomson, in his *Dispensatory*, that most of the mercury used in this country is brought from Germany. But, whatever may have been the case formerly, this is not certainly true at present. On the contrary, of 314,286 lbs. of quicksilver imported in 1831, none was brought from Germany; 269,558 lbs. were brought direct from Spain, and 13,714 lbs. from Gibraltar; of the latter a part was derived from Carniola, and a part from Spain; 31,014 lbs. were brought from Italy. Only 192,310 lbs. were retained for home consumption in 1831. (*Parl. Paper*, No. 550. Sess. 1833.) Quicksilver is produced in several of the provinces of China. During the war, when the intercourse between Europe and America was interrupted, the price of quicksilver rose to such a height in the latter that it answered to import it from China; but since the peace it has been regularly exported to the latter. At an average of the 14 years ending with 1828, the imports of quicksilver by the English and Americans into Canton amounted to 648,085 lbs. a year, worth 340,262 dollars. (*Lords' Report of* 1831, p. 657.) Besides its uses in medicine, mercury is extensively employed in the amalgamation of the noble metals, in water-gilding, the making of vermilion, the silvering of looking-glasses, the making of barometers and thermometers, &c.

ME'RGER, in Law, is the destruction of a lesser estate in lands and tenements by the acquisition of a greater estate in the same immediately succeeding by the same party and in the same right. Thus an estate for years is said to merge, or sink, in an estate for life, if there be no other estate vested in another person intervening between the two; and an estate for life in an estate of inheritance. There is no merger of an estate tail.

ME'RGUS. (Lat. mergus, the name of a sea-bird, supposed to apply to the cormorant.) A Linnæan genus of Anserine birds, characterized by a beak thinner and more cylindrical than that of the ducks, and with each mandible armed at its margins with small pointed teeth directed backwards, like those of a saw; the upper mandible is curved downwards at its extremity. The goosander (*Mergus serrator*) and the merganser (*Mergus merganser*) are examples of this genus.

MERI'DIAN. (Lat. meridies, *mid-day*.) In Astronomy, a great circle of the sphere passing through the earth's axis and the zenith of the spectator. It is the circle on which the latitudes of places are reckoned, commencing from the equator, which it intersects at right angles. The terrestrial meridian is the great circle (or rather ellipse) formed by the intersection of the surface of the earth with the plane passing through the poles and the place of the spectator. *See* DEGREE.

MERI'DIAN ALTITUDE. The altitude, or height above the horizon, &c. in degrees, of any celestial object, when it crosses the meridian of a place.

MERI'DIAN, FIRST. The meridian from which longitudes are reckoned. The choice of the first meridian is entirely arbitrary; and most nations reckon the longitudes from their capital, or meridian passing through their principal observatories. Thus, in English works, the longitude is reckoned from Greenwich; in French, from Paris; in Russian, from St. Petersburg, &c. Ptolemy employed the Canary Islands, the French formerly reckoned from Ferro, and the Dutch from the Peak of Teneriffe. Mercator chose the island Del Corvo. *See* LONGITUDE.

MERIDIAN LINE. A line traced on the surface of the earth, coinciding with the intersection of the meridian of the place with the sensible horizon.

MERIDIAN OF A GLOBE, OR THE BRASS MERIDIAN, is a graduated circular ring, within which the globe is suspended and revolves, and by means of which it is connected with the frame bearing the horizontal scale. Meridian lines are also traced on the globe itself, usually at 15° distance, or a difference of longitude corresponding to an hour of time. It is probable that these, with the parallels of latitude, suggested to Descartes the idea of *co-ordinates*, which he applied so successfully to connect algebra with geometry.

MERI'NO SHEEP. A breed of sheep till lately peculiar to Spain, but now reared in Saxony, England, and more particularly in Australia, chiefly for the superior fineness of their wool. The word *merino* signifies an overseer of pasture lands, and is applied to this breed of sheep, because, in Spain, they are kept in immense flocks, under a system of shepherds, with a chief as a head, and with a general right of pasturage all over the kingdom. The best flocks of Spanish merinos are found in Leon and Castille: of the Saxon variety, at Stolpen and Rochsburg; but merinos are to be found in North America, the Cape of Good Hope, and above all in New South Wales, which promises to be one of the principal woolgrowing countries in the world. *See* SHEEP.

ME'RLON. In Fortification, the part of the parapet or epaulement included between two embrasures.

ME'RMAID. (Germ. meer, *sea*, and magd, *maid*.) A fabulous creature; the fore part woman, the hinder half fish. The species of actually existing animals that, viewed at a distance in the sea, may have originated the idea of mermen and mermaids, are the cetaceous *dugong* and *manatee*: these have their fore fins rudely fashioned like arms and hands, and terminate behind in a fish-like tail. The nipples are pectoral; and they are often seen ascending to the surface to breathe, clasping their suckling young to the breast.

MERO'PIDANS, *Meropidæ*. The family of Insessorial birds of which the bee-eater (*Merops*) is the type.

ME'ROS. (Gr.) In Architecture, the plane face between the channels in the triglyphs of the Doric order.

MERU'LIDANS, *Merulidæ*. The family of Dentirostral perchers, of which the thrush (*Merula*) is the type.

MESE'MBRYA'NTHEMUM (Gr. μεσος, *the middle*, βρυω, *I grow*, and ανθος, *a flower*), is a very large genus of succulent Cape plants, of which many species are conspicuous for the beauty of their flowers, which expand in sunshine, and close up in gloomy weather. They are chiefly interesting on account of the hygrometical quality of their fruit, which when wetted opens out into numerous radiating valves, and when dry contracts with force into a compact and apparently solid body. This fruit is sometimes called the fig-marigold.

ME'SENTERY. (Gr. μεσος, and εντερον, *an intestine*.) The membrane by which the intestines are attached to the vertebræ; it is formed of a duplicature of the peritonæum, and supports the nerves and vessels of the intestines.

ME'SMERISM. *See* MAGNETISM, ANIMAL.

MESNE PROCESS. Such process as intervenes between the beginning and end of a suit. It is opposed to final process, or that which takes place by way of execution after judgment. Imprisonment for debt on mesne process was effected by the bare affidavit of one person, stating that another owes him 20*l*. It is abolished, under certain exceptions, by 1 & 2 Vict. c. 110. *See* ARREST.

MESOCO'LON. (Gr. μεσος, and κωλον, *the colon*.) The mesentery of the colon: it is an extensive duplicature of the peritonæum.

ME'SOLABE. (Gr. μεσος, and λαμβανω, *I take*.) An instrument employed by the ancients for finding two mean proportionals between two given lines, which were required in the problem of the duplication of the cube. (See *Eutocius on the Works of Archimedes*, and the 3d Book of *Pappus*.)

ME'SOLYTE. (Gr. μεσος, and λιθος, *a stone*.) A hydrated silicate of alumina, lime, and soda. It is also called *needle-stone*.

MESOPHY'LLUM (Gr. μεσος, and φυλλον, *a leaf*), is the parenchymatous tissue forming the fleshy part of a leaf between the upper and lower integuments.

MESOTHO'RAX (Gr. μεσος, and θωραξ, *the chest*), in Entomology, is the posterior segment of the alitrunk, which bears the posterior pair of wings and the third or posterior pair of legs.

ME'SOTYPE. (Gr. μεσος, and τυπος, *form*.) A hydrated silicate of alumina and soda. It has also been called natrolite. It occurs in trap rocks and in the ancient lava of Vesuvius.

MESS, in Military Language, signifies the public dinner prepared either for the officers of the same regiment, or for those of different regiments, if in garrison, and to the support of which they are bound to contribute a portion of their pay. Generally speaking, only married officers are exempted from contributing to, and dining at, the mess; the rest preside over it in rotation, without respect to military rank.

ME'SSENGER. In Naval Language, a hawser or small cable of about sixty fathoms in length, wound round the capstan, and having its two ends lashed together. When the anchor is to be weighed this rope is attached to the cable by the *nippers*, and thus acts as an endless rope. Chain messengers are sometimes employed.

ME'SSENGERS, KING'S. Certain officers employed in the secretary of state's department to convey despatches, either at home or abroad. They were formerly employed in serving the secretaries' warrants for the apprehension of parties charged with high treason, or other grave offences; and in such cases it was not unusual for them to detain their prisoners at their own houses. In the year 1713 the ambassador of the emperor of Morocco was taken into custody by a king's messenger, and released only after a lapse of six months.

MESSI'AD. The name given to the only modern epic poem of Germany; the subject of which is, as the name implies, the sufferings and triumph of the Messiah. It is written in hexameter verse, for which, as we have elsewhere observed, the German is better fitted than any modern language, and consists of 20 books. The publication of this poem procured for its author unbounded

reputation; but posterity does not appear to sanction the high award pronounced on it by contemporaneous writers. Schlegel, indeed, maintains that the modern literature of Germany may be said to date from the *Messiad;* but this high praise must be understood as referring chiefly to its having been among the first productions in which the power and resources of the German language were developed, rather than to its innate merits as an epic poem, or to the influence it has exercised over the national poetry of Germany. The reputation of Klopstock among his own countrymen rests chiefly on his Odes; and it must be admitted that in all those parts of his epic poem into which a lyric spirit could be infused,—in other words, whenever the feelings or the sympathies were to be excited,—there are few poets, either ancient or modern, to whom he deserves to be postponed; but, on the other hand, the dignity and sublimity of his sentiments are not unfrequently disfigured by the pedantry and affectation of his style, and the tediousness of his episodes.

MESSI'AH. An old Hebrew word, signifying the anointed or sacred, corresponding with the Greek word *χριστος;* and in this sense applied to the Saviour, as it was anciently applied by the Jews to their prophets, priests, and kings, it being customary to anoint all these high personages when they assumed their office. We read in Psalm ii. 2., "The kings of the earth set themselves against the Lord and against his *anointed*" (*i. e.* his Messiah); and in Psalm xlv. 7., "Therefore God, even thy God, hath *anointed* thee with the oil of gladness above thy fellows." This *anointing*, therefore, was not a sensible unction with external oil or ointment, but a symbol of it; a spiritual, an internal unction of grace, given by the Holy Ghost—"And God gave not the spirit by measure unto him." St. Luke tells us that our Saviour applied this *anointing* to himself at the time when he entered the synagogue of Nazareth. In the synagogue service there is a pause for any one to speak or read who can enlighten or instruct the people: when this period came our Saviour stept forward, took up the Hebrew roll, and opened it at the book of the prophet Isaiah, and read aloud this passage:—"The spirit of the Lord is upon me, because he hath *anointed* me to preach the gospel to the poor," &c.; and he closed the book, and he gave it to the minister, and sat down. The eyes of all them that were in the synagogue were fastened on him; and he said, "This day is this scripture fulfilled in your ears; and all bare him witness, and wondered at the gracious words which proceeded out of his mouth." (Luke, iv. 17. &c.)

ME'SSUAGE (modern Lat. messuagium), in Law, is said to be properly a dwelling-house with a small portion of land adjacent, or the site of the manor. It is now one of the general words used in the legal description of dwelling-houses with the land attached.

MESTI'NO. In Spanish America, the child of a Spaniard or creole and a native Indian. *See* MULATTO.

METABO'LIANS. (Gr. *μεταβολη, change.*) A subclass of insects, including all those which undergo a metamorphosis.

METACA'RPAL. (Gr. *μετα, between,* and *καρπος,* in the sense of *the wrist.*) Belonging to the metacarpus, or that part of the hand which is between the wrist and fingers.

METACE'NTRE. (Gr. *μετα,* and *κεντρον, centre.*) A term first applied by Bouguer to that point of a floating body in which, when the body is disturbed from the position of equilibrium, the vertical line passing through the centre of buoyancy meets the line which when the body is at rest passes through the centre of buoyancy and centre of gravity. In order that the body may float with stability, the position of the metacentre must be above that of the centre of gravity. *See* HYDROSTATICS.

METAGA'LLIC ACID. When gallic acid is rapidly heated up to about 480°, carbonic acid and water are evolved, and a black product remains soluble in the alkalies, and forming insoluble compounds with many of the metallic oxides. This product has been termed *metagallic acid;* its ultimate elements are 12 atoms of carbon = 72, 3 atoms of oxygen = 24, and 3 atoms of hydrogen = 3, making its equivalent = 99.

METALLOI'DS. (Gr. *μεταλλον, a metal,* and *ειδος, form.*) A term sometimes applied by chemists to the inflammable non-metallic bodies, such as sulphur, phosphorus, &c. The metallic bases of the fixed alkalies and alkaline earths have also been by some called metalloids, in consequence probably of their low specific gravity.

ME'TALLURGY. (Gr. *μεταλλον,* and *εργον, a work.*) The art of separating metals from their ores. The principal metallurgic processes are described under the respective metals.

ME'TALS (Gr. *μεταλλον*), are distinguished by their very peculiar lustre, arising out of their opacity and reflective power in regard to light. They conduct electricity and heat; and they have not been resolved into other forms of matter, so that they are regarded as simple or elementary substances. When their compounds are electrolysed the metals appear at the negative surface, and are hence considered as electro-positive bodies. They are enumerated in the following table, together with the names of the chemists by whom they were discovered, the date of the discovery, their specific gravities, melting points, equivalent or atomic weights, and symbolic abbreviations. For their individual distinctive characters see the respective metals. Lantanum is omitted, inasmuch as its properties and combining weight have not been accurately examined.

METAMECO'NIC ACID, is produced by boiling the aqueous solution of meconic acid. It evolves carbonic acid, and becomes brown. Two atoms of meconic acid are thus resolved into 1 of metameconic acid and 2

* Smith's forge.

† Oxyhydrogen blowpipe.

of carbonic acid. It is represented by 12 *car.* + 4 *h.* + 10 *ox.*

METAMO'RPHOSIS. (Gr. μετα, indicating *change*, and μορφη, *form*.) Transformation. The heroic poem of Ovid, in which he recounts the most celebrated mythological narratives respecting the gods of Greece and Rome, and the changes of this description effected by their supernatural power, is called the *Books of Metamorphoses*.

METAMO'RPHOSIS. In Entomology, the change of form which the Metabolian insects and some other animals undergo in passing from one stage of existence to another; in each of which they manifest different habits, and have a different organization. The three stages of a Lepidopterous insect are *larva*, *pupa*, and *imago*.

ME'TAPHOR. (Gr. μεταφερω, *I transfer*: indicating the substitution of one word for another of similar meaning.) In Rhetoric, a figure by which a word is transferred from the subject to which it properly belongs, and applied to another which has some similitude to its proper subject, with a view to give energy to the expression of the former. A comparison or simile (*see* COMPARISON) appears to be only a metaphor with the addition of a sign denoting that it has been thus transferred. Thus "the silver moon" is a metaphorical expression; the "moon, bright as silver," a comparison. As language advances from the mere indication of sensible objects by names to the expression of the feelings and wants of a complicated mode of life, it becomes more and more metaphysical in character, until it is found that a very large proportion of the words in common use are either metaphors, or are words derived from foreign languages, and whose primary sense as derivatives is the same with their secondary or metaphorical sense in the language from which they came. Thus, the English word "character," used a few lines above, is drawn from the metaphysical use of the Greek χαρακτηρ, which in its primary signification denoted something engraven on a hard substance. Metaphors have been divided, by writers on rhetoric, into several classes; but the most appropriate are those which are termed analogical, and which derive their force, not from any actual resemblance between two objects, but from a resemblance between the relations which they bear respectively to certain other objects. Thus "the sea of life" is a common and appropriate metaphor; not from any resemblance between the idea of the visible sea and the complex notion of that abstraction which we term human life, but because there is a fancied similarity between the position of navigators in an uncertain voyage and that of human beings engaged in the manifold scenes of life.

ME'TAPHOSPHO'RIC ACID. A term by which some chemists designate the dry flaky acid obtained by burning phosphorus under a bell glass of air or oxygen.

METAPHY'SICS. (Gr. μετα, *after*, and φυσις, *nature*.) A word employed, in popular usage, to denote all those inquiries which are conversant about objects other than merely physical and sensible. It is an observation of Sir James Mackintosh, that "the term *metaphysics* affords a specimen of all the faults which the name of a science can combine. To those who know only their own language it must, at their entrance on the study, convey no meaning. It points their attention to nothing. If they examine the language in which its parts are significant, they will be misled into the pernicious error of believing that it seeks something more than the interpretation of nature. It is only by examining the history of ancient philosophy that the probable origin of this name will be found, in the application of it as the running title of several essays of Aristotle, which were placed in a collection of the manuscripts of that great philosopher *after* his treatise on physics." The censure thus conveyed we cannot, with all deference for so eminent an authority, regard as more than partially correct. Though the account of the origin of the word is, as far as it goes, the true one, it does not comprehend the whole truth.

If Sir James Mackintosh had examined the contents of those treatises of Aristotle to which he adverts, he would have found that the title *metaphysics* was prefixed to them, not, as his words imply, merely because they happened, according to the arrangement of the compiler, to follow the physical treatise; but *also* because there was the best possible reason for their being so placed, in the fact that the inquiries which compose them were conceived by Aristotle himself to admit of a general distinction from that department of inquiry which he included under the name of physics. The first few chapters of the τα μετα τα φυσικα are devoted to the elucidation of this very distinction, and to the endeavour to clear up the popular confusions on the subject, by marking at once the objects of the highest philosophy, and the faculty whereby they were to be apprehended. Admitting, therefore, as we most readily do, that great misapprehensions are popularly entertained with regard to the nature of metaphysics, we shall endeavour, as far as the limits of the present article will permit us, to remove such mistakes, by distinguishing the science of metaphysics from other sciences, with which, as they are closely connected with it, it has too frequently been confounded.

Metaphysics we understand to be the science which regards the ultimate grounds of being, as distinguished from its phenomenal modifications. As a means of attaining this end, it considers the correlative of being, knowledge; and knowledge, not merely in reference to its *form*, as it is capable of law and regulation, for that is the province of logic — nor in regard to its history, and the successive stages of its development, which are the objects of psychology, or mental philosophy — but knowledge as it is in relation to being, or objective reality. Philosophers have not been satisfied with marking the resemblances of the appearances in nature, and the order in which they succeed each other, whether those appearances were outward and sensible, or internal and revived by observation of their own mental processes; they have not even been content with the discovery that their knowledge of phenomena was self-consistent, and obeyed certain determined or determinable canons or forms; they have felt that the highest end of science could then only be attained when all knowledge was perceived to depend on a one ultimate principle, which should demonstrate at once its consistency with itself and its absolute foundation in reality. That the science of this ultimate unity is that to which the greatest philosophers have with more or less distinctness assigned the name of metaphysics, we may safely appeal to the history of philosophy for a sufficient demonstration.

Whether the object thus proposed were one which the human faculties are capable of reaching is itself the first problem of metaphysics, and enters not, therefore, into that with which we have at present to do,—a definition of the word. We may, indeed, with Hume and his followers, reject all such attempts as chimerical, and endeavour to resolve the speculations to which they have led into the delusions of association or caprice; or we may, with Kant, confine ourselves to the *critique* of our mental laws, and, as the result of our investigation, pronounce that we possess no faculty capable of reaching outward reality. In the first case, if we have been careful to ascertain that our analysis has at every step been legitimate, we are bound to admit, not that metaphysics is an impossible science, but that it does not yet exist *as* a science. In the second instance, we are constrained to allow that all reality is subjective only; and that we can only know things in relation to our own modes of knowing; and this is itself a metaphysical principle, preclusive of further inquiry. In defiance, however, alike of the sneers of the sceptic, and the yet profounder scepticism of the critical philosophy, our own days have witnessed the rise, in Germany and France, of more than one professed system of metaphysical science. The frequency of such endeavours as these, undertaken, as they are, by men of such acknowledged acuteness and philosophical insight as Fichte, Schelling, and Hegel, even if they inspire us with no hope of a nearer approximation to the objects which they pursue, may at least serve to convince us that the propensity to such speculations constitutes an inalienable and indestructible instinct of our intellectual and moral nature.

ME'TAPLASM. (Gr. prep. μετα, signifying *change*, and πλασσω, *I form*.) In Grammar, a general term, comprehending all those figures of diction which consist in alterations of the letters or syllables of a word; taking place in three ways,— by augmentation, diminution, or immutation. 1. Augmentation at the beginning, *prosthesis;* in the middle, *epenthesis;* at the end, *paragoge;* to which may be added *diæresis*, adding to the number of syllables by the resolution of a diphthong. 2. Diminution at the beginning, *aphæresis;* in the middle, *syncope;* at the end, *apocope;* by contraction of two vowels, *synæresis* or *crasis*. 3. Immutation, *antithesis*, signifying the change of one letter for another; *metathesis*, transposition of the order of letters. (See those respective heads.)

META'STASIS. (Gr. μετα, and στασις, *station*.) The transference or translation of a disease from one part of the body to another.

METATA'RSUS. (Gr. μετα, and ταρσος, *heel*.) The instep is so called by surgical writers.

META'THESIS. (Gr. μετα, and θεσις, *position*.) In Grammar, the transposition of the letters of a word; a figure of uncommon occurrence in modern orthography, but which very ordinarily takes place in the gradual formation of the dialects of a language: *e.g.* German, ross; English, horse. *See* METAPLASM.

ME'TATOME. (Gr. μετα, and τεμνω, *I cut*.) In Architecture, the space between one dentil and the next.

META'YER. (Fr.; in Italian, mezzaiuolo; Lat. colonus medietarius.) In France and Italy, a farmer holding land on condition of yielding half the produce to the proprietor, from whom he receives tools and stock. Land thus occupied is said to be held in *métairie*. The conditions of the contract, however, vary essentially in different countries and districts. The antiquity of this mode of letting land is very great: it is probably the same which was called by the Romans *locatio in partibus* (see

Plin. Epist.); and the farmer thus holding was also termed *colonus partiarius*. It now prevails extensively in the south and middle of France, throughout Italy, in parts of Spain, and, it is said, in the East. For a very valuable summary of the character and effects of this agricultural system, the reader may be referred to Mr. Jones's *Essay on Wealth*; and for a highly-coloured view of the state of the peasantry under it in some parts of Italy, to *M. Sismondi's Etudes sur l'Economie Politique*.

METE'MPSYCHO'SIS. (Gr. μετα, *change*, and ψυχη, *soul*.) A Greek word denoting the migrations of the soul through different successive bodies. The doctrine of the transmigration of souls has existed in the belief of various religious and philosophical sects from the remotest antiquity. It formed the leading doctrine of one of the most celebrated schools of philosophy in the whole heathen world (*see* PYTHAGOREAN PHILOSOPHY); it was said too to have found numerous adherents in Egypt; but it is chiefly among the Indians that this doctrine has taken deep and permanent root. With them it appears to have been an article of faith from the period at which we can first perceive any trace of their existence as a nation; and it is not going too far to say that not only all the opinions, but even all the manners of the Indians, are at this hour built upon this doctrine. The Indian doctrine of *metempsychosis* rests on the supposition that all beings derive their origin from God, and are placed in this world in an altogether degraded condition, from which they all, but more particularly the human race, must either decline into still lower degradation, or rise gradually to a higher state more accordant with their divine original, according as they give ear to the vicious or the virtuous suggestions of their nature. It must be remarked, however, that the Indians make a wide distinction between the future destiny of those who have passed through life tainted by the usual vices and infirmities of human nature, and those whose lives have been spent in the constant discharge of religious duties. In the latter case, the soul does not pass through different stages of existence; "but proceeds directly to reunion with the Supreme Being, with which it is identified, as a river at its confluence with the sea merges therein altogether. His vital faculties, and the elements of which his body consists, are absorbed completely and absolutely; both name and form cease; and he becomes immortal, without parts or members." (See Mr. Colebrooke's translation of Extracts from the *Brahma-Sutras*, in the *Transac. of the Roy. As. Soc.*, vol. ix.)

METEMPTO'SIS. *See* PROEMPTOSIS.

METEORO'LOGY. (Gr. μετεωρος, *aërial*, and λογος, *discourse*.) The science of meteors, or the science which explains the various phenomena which have their origin in the atmosphere. Under the term meteorology, it is now usual to include, not merely the observation of the accidental phenomena to which the name of meteor is applied, but every terrestrial as well as atmospherical phenomenon, whether accidental or permanent, depending on the action of heat, light, electricity, and magnetism. In this extended signification, meteorology comprehends climatology, and the greater part of physical geography; and its object is to determine the diversified and incessantly changing influences of the four great agents of nature now named, on land, in the sea, and in the atmosphere. *See* ATMOSPHERE, CLIMATE, and the various terms referred to under METEORS.

ME'TEORS. (Gr. μετεωρα.) A name given to any phenomena of a transitory nature which have their origin in the atmosphere. Meteors are of various kinds. Some are produced simply by a disturbance of the equilibrium of the atmospheric fluid, and are called *aërial meteors*. (*See* WINDS, WHIRLWINDS.) A second class arise from the deposition of the aqueous particles which the atmosphere holds in solution, and which are precipitated in consequence of a diminution of pressure or temperature, sometimes in a fluid and sometimes in a concrete form. These are called *aqueous meteors*. (*See* DEW, FOGS, HAIL, RAIN, SNOW, VAPOUR, &c.) A third class of meteors, or atmospherical phenomena, are caused by the action of the aqueous particles dispersed in the atmosphere on the rays of light. These are called *luminous meteors*. (*See* FATA MORGANA, HALO, MIRAGE, PARHELIA, RAINBOW.) A fourth class are the *igneous meteors*, comprehending those which present the phenomena distinctive of combustion. *See* AEROLITE, AURORA BOREALIS, FIRE BALLS, LIGHTNING, SHOOTING STARS, &c.

METHE'GLIN. (Germ. meth, *mead*.) A beverage made of honey and water, fermented by the addition of yeast.

ME'THOD. From the Greek word μέθοδος, which signifies a journey undertaken in quest of any object, or a way of attaining any end: hence, in Logic, it denotes a mode of investigating truth. Thus we have the dialectic method, the inductive method, the analytical method, &c. *See* DIALECTICS, INDUCTION, ANALYSIS.

ME'THODISTS. The body of Christians to whom this name is chiefly applied are the followers of the late John Wesley, the founder of this numerous sect; hence called Wesleyan Methodists. But the term bears a more extensive meaning, being applied also to several bodies or sections of Christians who have seceded or withdrawn from the Wesleyan denomination.

The origin of the Methodist society took place at Oxford in 1729. After the Revolution, when the principles of religious toleration were recognized amidst the progress of free inquiry, the clergy of the established church were thought by some to have sunk into a state of comparative lukewarmness and indifference. This alleged degeneracy was observed with pain by John Wesley and his brother Charles, when students at the University of Oxford; and being joined by a few of their fellow-students who were intended for the ministry in the established church, they formed the most rigid and severe rules for the regulation of their time and studies, for reading the scriptures, for self-examination, and other religious exercises. The ardent piety and rigid observance of system in every thing connected with the new opinions displayed by the Wesleys and their adherents, as well as in their college studies, which they never neglected, attracted the notice and excited the jeers of the various members of the university, and gained for them the appellation of *Methodists*; in allusion to the *methodici*, a class of physicians at Rome who practised only by theory. (Celsus, *in Prefat. de Medicina*.)

In the mean time Wesley took orders in the established church, and acted for a few months as assistant to his father, who was rector of Epworth, in Lincolnshire. After the death of the latter he was induced (1735), in company with his brother Charles and two other friends, to accept of an offer to go to Georgia in North America, to preach the gospel to the Indians. On his return to England in 1737, Wesley officiated in several churches of the establishment. But the higher ranks were offended at his declamatory and enthusiastic mode of preaching; and the clergy having disclaimed some of his doctrines, the churches in general were soon shut against him. It was his desire, however, to be allowed to officiate in the pulpit of his native church. His object, in truth, was to effect a reformation in the church, not to recede from connection with it; and the rules he observed himself, and imposed upon his followers, were designed as supplementary to the established ritual, not as superseding it. But the circumstances to which we have referred threw his labours into a different, and ultimately an opposite channel; and in short, without having at first intended it, he became the founder of the most numerous class of Dissenters in Great Britain.

Being thus virtually expelled from the established church, he preached in Dissenting chapels in London and other places where he could obtain admission. In course of time, and owing to the vast multitudes that crowded to listen to his ministrations, he adopted the expedient of officiating in the open air, and commenced field-preacher. He first formed his followers into a separate society in 1738, the year after his return from America, though he referred the establishment of Methodism to a prior date. (See *Wesley's Eccles. Hist.* vol. iv. p. 175.) Wesley, from this date, devoted his time and his great talents exclusively to the propagation of what he regarded the doctrines of the gospel, and to the extension of that sect of which he was the founder. His labours were chiefly confined to England; but he also paid visits to Scotland and Ireland,—in the former of which his success was inconsiderable. (*Sir H. Moncreiff's Life of Dr. Erskine*, cap. vii.) But while he confined his own labours to Great Britain and Ireland, he was not inattentive to the spiritual necessities of other countries, and, by means of a succession of missionaries, propagated his doctrines to a very great extent in America and many of the West India islands.

The unparalleled success which attended his great missionary exertions was not gained without much obloquy and persecution, particularly in the United Kingdom. Owing to the intelligence and liberality of the age, neither himself nor any of his missionaries were exposed to stripes and imprisonment; but all of them met with violent opposition on the part not merely of clergymen, both established and dissenting, and the wealthier classes, but also of the people; and some of them were beset with mobs, assailed by showers of stones and other missiles, and sometimes dragged through the streets as raving enthusiasts and as disturbers of the public peace. It must, at the same time, be confessed that the imprudence of some of his followers contributed somewhat to the reproach which they experienced.

Finding his societies rapidly increasing, and having been refused assistance from the established clergy, Wesley was induced to have recourse to lay preachers; an expedient which he was at first exceedingly averse to adopt, but which he afterwards found most efficient in promoting the triumph of his views. He was thus enabled to exercise superintendence over all his followers, and greatly to extend his sphere of action.

Though Wesley objected to his adherents being called Dissenters, and required them to attend the established church when they had no opportunity of hearing their own preachers, yet his creed is professed Arminianism,

and differs, therefore, in many points from what is generally understood to be the doctrine of the Thirty-nine Articles. He denied the doctrine of election; though he admitted that *certain* persons and churches have been elected, and that *great* events have been foreordained. He differed from the system of Calvin in regard to the extent of the atonement, which he maintained was for all men. He held that repentance preceded faith. He taught that, by virtue of the blood of Christ, and the operation of the Holy Spirit, it was the privilege of Christians to arrive at that maturity in grace and participation of the divine nature which excludes sin from the heart, and fills it with perfect love to God and men. (*Wesley's Plain Acc. of Christian Perfection.*) These and other minor opinions in which he differed, or seemed to differ, from the creed of the established church, are still retained by the Methodists. (In addition to Wesley's works, particularly his *Sermons*, see *Benson's Apology for the Methodists;* and *Myles's Chronol. Hist. of the Methodists.*) Wesley and his followers, we may here observe, continued long after their separation from the church to read the service of that church; nay the practice was continued, in a few instances, after his death. The great body of the Wesleyans, though they are now classed among Dissenters, are in favour of a national establishment of religion, and give the benefit of their support to the established church of England. There is, in truth, a pretty large body who fluctuate between Methodism and the national creed.

But while this is the case, the Methodists have adopted a system of church discipline and government quite distinct from those of the establishment, and which seems to partake as much of presbytery as of any other polity. Of this system, which is considerably complicated, the following are the leading features: — 1. Each society or congregation is divided into smaller bodies, called *classes*, each class embracing from twelve to twenty persons, one of whom is styled the *leader*. Each society has also a body of men called *stewards*, whose office is similar to that of deacon in the established church. The duties of leaders — namely, visiting the sick and holding religious intercourse with the members belonging to their class — are, in many respects, akin to those of lay-elders in the Presbyterian Church of Scotland. The leaders, stewards, and minister meet once a week (and this is called a *leaders' meeting*), on the religious business of the society; and to account for the funds received from the members in support of schools or of the gospel.

A number of these societies united constitutes a *circuit*, which is large or small as the circumstances of each locality require. One of the ministers within the district is termed the *superintendent*. The ministers officiating in the circuit meet all the classes quarterly, and speak personally to each member. Those whose conduct is devoid of reproach receive a ticket, the chief use of which is to prevent imposture. After the conference with the classes another meeting (called a *quarterly meeting*) is held, consisting of all the ministers, leaders, and stewards in the circuit. On this occasion the stewards deliver their collections to a *circuit steward;* and every thing relating to secular matters is publicly settled. At this meeting, also, the candidates for the ministry are proposed; and the stewards, after a definite period of service, are changed.

From five to ten or fifteen of the circuits, according to their extent, form a *district*, the ministers in which meet annually; the meeting being termed a *district meeting*. This assembly has authority "to try and suspend ministers who are found immoral, erroneous in doctrine, or deficient in ability; to decide concerning the building of chapels; to examine the demands from the circuits respecting the support of clergymen; and to elect a representative to attend and form a committee, four days before the meeting of the annual conference, in order to prepare a draught of the stations for the ensuing year. (*Myles, ut suprà.*) The circuit stewards are present at this meeting during the settlement of all financial matters. The judgment of the assembly is conclusive until the meeting of the conference, to which an appeal is allowed in all cases.

The *conference*, which is the supreme judicatory, and whose decisions are final, consists, strictly speaking, only of a hundred of the senior itinerant preachers, in terms of a deed of declaration executed by Wesley and enrolled in chancery. In this deed the meeting is termed "the Conference of the people called Methodists." But the conference is generally composed of the preachers elected at the previous district meetings to be their representatives, of the superintendents of the circuits, and of every minister who chooses to attend; all of them being allowed the same right of voting as the hundred, or legal conference. From this body all authority emanates; and by them all regulations to be observed throughout the whole Methodist connection are framed. In their name are levied all the funds required for carrying on the operations of the body. Ministers are by them appointed to the stations they are respectively to occupy; they nominate the superintendents of the various districts; they decide on all cases of appeal; and, generally speaking, the whole state of the connection comes under their review and controul. All their deliberations are carried on with closed doors, so that the people have no check over their proceedings; but the results of their discussions are annually published after each meeting, under the title of *Minutes of Conference*, which embody the laws of the society. The gradation of courts, and the supreme authority being vested in the conference, are somewhat similar in spirit and operation to the various judicatories of the Church of Scotland, in which, like the conference of the Methodists, the general assembly is supreme; the chief exception being that the latter judicatory is composed of certain relative proportions of lay elders and clergymen, while the Methodist conference is confined exclusively to ministers. (*General Rules of the Methodist Society; Adam's Religious World*, vol. iii. pp. 113—119.)

At the death of Wesley, in 1791, there were, in Great Britain and Ireland, about 300 itinerant preachers in connection with the new sect, and 1000 of what are called local preachers, — some of them, however, having very small congregations, — and 80,000 members. But the Wesleyan Methodists have established foreign stations in Australia, Van Diemen's Land, Gibraltar, Malta, Germany, &c.; and so rapidly have they increased that the number of Wesleyan Methodists in 1840, both at home and abroad, amounted to 1,137,424; and the total number of preachers, regular and supernumerary, was 5031.

Various offshoots have taken place from the Wesleyan Methodists at various times: among the most important of which may be reckoned the followers of Whitfield, formerly the coadjutor, and afterwards the most powerful and eloquent opponent of Wesley, and supporter of Calvinism; the Methodists of Lady Huntingdon's connection, in whose chapels service is performed according to the ritual of the church of England; the Welsh Calvinistic Methodists; the Primitive Methodists, or Ranters (which see); the New Connection Methodists (which see); the Independent Methodists; Bryanites, Warrenites, &c. Some of these sects, particularly the Whitfieldians, are nearly allied in church government and discipline to the Independents; and it is not unlikely that a coalition may take place between them and this latter denomination. (In addition to the works already quoted, see *Journal of John Wesley; Lives of Wesley*, by Coke, Moore, &c., but particularly that by Southey; *Nightingale's Portraiture of Methodism; Mosheim's Church History*, vol. vi. pp. 281—288.)

ME'THYLENE. (Gr. *μεθυ*, *wine*, and *υλη*, *wood.*) When wood is subjected to destructive distillation, there is formed along with the tar, acetic acid, and other products, a highly volatile and inflammable liquid, which, when purified by distillation off quicklime, was called spirit or alcohol of wood, or pyroxilic spirit. The hydrocarbon, which forms the basis of this form of alcohol, and to which the term *methylene* has been applied, is presumed to consist of 1 atom of carbon = 6, and 1 atom of hydrogen = 1: its density (in reference to hydrogen) being just half that of olifiant gas, or = 7. The alcohol of wood is a *hydrate* of this hydrocarbon; or a compound of 1 atom of methylene = 7, and 1 atom of water = 9: the equivalent, therefore, of the alcohol of wood is $7 + 9 = 16$.

ME'TOCHE. (Probably from *μετεχω*, *I partition.*) In Architecture, the space between two dentils.

METŒ'CI. (Gr. *μέτοικοι*, *sojourners.*) The resident aliens, who formed a large class of the inhabitants of Athens. They were distinguished from the few full citizens by many disabilities and burdens. They had no share in the administration of the state, and were precluded from the power of possessing landed estates. Each was compelled to purchase the shelter he received from the state by the payment of a small annual sum (*μετόικιον*), and to place himself under the guardianship of a citizen (*προστάτης*), who was his formal representative in the courts of law. They were generally engaged in mercantile and mechanical business.

METO'NIC CYCLE. So called from Meton, its inventor (B. C. 432.). A cycle of nineteen years, or, more accurately, of 6940 days; at the end of which time the new moons fall on the same days of the year, and the eclipses return in nearly the same order. The reason of this is, that in 19 solar years there are 235 lunations (with a difference of a few hours), and very nearly one complete revolution of the moon's nodes. The cycle was corrected by Calippus. *See* CALIPPIC PERIOD, CYCLE.

METO'NYMY. (Gr. *μετωνυμία;* derived from the preposition *μετα*, *change*, and *ὄνομα*, *a name.*) In Rhetoric and Composition, a figure by which the name of an idea or thing is substituted for that of another, to which it has a certain relation. Thus, the effect is frequently substituted for the cause — "grey hairs" stands for "old age:" the abstract for the concrete — "What doth gravity" (*i.e.* the grave person) "out of his bed at midnight?" — substance for quality, precedent for subsequent, &c.

The term *Metonomasia* (of the same origin as metonomy) was invented during last century by the French to designate a practice which prevailed to a great extent among the literati of the Continent; viz. of adopting some name in preference to their own.

METO'PA. (Gr. μετα, *between*, and οπη, *a hole*.) In Architecture, the square space in the frieze between the triglyphs of the Doric order. It is left either plain or decorated, according to the taste of the architect. In the most ancient examples of this order, the metopa was left quite open, as is manifest from a passage alluded to in the art. ARCHITECTURE.

METOPO'SCOPY. (Gr. μέτωπον, *a forehead*, and σκοπεω, *I view*.) The art of divination by inspecting the forehead, treated of especially by the famous Cardanus. The signs of the forehead are chiefly its lines; but moles and spots are also supposed to have their particular meaning. The lines are under the dominion of their several planets.

ME'TRE. (Gr. μετρον, *measure*.) In the classical sense of the word, a subdivision of a verse. The Greeks measured some species of verses (the dactylic, choriambic, antispastic, Ionic, &c.) by considering each foot as a metre; in others (the iambic, trochaic, and anapæstic) each *dipodia*, or two feet, formed a metre. Thus, the dactylic hexameter (the heroic verse) contains six dactyls and spondees: the iambic, anapæstic, and trochaic *trimeter*, six of those feet respectively. A line is said to be *acatalectic* when the last syllable of the last foot is wanting; *brachycatalectic*, when two syllables are cut off in the same way; *hypercataleptic*, when there is one superfluous syllable.

ME'TRONOME. (Gr. μετρον, and νομος, *a law*.) An instrument for measuring musical time. It is contrived on the principle of a clock having a short pendulum, whose bob being moveable up and down on the rod, is thus capable of increasing or decreasing the length of a note or bar as required by the character of the music. The length or duration of a note is often expressed at the head of a piece of music by stating that a pendulum of a given length in inches will vibrate a minim, crotchet, or other note, as the case may be.

METRO'POLIS. (Gr. μητηρ, *mother*, and πολις, *city*, or *state*.) 1. A parent state from which colonies have sprung, in which sense the word is uniformly employed by ancient Greek writers. 2. The chief city of a province in the later ages of the Roman empire. The Christian church having adopted the secular division of the Roman empire into provinces, the episcopal seat established in every such city, and the bishop of it himself, were termed metropolitan. 3. In modern usage, the chief or capital city of an independent state.

METROPO'LITAN, in early Ecclesiastical History, was a title applied to the archbishop, or chief ecclesiastical dignitary, resident in a city. The establishment of metropolitans took place at the end of the third century, and was confirmed by the council of Nice. In some of the Protestant states of Germany the title exists to the present time, and the person in possession of it has rank equivalent to the bishops of the English church.

ME'ZZANINE. (Lat. mezzano, *middle*.) In Architecture, a story of small height introduced between two higher ones.

ME'ZZO SOPRA'NO. (Ital.) In Music, a high counter-tenor, having the *C sol ut* clef on the second line.

MEZZOTI'NTO. (Ital. *half tinted*.) A particular method of engraving on copper. *See* ENGRAVING.

MIA'SMA. (Gr. μιαινω, *I infect*.) Infectious or contagious matter. The term is generally applied, under the name of *marsh miasma* (malaria of the Italians), to the infectious emanations from marshy lands and stagnant waters, which are peculiarly characterized by producing various forms of intermittent and remittent fevers.

MI'CA. (Lat. mico, *I shine*.) A mineral generally found in thin *elastic* laminæ, soft, smooth, and of various colours and degrees of transparency. Silica, alumina, potash, and oxide of iron are its principal components. It is one of the constituents of granite. In some parts of Siberia and elsewhere it forms an article of trade, often known under the name of *Muscovy glass*.

MI'CA SLATE. One of the lowest of the stratified rocks, composed of quartz and mica. *See* GEOLOGY.

MI'CHAELMAS. The feast of St. Michael the Archangel. It falls on the 29th of September, and is supposed to have been established towards the close of the fifth century; Brady says in 487. In England, Michaelmas is one of the regular periods for settling rents; and an old custom is still in use of having a roast goose to dinner on that day, probably because geese are at that period most plentiful, and in the highest perfection. (See *Brand's Pop. Antiq*.)

MI'CHAEL, SAINT. A French order of knighthood, instituted by Louis XI. in 1469, in honour of St. Michael, the supposed ancient protector of France. The motto of this order was "Immensi tremor oceani." It was at first and for some time after its institution in high repute; but under Catherine of Medicis, who lavished it indiscriminately, it came to be held of no account, from which state it never recovered.

MI'CROCOSM. (Gr. μικρος κοσμος, *little universe*.) Man has been called so by some fanciful writers on natural philosophy and metaphysics, by reason of a supposed correspondence between the different parts and qualities of his nature and those of the universe.

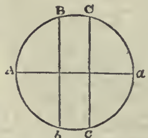
MICRODA'CTYLUS. (Gr. μικρος, and δακτυλος, *a digit*.) A name proposed by M. Geoffroy for the short-toed genus of wading birds called by Illiger *Dicholophus*. See that word.

MI'CRODON. (Gr. μικρος, and οδους, *a tooth*.) The name of a genus of extinct fishes, belonging to the thick-toothed or Pycnodont family, in the Ichthyological system of Agassiz.

MICRO'METER. (Gr. μικρος, and μετρον, *measure*.) An instrument applied to telescopes and microscopes for measuring very small distances, or the diameters of objects which subtend very small angles. A great number of contrivances of various kinds, and depending on different principles, have been employed for this purpose; but it will be sufficient to give a general description of some of the most useful or remarkable ones.

Wire Micrometer.—This instrument, when placed in the tube of a telescope, at the focus of the object glass, presents the appearance represented in the annexed figure (fig. 1.). A *a* is a spider's web line, or very fine wire fixed to the diaphragm; and B *b* and C *c* are similar wires stretched across two forks, each connected with a milled-headed screw. By means of these screws the two wires, B *b* and C *c*, which are exactly parallel to each other, are moveable in the direction perpendicular to A *a*; and, in order that the wire A *a* may be placed in any direction relatively to the meridian, there is an adjusting screw, which works into an interior toothed wheel, and turns the apparatus round in its own plane perpendicular to the axis of the telescope.

(1.)



The method of using the micrometer is as follows:—Suppose the object to be accomplished were the measurement of the *angle of position* and distance of two very close stars; the telescope being set and kept on the objects, the micrometer is turned by its adjusting screw until the spider line A *a* coincides with the line joining the two stars, or *threads* them both at the same moment. The milled heads of the screws, which carry the two moveable wires, are then turned until B *b* bisects one of the two stars, and C *c* bisects the other. The observation is now completed, and it only remains to ascertain the position and distance indicated by the micrometer. For the first of these purposes, the circumference of the micrometer is divided into degrees and minutes, and read by two verniers: this reading gives the position of A *a* in respect of the horizontal and vertical planes, and consequently the angle of position of the two stars. To find their distance, the head of the screw which carries one of the moveable wires, for instance C *c*, is turned until C *c* coincides with B *b*; and the number of revolutions, and parts of a revolution, required to effect the coincidence, gives the distance of the stars when the value of the *scale* of the micrometer is known; that is to say, when the number of seconds of space which correspond to one revolution of the screw is known. The screws must be made with great accuracy, and their heads are usually divided into 60 equal parts, representing seconds.

The value of the scale, or of a revolution of the screw, is obtained in the following manner:—Set the two wires, B *b* and C *c*, apart to a certain number of revolutions, and place them in the direction of the meridian. Observe the transits of several stars of known declination over the wires; then multiply each interval of seconds by 15, and by the cosine of the star's declination; and, taking the mean, you have the seconds of space which correspond to a known number of revolutions of the screw. (See Appendix, by the Rev. R. Sheepshanks, to *Professor De Morgan's Explanation of the Gnomonic Projection of the Sphere*.)

Circular Micrometer.—This instrument, which differs entirely from the above, was first suggested by Boscovich, in the *Leipzic Acts* for 1740, and used by Lacaille in observing a comet in 1742; but seems afterwards to have fallen into disuse, until it was revived by Dr. Olbers, about 1798. The principle may be explained as follows: If the field of a telescope be perfectly circular (which may be effected by means of a diaphragm turned in a lathe), and if its diameter be determined from observation, the paths of two celestial bodies across the field may be considered as two parallel chords, which are given in terms of a circle of known diameter. The differences of the times at which two stars arrive at the middle of their paths will be their ascensional differences; and the distance between the chords, which is readily computed

from their lengths, gives the difference of the declinations of the two bodies.

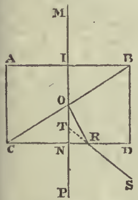
The most approved construction of the annular micrometer is that of the late Fraunhofer. It consists of a disc of parallel plate glass (fig. 2.), having in its centre a round hole of about half an inch in diameter, to the edges of which a ring of steel is cemented, and afterwards truly turned in a lathe. The disc being mounted in a brass tube, so that it may be accurately adjusted in the focus of the eye-piece, and applied to a telescope, the steel ring is alone visible, and appears as if suspended in the atmosphere, whence the instrument is called the *suspended annular micrometer*. The advantage of this construction consists in the accuracy with which the moment of ingress or egress is determined, from the body being seen in the field of view before it comes up to the edge of the steel ring. The annular micrometer is conveniently used for comparing the place of a small star or a comet with that of a known star in nearly the same parallel of declination. (*Astronomische Nachrichten*, b. iv.)

(2.)

Divided Object Glass, or Double Image Micrometer.— This instrument is formed by dividing the object glass of a telescope or microscope into two halves, the straight edges being ground smooth, so that they may easily slide by one another. A double image of an object in the field of view is produced by the separation of the segments; and, by bringing the opposite edges of the two images into contact, a measure of the diameter of the object is obtained in terms of the extent of the separation. From its being used to measure the diameter of the sun, this is usually called the *heliometer* (*see* HELIOMETER). Instead of a divided object glass, Ramsden preferred a divided lens in the eye-tube, which form of the instrument is called the *dioptric micrometer*. The double image micrometer was suggested by Roemer, about 1678; but first brought into use by Bouguer, about 1748.

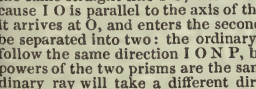
Micrometer by Double Refraction.— The Abbé Rochon conceived the ingenious idea of applying the principle of double refraction to micrometrical measurement. Conceive two prisms, A B C and B C D (fig. 3.), formed of the same crystal, and so disposed that the face A B of the first is perpendicular to the axis of the crystal, while, in the second, the axis is parallel to the line of the intersection of the two faces C B and C D, so that the axes of crystallization of the two prisms are at right angles to each other. The prisms are placed in perfect contact, and cemented by mastic; and together form a plate of which the opposite sides are parallel. Now, suppose a ray of light M I to fall perpendicularly on the face A B; it will proceed through the prism A C B, in the same straight line I O, without being separated, because I O is parallel to the axis of the crystal. But when it arrives at O, and enters the second prism B C D, it will be separated into two: the ordinary ray will continue to follow the same direction I O N P, because the refracting powers of the two prisms are the same; but the extraordinary ray will take a different direction O R (towards B D, if the crystal is attractive, as rock crystal; but towards A C, if the crystal is repulsive, as Iceland spar), and, on emerging from the prism at R, will be refracted in the line R S. The angle P T S of the inclination of the two rays after their emergence from the prism is constant for the same crystal, and must be determined by experiment.

(3.)



Let us now conceive this apparatus to be placed in the tube of a telescope, of which O (fig. 4.) is the object glass and F the focus, and the telescope directed upon a distant object at D (as a planet), the diameter of which, $m\ n$, is to be measured. Suppose the double prism at T′: two images will be formed; the ordinary image at a, and the extraordinary image at b'. By sliding the prisms along the tube towards O the distance between the images will be increased; and by sliding them towards the focus F, it will be diminished; and if placed exactly in the focus, the two images will coincide. Let V denote the visual angle or apparent magnitude of the object, f the focal distance F O of the telescope, U the constant angle a T b depending on the prism, and D the distance F T: we shall then have the diameter of the image $= f$ tan. V, and the distance $a\,b =$ D tan. U. Now, if the apparatus be slid along the tube from T′ to T, where the two images are in contact, then the diameter of the image will be equal to the distance $a\,b$; and we have, consequently, f tan. V = D tan. U. Here the quantities f and U are found by experiment; whence V, the angular magnitude of the object, becomes known in terms of D.

(4.)



The prism micrometer, when constructed in the manner now described, has this important defect, that the extraordinary image is accompanied by the prismatic colours, especially if the angle to be measured exceeds a few minutes; and hence Rochon found that he could not use it for measuring the diameters of the sun and moon. But this defect has been ingeniously remedied by M. Arago, by simply altering the arrangement of the apparatus, and giving the double prism a fixed position out of the tube and before the eye glass. By this disposition two images are formed at the focus, the centres of which are fixed points, whose distance depends on the refracting power of the crystal; and the contact of the images is produced by increasing or diminishing the magnifying power of the eye-glass, instead of altering the position of the prism. The magnifying power thus becomes the measure of the visual angle subtended by the diameter of the observed object.

Various modifications of the three principles now explained have been proposed; for details respecting which we refer to *Brewster's Treatise on New Philosophical Instruments*, or to the article "Micrometer," in the *Ency. Brit.*, by the same author; and to *Dr. Pearson's Introduction to Practical Astronomy*.

The micrometer is an instrument of the utmost importance in astronomy, and one, in fact, to which that science is as much indebted as to the telescope itself. From a paper by Mr. Townley, in the *Phil. Trans.* for 1667, it appears certain that a micrometer with a moveable wire was first constructed by our countryman Gascoigne about the year 1640, and used by him for measuring the diameters of the moon and some of the planets; but as Gascoigne, who was killed in the civil wars in 1644, published no account of his invention, the instrument was entirely forgotten, and the merit of reinventing it, and bringing it into general use, belongs to the French astronomer Azout, who published a description of it in 1667. Huygens, a few years previously, had contrived to measure the diameter of a planet by inserting in the tube of a telescope, at the focus of the object-glass and eye-glass, a slip of metal which covered exactly the image of the planet, and then deducing the diameter from the breadth of the slip, compared with the diameter of the field; and Malvasia had employed for the same purpose a reticle or network of fine silver wires, crossing each other at right angles, and dividing the field of the telescope into a number of equal squares. (For the history of the invention and successive improvements of the micrometer, see the notes by Mathieu to *Delambre's Histoire de l'Astronomie au* 18*me Siècle*, pp. 616. and 645.)

MI′CROPHONE. (Gr. *μικρος*, and *φωνη*, *a voice.*) An instrument for increasing the intensity of low sounds, by subjecting a more sonorous body than that which emits the sound to be affected by the vibrations of that body, and thereby also sounding itself.

MI′CROPYLE (Gr. *μικρος*, and *πυλη*, *a gate*), in Botany, is a perforation through the skin of a seed, over against the apex of the nucleus. It is what was the foramen or exostome of the ovule.

MI′CROSCOPE. (Gr. *μικρος*, and *σκοπεω*, *I view.*) An optical instrument which enables us to see and examine objects which are too minute to be seen by the naked eye. Microscopes are single or compound, according to the nature of their construction; a single microscope being one through which, whether it consists of a single lens or a combination of lenses, the object is viewed directly; and a compound microscope one in which two or more lenses are so arranged that an enlarged image of the object formed by one of them is magnified by the second, or by the others, if there are more than two, and seen as if it were the object itself.

Single Microscope.— This instrument is, for the most part, simply a lens or sphere of any transparent substance, which refracts the rays of light issuing from a small body placed in its focus, and gives them such a degree of convergency as is necessary for distinct vision. In order that the rays of light issuing from the several points of a very small body may produce a sensible impression on the retina of the eye, it is necessary that the object be brought very near the eye; but when this is done, the rays coming from its different points are so divergent as to produce only a confused image. Now, if a convex lens be interposed between the object and the eye, and so placed that its distance from the object is a little less than its focal distance, the diverging rays issuing from the object are refracted by the lens, and enter the eye placed behind it, either parallel, or so nearly parallel as to afford distinct vision. The object is then seen in the direction of the refracted rays, and at the distance at which it could be distinctly seen by the naked eye; and consequently magnified in the ratio of the distance of distinct vision to the focal distance of the lens. This

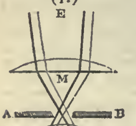
ratio is called the *magnifying power* of the lens; hence, for single microscopes, the magnifying power is equal to the distance at which a small object can be seen distinctly by the naked eye, divided by the focal distance of the lens; and, as the distance of distinct vision is constant (at least for the same individual), the magnifying power is inversely as the focal distance. If we suppose the distance which limits distinct vision, in respect of minute objects, to be 5 inches (which is about the average for good eyes), and the focal distance of the lens to be 1 inch, the object will be magnified 5 times in linear dimensions, and 25 times in superficial. If the focal distance is one tenth of an inch, the magnifying power will be 50 in linear extent, and 2500 in superficial.

A single microscope may be obtained very easily by piercing a small circular hole in a slip of metal, and introducing into it a drop of water, which will assume a spherical form on each side of the metal. The substance commonly used for microscopic lenses is plate glass; but they are sometimes formed of rock crystal, which is better. Flint glass, by reason of its great dispersive power, is unfitted for the purpose. The precious stones, as the garnet, ruby, sapphire, and diamond, have been proposed; but the numerous and skilful attempts of Mr. Varley and Mr. Pritchard have proved that the advantages arising from the greater refractive power of those substances are more than counterbalanced by their colour, reflective power, double refraction, and heterogeneous structure. The crystalline lenses of minnows and other small fishes give a very perfect image of minute objects.

When the object to be examined is of such magnitude as to subtend an angle of some degrees, the requisite distinctness cannot be given to its whole surface by an ordinary lens, in consequence of the confusion occasioned by the lateral rays; unless, indeed, the rays are only permitted to enter the lens through a very small aperture, whereby the quantity of light is greatly diminished. In order to remedy this inconvenience, Dr. Wollaston contrived a form of lens, to which he gave the name of *periscopic lens*. Its construction is as follows: — two plano-convex lenses or hemispheres are ground to the same radius, and between their plane surfaces a thin plate of metal, with a circular aperture, is introduced. The aperture which appeared to give the most distinct image was about 1-5th of the focal length in diameter; and, when the aperture was well centered, the visible field was as much as 20° in diameter. A lens of this kind possesses the double advantage of having a very short focal distance, and very little spherical aberration. Dr. Wollaston's contrivance may, however, be improved upon in various ways; for example, by filling up the central aperture with a cement of the same refractive power as the lenses, whereby the loss of light from the double number of surfaces is avoided; or by grinding away the equatorial parts of a sphere of glass, so as to leave a deep groove all round it, in the plane of a great circle perpendicular to the axis of vision, and filling the groove with opake matter. This last construction is called the *Coddington lens* (from the name of its proposer); and when executed in garnet, and used in homogeneous light, it is considered by Sir David Brewster to be the most perfect of all lenses, either for single microscopes, or the object lenses of compound ones.

In using a single lens as a magnifier, it is always necessary that the light be made to pass through a very small aperture, in order that the object may be seen distinctly and without distortion. This necessity arises, both from the spherical aberration and the chromatic dispersion of the light falling on the surface of the lens under an angle of considerable obliquity; and the consequence is that the quantity of light admitted to the eye is so much diminished that the object cannot be clearly seen. To remedy this inconvenience, Dr. Wollaston proposed a combination of two lenses, called, in consequence, *a microscopic doublet*, the optical part of which may be described as follows: — M and N (fig. 1.) are two plano-convex lenses, whose focal lengths are in the ratio of 3 to 1, or nearly so, and placed one over the other, so that their plane sides are towards the object. The adjustment of the distance between the lenses is best accomplished by trial; and they must, accordingly, be mounted so that the distance can be varied at pleasure. A B is a diaphragm or stop for limiting the aperture. Though it does not appear that the stop was contemplated by Dr. Wollaston, who makes no allusion to it, the performance of the microscope depends much on its nice adjustment. It is obvious that as each of the pencils of light from the extremities of the object is rendered eccentric by the stop, and made to pass through the two lenses on opposite sides of the common axis, they are affected by opposite errors, which, in some degree, serve to counteract each other. This doublet, when correctly made, is infinitely superior to any single lens, and will transmit a pencil of from 35° to 50° without any very sensible errors. The original description, by Dr. Wollaston, is given in the *Philosophical Transactions* for 1829.

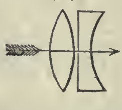
(1.)



The above construction has been improved upon by subtituting two plano-convex lenses for N in the doublet, the plane side of the one being in contact with the convex side of the other, and the stop being retained between them and the third. This combination is called a *triplet*; and its advantage is, that the errors of the doublet are still further reduced by the greater approximation to the object, in consequence of which the refractions take place nearer the axis.

Another form of doublet, proposed by Sir John Herschel, is represented in the annexed figure (2). It consists of a double convex lens, whose radii of curvature are as 1 to 6; and of a plano-concave, whose focal length is to that of the other as 13 to 5, placed in contact with the flatter surface of the former, and having its concavity turned towards the object. Many other combinations have been proposed, but those which have now been described appear to be the most useful.

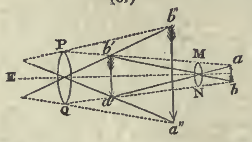
(2.)



When the magnifying power of the lens is considerable, and consequently its focal distance very small, it requires to be placed at the proper distance from the object with great precision; and, as it cannot be held in the hand with sufficient steadiness for any length of time, it requires to be mounted in a frame having a rack and screw, by means of which its distance from the object can be adjusted with accuracy. Mirrors for collecting the light and throwing it upon the object are also necessary for many purposes.

Compound Microscope. — The simplest kind of compound microscope is formed by the combination of two converging lenses, whose axes are placed in the same straight line. The arrangement of the lenses, and the path of the rays, will be readily understood from the annexed diagram (fig. 3.) M N is the object glass, which has a very short focal distance, and P Q the eye-glass. A small object $a\,b$ being placed before the object-glass, a little farther from it than the focus of parallel rays, a reversed and enlarged image $a'\,b'$ will be formed at some distance behind M N. The lens P Q is placed at such a distance from M N that its principal focus is in the line at $a'\,b'$; consequently the rays of light from every point of the image $a'\,b'$ emerge nearly parallel from P Q, and to the eye at E the image $a'\,b'$ is magnified, as if it were a real object, into $a''\,b''$, and appears at a distance equal to the limits of distinct vision, which, as stated above, is about 5 inches.

(3.)



The magnifying power of this microscope, or the ratio of $a''\,b''$ to $a\,b$, is found as follows: — In the first place, if we assume d to denote the distance of the first image $a'\,b'$ from M N, and f the distance of $a\,b$ from M N, or the focal distance of M N, we have this proportion, $a'\,b' : a\,b :: d : f$. In the second place, if l denote the limit of distinct vision, or distance of the second image $a''\,b''$ from P Q, and f' the focal distance of P Q (or distance of $a'\,b'$ from P Q), we shall also have $a''\,b'' : a'\,b' :: l : f'$. These two proportions, being multiplied together, give $\dfrac{a''\,b''}{a\ \ b} = \dfrac{d \cdot l}{f \cdot f'}$; which, therefore, is the magnifying power of the microscope. It thus appears that the magnifying power is inversely as the product of the focal distances of the two lenses, and directly as the distance between them. The magnifying power will therefore be increased by increasing the distance between the object-glass and eye-glass; but a limit is soon placed to this increase by the indistinctness of the image, and, in practice, it is not advisable to make the distance of $a'\,b'$ from M N more than from 5 to 7 inches. Suppose the focal distance of M N to be $\frac{1}{4}$th of an inch, and the distance of $a'\,b'$ from M N to be 5 inches, then $a'\,b'$ will be 20 times greater than $a\,b$; and if the focal distance of P Q be half an inch, and the distance of $a''\,b''$ from P Q be 5 inches, then $a''\,b''$ will be 10 times greater than $a'\,b'$, and, consequently, 200 times greater than $a\,b$; or the magnifying power is 200.

The great defects of the microscope, when constructed in the manner now described, consist in the smallness of the field of view, and want of achromatism in the object-glass, in consequence of which the images $a'\,b'$ and $a''\,b''$ are fringed with the prismatic colours. For the sake of enlarging the field of view, a third lens, larger than either

of the others, and called the field glass, is usually interposed between the image $a' b'$ and the object-glass.

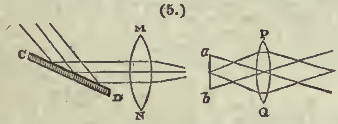
Reflecting Microscope.—The principle of the reflecting microscope is very simple, and easily conceived. Suppose M N (fig. 4.) to be a concave speculum, and a small object to be placed before it at *f*. A reflected image of the object will be formed at F, where the rays issuing from each point of the object intersect each other, and magnified in the proportion of F M to *f* M. If the image at F is viewed with the naked eye, the instrument is a single reflecting microscope; but if the image is viewed through a refracting lens P Q (or a combination of lenses forming an eye-piece), by which the rays are made to converge towards the eye at E, it becomes a compound reflecting microscope.

(4.)

The reflecting microscope was first proposed by Sir Isaac Newton in the form now described; but, on account of the impracticability of illuminating the object, it was long disused. It has, however, been recently revived, under a modified form, by Professor Amici of Modena, who places the object outside the tube of the microscope, below the line N F; and, in order that an image may be formed in the speculum, the rays issuing from the object fall upon a small plane mirror placed at *f*, inclined to the axis of the speculum in an angle of 45°, whereby they are thrown upon the speculum in the same manner as if the object itself were placed at *f*. By this means the object can be illuminated with perfect facility. The concave speculum M N is ground into an ellipsoidal surface; the diagonal mirror is placed at the nearest focus *f*, and the image is consequently formed at the other focus F. The image at F is viewed with a single or double eye-piece, as in other microscopes.

Solar and Oxyhydrogen Microscopes. — The solar microscope is composed essentially of a mirror and two converging lenses. The plane metallic mirror, C D (fig. 5.), reflects the sun's rays upon the lens M N, by

(5.)



which they are concentrated upon the object *a b* placed in its focus. The object, being thus strongly illuminated, is placed before a second lens P Q (a little before the principal focus), by which the rays are rendered still more convergent, and produce a magnified image of the object upon a screen suitably placed at a distance of some feet behind the lens. The object is here supposed to be transparent; if opake, the light must be thrown upon it in such a manner as to be reflected by it to P Q. The mirror and lens M N are placed in the hole of a window shutter in a darkened room; and the mirror must be moveable, in order that the sun's rays may always fall upon it under a proper angle to be reflected to the lenses. But the solar microscope is now almost entirelysuperseded by the *oxyhydrogen microscope;* so called because the illumination, instead of being produced by the sun's rays, is produced by burning a small piece of lime or marble in a stream of oxyhydrogen gas. In this case the plane mirror C D becomes unnecessary; and instead of the lens M N a concave speculum is employed, in front of which the ball of lime is placed, and an intense light thus thrown upon the object *a b*, the rays from which are brought to foci upon the screen by the lens P Q. For full details respecting the management of this apparatus, which forms a very popular exhibition, the reader is referred to *Goring and Pritchard's Micographia*. For descriptions of the various kinds of microscopes, see *Brewster's Treatise on New Philosophical Instruments;* or the *Ency. Brit.*, art. "Microscope."

MI'DDLE AGES. (In French, *moyen age*.) A term usually employed to denote, somewhat vaguely, a space of several centuries in European annals, intervening between what are called the ancient and modern periods of history. The centuries between the ninth or tenth and the end of the fifteenth after Christ are generally comprehended under this loose denomination. In the work of Mr. Hallam on the *Middle Ages*, that historian has assumed as his period of commencement the conquest of Gaul by the Franks, about A. D. 500; and, for his conclusion, the invasion of Italy by Charles VIII., about 1500; and with reference to the affairs of the Greeks and their oriental neighbours, he places, as the most convenient limit between ancient and modern history, the era of Mohammed.

MI'DDLE CADENCE. In Music. *See* CADENCE.

MI'DDLE LATITUDE SAILING, in Navigation, is a method of converting the departure (or distance on the parallel) into difference of longitude, and the difference of longitude into departure, when the ship's course is oblique to the meridian. It is founded on this principle, which, however, is only approximately true in any case, and not even approximately in high latitudes, when there is also considerable difference between the latitudes left and arrived at; namely, that the departure may be accounted an arc of a parallel of latitude midway between the two extreme latitudes. Its rules are,—

radius : cos. middl. lat. : : diff. longitude : departure,
cos. middl. lat. : tan. course : : diff. lat. : diff. long.

See NAVIGATION.

MI'DDLE RAIL. In Architecture, the rail of a door level with the hand, on which the lock is usually fixed.

MI'DDLE TERM of a Categorical Syllogism, in Logic, is that with which the two extremes of the conclusion are separately compared. *See* SYLLOGISM.

MI'DSHIPMAN. In the Navy, the step next above volunteer of the first class, which is generally the commencement. At nineteen years of age the midshipman passes one examination in seamanship, and another in navigation, when he becomes eligible for a lieutenant's commission.

MIDSHIPS. The middle of the ship, with reference to length or breadth.

MI'EMITE. A magnesian carbonate of lime of a green colour from Miemo, in Tuscany.

MIGRA'TION. (Lat. migro, *I migrate.*) This word is used in Zoology to signify the transit of a species of animals from one locality or latitude to another. The passage is usually to and fro between a temperate and a cold climate, or a temperate and a warm climate; and this periodical change of abode is most general in the arctic species of animals, and least prevalent in the tropical species. The most remarkable, rapid, and extensive migrations are performed by birds, in virtue of their preeminent locomotive powers, and of their ability to maintain a long and rapid flight through a medium which offers the least opposition to their progress. The inequalities and alternations of land and water upon the surface of the earth, and the presence of enemies and other dangers, would appear to form insurmountable obstacles to any general or extensive migration of quadrupeds; yet the musk-ox, the rein-deer, the arctic fox, &c., are driven southward by the rigours of the polar winter, and return to the extreme latitudes in the summer season. Less regular, but not less general migrations, take place among the quadrupeds which range the tropical continents in seasons of unusual drought. Countless herds of oxen, goaded by intolerable thirst, are thus impelled in an irresistible course over vast tracts of the South American Pampas in quest of water. The valleys of the warmer parts of Africa are occasionally traversed by numerous assemblages of the wild quadrupeds of that continent, migrating under the same stimulus. Lions and other carnivora have on these occasions been seen mingled with, and absolutely hemmed in by, the countless assemblage of antelopes, gnus, and other herbivorous species which constitute their prey. The Scandinavian lemming, however, is the species of quadruped that is most remarkable for its migration. But the migratory periods are not regular; nor are the immense bodies that travel in a given direction ever known to return. In this respect the migration of the lemmings resembles rather that of the locusts among insects than the true and regular migration of birds. The ordinary residence and breeding-place of the lemmings appear to be the shores of the arctic ocean. Here, when their numbers exceed the means of subsistence, they congregate together, and commence a migratory course southward, moving in a straight line, crossing rivers, climbing mountains; and while no insurmountable obstacle impedes their progress, they devastate the country through which they pass. The migration of birds appears to be influenced mainly by the necessity of providing sufficient food for their young, and by the temporary continuance of such food in the climates best suited for propagation.

The arctic and northern seas, which teem with life during the long unbroken day that constitutes the summer season of such latitudes, are resorted to by numerous aquatic birds during the breeding season; and these birds regularly migrate southward when the severities of winter set in. In temperate latitudes, as those of England, certain spring and summer months are peculiarly favourable to the production of insects in their different stages; and our island is accordingly frequented by many insectivorous birds, which leave warmer latitudes during these months to breed and rear their young with us. As a general rule, it may be stated that birds migrate southward in the northern hemisphere for food principally; but that they migrate northward both to feed and breed. The most remarkable summer immigrants that visit England from the south and breed in this island are the swifts, swallows, cuckoo, nightingale, and many other insectivorous Passerine birds; and it is remarkable that the males of the song birds always precede the other sex in their vernal flight.

The winter immigrants from the north are the species of wild swan; many species of wild duck; the smews, merganser, and other aquatic birds; the woodcock, &c. It occasionally happens that a winter immigrant remains with us the whole summer, and breeds. Thus the woodcock's eggs and young have occasionally been taken in our woods; but this is an exceptional or individual case. It is a rare occurrence when a summer immigrant prolongs its sojourn into the winter months, as happens when by late hatching, or debility produced by accident or disease, a swallow or martin has been prevented from joining the main body of autumnal emigrants of its own species, and is seen flying about when an unusually mild day may have called some insects abroad in the months of November or December.

The season of migration is that of association, both in birds and other animals. The swifts congregate for their departure about the middle of August; the swallows assemble together for the same purpose in September. Their powers of flight are more than equivalent to the extent of space they have to traverse to reach the warmer latitudes, as the Mediterranean shores of Africa, where they have been seen in those months when they have disappeared from us. Yet there have not been wanting naturalists who have believed that the life of the swallow was maintained during the absence of its insect food in England by the same torpidity which enables the bat and hedgehog to exist through the winter, and resume their vital functions in spring. The burrows of the sand-martin have been explored in winter with this view; but neither there nor in any other hiding-place has a torpid martin or swift been ever found. It was next conjectured that these birds went under water in autumn, and passed the winter not only torpid, but submerged. The supporters of this theory, however, have neither explained how the difference of specific gravity which makes the body of a swallow float upon water was overcome, nor how the extravascular plumage was preserved undecomposed and fit for use after six months' soaking in water.

The short migrations of the cuckoo and nightingale are unquestionable: why should the longer migrations of summer-breeding birds of greater powers of flight be doubted? The direct observation of swallows in the act of migrating, and the slowly acquired but certain knowledge of their winter resort, have finally put to rest the scepticism as to the migration of the swallow tribe, which only the authority of such eminent naturalists as White of Selborne could have so long rendered excusable in works of Zoology.

MI'LDEW. This term is generally applied to a particular mouldy appearance on the leaves of plants, which is produced by innumerable minute fungi, which, if not checked in their growth, will occasion the decay and death of the parts on which they grow, and sometimes of the entire plant. In agriculture, this appearance is frequently termed rust, and sometimes blight. It is common on wheat, and on the hop; and in gardens on the leaves of the peach, the nectarine, and other fruit trees. The causes favourable to the production of mildew are a rich soil and a moist atmosphere, without a free circulation of air or sunshine. In agriculture, this parasitical disease is generally considered without remedy; but, in gardening, it may be checked by the application of powdered sulphur to the leaves covered by the fungi, which is found to destroy them without greatly injuring the leaf. Dry-rot is only mildew of a more formidable kind.

MILE. (Lat. mille passuum, *a thousand paces.*) The Roman pace being 5 feet, and a Roman foot being equal to 11·62 modern English inches, it follows that the ancient Roman mile was equivalent to 1614 English yards, or very nearly 11-12ths of an English statute mile.

The English statute mile was defined (incidentally, it would seem) by an act passed in the 35th year of the reign of Queen Elizabeth, by which persons were forbidden to build within three *miles* of London; and the mile was declared to be 8 furlongs of 40 perches of 16½ feet each. The statute mile is, therefore, 1760 yards, or 5280 feet. *See* MEASURES.

The mile is used as an itinerary measure in almost all countries of Europe, particularly those which were formerly under the sway of the Romans; but it is very difficult to conjecture the causes which have given rise to the great diversity of its values. It has been supposed that in some countries the Roman mile was confounded with the ancient Celtic league.

The following table, given on the authority of *Kelly's Cambist*, shows the length of the modern mile, and also the league, of various countries, and their relation to the English statute mile.

	Yds.	Stat. Miles.
Modern Roman mile	1628	·925
English statute mile	1760	1·000
Tuscan mile	1808	1·027
Ancient Scottish mile	1984	1·127
Irish mile	2240	1·273
French posting league	4263	2·422
Spanish judicial league	4635	2·634
Portugal league	6760	3·841
German short mile	6859	3·897
Flanders league	6864	3·900
Spanish common league	7416	4·214
Prussian mile	8237	4·680
Danish mile	8244	4·684
Dantzic mile	8475	4·815
Hungarian mile	9113	5·178
Swiss mile	9153	5·201
German long mile	10126	5·753
Hanoverian mile	11559	6·568
Swedish mile	11700	6·648

According to the same authority, the Arabian mile is 2148 yards, the Persian parasang 6086 yards, the Russian werst 1167 yards, and the Turkish berri 1826 yards. The English geographical mile is 1-60th of a degree of latitude, or about 2025 yards; the geographical league of England and France is 3 such miles, or 6075 yards; and the German geographical mile is equal to 4 English geographical miles, or 8100 yards. See an excellent disquisition on the history of the English mile in the *Penny Cyclopædia*.

MILIA'RIA. (Lat. milium, *millet seed.*) A disease attended by an eruption resembling millet seed. Miliary fever.

MILIEU (JUSTE)—PARTY OF THE. A French party nickname, arising, it is said, out of a casual expression of King Louis Philippe, but which has obtained a notoriety rather greater than such ephemeral phrases usually acquire. It has served to denote the great party opposed to the Carlists, or Legitimists, on the one hand; and to the extreme left section of the Chamber of Deputies, with its allies the Republicans, on the other. After the overthrow of the feeble ministry of Lafitte in March, 1831, Casimir Périer was authorized to form a new cabinet; and his administration seems to have realized more than any other the ideal of a government of the Juste Milieu. Under its rule the hereditary peerage was abolished; the continual street disturbances which had almost controlled the will of the previous ministry quelled; Ancona seized; and the foundation of the successful intervention of France in the Hollando-Belgic quarrel laid. Périer died of cholera on the 16th of May, 1832. After a short interval he was succeeded by Soult; who has been perhaps, since that time, more identified with the Juste Milieu party than any other minister: Molé, Guizot, Dupin, Thiers, Barrot, the most eminent statesmen of France, having each of them adopted a line and formed to a certain extent a party of his own, alternately aided and opposed by the great body of the partisans of the Juste Milieu.

MILI'OLA. (Lat. milium, *a millet-seed.*) The generic name applied by Lamarck to an extinct mollusk, or zoophyte, which has left its small forameniferous multilocular shell in great numbers in the strata of many quarries in the neighbourhood of Paris.

MILI'TIA. A body composed of citizens regularly enrolled, and trained to the exercises of war; but not permanently organized in time of peace, or, in general, liable to serve out of the country in time of war. Such an establishment exists in most European countries under different names. (*See* GUARD, NATIONAL.) In Austria and Prussia it is called landwehr; and in the latter country receives full pay during a certain part of every year when it is in exercise. Various and unsuccessful efforts were made by German sovereigns, during the wars of the last century, to organize bodies of troops which should be as cheaply raised as militia, and yet be serviceable in foreign war. Frederick the Great used such troops for garrison service. The militia of England and Scotland now consists of a certain number of men in every county, drawn by lot to serve for five years, and liable to be called out and embodied, on danger of rebellion or invasion, by proclamation of the king in council, and with notification to parliament, if that body is sitting. During the late war, the militia was kept constantly on foot and might be sent to any part of the kingdom; so that it differed little from the regular army, except that it could not be sent abroad, and that it was recruited by ballot. But, in addition to the above, a militia called local, or fencibles, in many instances raised and supported entirely at the expense of some great landed proprietor, was established in every county. After the peace of 1815 the militia was disembodied; but, as we remarked above, it is still liable, if it be considered necessary, to be called out. In Prussia every man who has served his three years, or a single year in certain cases, of lawful service in the standing army, belongs to the first class of the landwehr until his thirtieth year; and from that time until his fortieth to the second class.

MILK. (Germ. milch.) A fluid secreted by peculiar glands in the breasts of the class of animals called *Mammalia*, and destined for the nourishment of their young.

The obvious components of milk are cream, curd, and

whey, — 1000 parts of cream (of cow's milk), of the sp. gr. 10244, consist, according to Berzelius, of

Butter	45
Curd	35
Whey	920
	1000

The remaining skimmed milk has a specific gravity of about 1033, and consists of

Water	929
Curd with a trace of butter	28
Sugar of milk	35
Lactic acid, lactate of potash, and a trace of lactate of iron	6
Muriate and phosphate of potash and earthy phosphates	2
	1000

If we subtract the curd, the remaining substances constitute whey. The *curd* of milk, or *caseous matter*, partakes in many of its chemical properties of the nature of albumen; in others it resembles vegetable gluten, more especially in the fermentation which it undergoes when kept in a moist state. *Sugar of milk* is obtained by evaporating whey. When purified it has a sweet taste, and requires 7 of cold and 4 of boiling water for solution, and is insoluble in alcohol: when digested with nitric acid it is partially converted into mucous, or *saccholactic acid*, and not, like common sugar, into oxalic acid. This, therefore, though an animal product, closely resembles the vegetable proximate principles; and milk may hence be considered as partaking of the nature of vegetable as well as animal food. *See* Dairy.

MILK FEVER. *See* Puerperal Fever.

MILK TREE, so called from its trunk yielding a milky fluid when wounded, is a name applied more particularly to those species in which the fluid is harmless and fit for food; an uncommon circumstance among lactescent plants, whose secretions are generally dangerous. In the Caraccas there is one sort, the *palo de vaca*, or cow tree of Humboldt, whose milk is a common article of diet among the natives; this is the *Galactodendron utile*. In that and other countries, plants of the Sapotaceous order, especially species of Achoas, also furnish such a secretion. In Ceylon has been found the Kiriaguni plant, or *Tabernæmontana utilis*, which is used by the Cingalese in a similar manner.

MILK VESSELS, in Plants, are the anastomosing tubes lying in the bark, or near the surface of plants, in which a white turbid fluid is secreted. They are one of the forms of the *vital veins* of Schultz, which see.

MI'LKY WAY, or VIA LACTEA, or GALAXY. A broad and irregular zone of stars that surround the heavens, so distant that their united light gives but an indistinct and undefined whitishness to the whole appearance — whence its name. *See* Galaxy.

MILL. (Gr. *μυλη*; Lat. mola.) This term seems to have signified originally an engine for grinding corn, but it is now used in a general sense to denote a great variety of machines, whose action depends chiefly on circular motion. The particular purpose is usually indicated by a prefix; thus, bark-mill, cotton-mill, flour-mill, oil-mill, saw-mill, spinning-mill, &c.

The machinery by which it is necessary to accomplish the ultimate objects of the mill must obviously vary almost indefinitely. Many voluminous works on this subject have been published, as well as separate accounts of particular structures. See Brewster's edition of *Ferguson's Lectures*; *Gray's Experienced Millwright*; *Buchanan on Millwork*, by Tredgold; *Banks on Mills*; *The Repository of Arts*, &c. A catalogue of the principal works on the subject of mills is given in *Gregory's Mechanics*, vol. ii.

MILL, BARKER'S. *See* Centrifugal Machine.

MILLE'NNIUM. (Lat. mille anni, *a thousand years*.) The reign of Christ with his saints upon earth for the space of a thousand years; an idea derived from a passage in the 20th chap. of the Apocalypse, and not uncommonly entertained by Christians in all ages, but especially in the times of the primitive church. The opinion seems to be traced as far back as to Papias, a father of the second century. It is the subject of much discussion among the writers of that and the succeeding ages; was maintained by Justin Martyr, Irenæus, Tertullian, and many others, and powerfully refuted by Origen. (See the work of *Alstedius*, translated by Bruton, 1643; *Gibbon*, ch. xv., with Milman's notes; Bertholdt, *Christologia Judæorum*; Eisenmenger, *Das Entdeckte Judenthum*; *Lightfoot*; *Mosheim*, vol. i.)

MI'LLEPORES, *Millepora*. (Lat. mille, *a thousand*, porus, *a pore*.) A tribe of Lithophytous Polypes, including those in which the calcareous axis is perforated by extremely numerous pores.

MI'LLET. (Lat. milium; Fr. millet.) A plant classed by botanists among the grasses, though some of its species attain a height of from 16 to 20 feet in favourable situations. There are many species of this plant; of which the principal are the Polish, the common or German, and the Indian millet. In several parts of Europe it is cultivated as a grain, and is sometimes employed as a substitute for rice or sago by the poorer classes, but more frequently it is used for feeding chickens and domestic animals. It is cultivated to a considerable extent in France, Switzerland, Southern Germany, and most extensively in Egypt, Syria, Nubia, China, and Hindostan; but the climate of England is not sufficiently dry and warm to allow of its being cultivated here.

MI'LLION. A thousand thousand, or, as often defined, ten hundred thousand. *See* Numeration.

MILLSTONE GRIT. A geological term applied to a group of strata which occur between the mountain limestone and the superincumbent coal formations; it is a coarse-grained quartzose sandstone.

MI'LVINES, *Milvini*. A family of Raptorial birds, of which the kite (*Milvus*) is the type.

MIME. (Lat. mimus; Gr. *μιμος*, from *μιμεομαι*, *I imitate*.) The name given by the ancient Greeks and Romans at once to a species of dramatic entertainment, and to the authors and actors by whom it was respectively composed and performed. It consisted chiefly of a rude representation of common life, and resembled the modern farce or vaudeville in its character and accompaniments. Sophron of Syracuse, who lived about 400 years before the Christian era, is considered the inventor of this species of composition. His pieces were read even with pleasure by Plato, who is said to have introduced this kind of dramatic entertainment into Athens. (The *Museum Criticum*, No. 7., contains several fragments of mimes by Sophron.) At what period mimography was first practised at Rome cannot be precisely ascertained; but in the time of the emperors, and even under Augustus, this species of entertainment had attained a high degree of popularity. Among the Romans, it was of a still more farcical character than among the Greeks, from whom it was borrowed, and bordered more upon such mountebank representations as *Punch and Judy* among ourselves, and the *Fantoccini* of the Italians. Mimes originally formed a part of the usual theatrical exhibitions; but they were soon introduced by the wealthy Romans into their private entertainments to divert their guests. At Rome they also held a prominent place at funerals, on which occasions their duty consisted in praising the virtues and exposing the defects of the deceased. It is, however, very probable that less licence of caricature was then admissible; but the highest rank was not exempt from the practice. Thus, Suetonius tells us that the archmime Favo was present at the funeral of Vespasian: — "Sedet in funere Favo archimimus, personam ejus ferens, imitansque, ut mos est, facta et dicta vivi."

MI'MUS. (Lat. *a mimic*.) A genus of Passerine birds, separated by Boié from the thrushes (*Turdus* of Linnæus) on account of the more elongated form of the body, and particularly of the tail, the shorter wings, and more curved upper mandible. The type of this genus is the celebrated mocking-bird. See that word.

MI'NA. (Gr. Μνᾶ.) A weight and coin in use among the Greeks, but which was different in different states. The Attic mina, which is that most frequently mentioned, was heavier than the Roman pound by about four drachmæ. Each mina contained 100 drachmæ, and was itself contained 60 times in an Attic talent. The coin was worth a little more than 3*l*. of our money.

MI'NARET. (Arab. menarah, *a lantern*.) A slender and lofty turret in the mosques of Mohammedan countries, used for the purpose of summoning the people to prayers, and consequently answering the purpose of the belfry in Christian churches. They are usually surrounded with projecting balconies, and are crowned with spires surmounted by a crescent. Before the hour of prayer the criers of the mosques ascend the minarets, whence they summon the people to prayers with the words, "Come, ye people, to the place of rest and integrity; come to the asylum of safety."

MINDERE'RUS'S SPIRIT. Solution of acetate of ammonia, first recommended as a febrifuge by Raymond Mindererus, a physician of Augsburg.

MINE. The name given generally to every system of subterraneous work or excavation which has for its object the discovery and extraction of the metallic ores or other mineral produce. But, in addition to the underground works which constitute the mine properly so called, the term usually comprehends also the ground on the surface, together with the numerous appendages which are required there; as steam-engines, water-wheels, and other machinery for drainage, the extraction of the ores, and their mechanical preparation, with various buildings and erections. The subject of mines is one of the most important within the whole range of human knowledge: their contents constitute the main-springs of civilization; and the means employed to obtain them are to be ranked among the most extraordinary instances of human enter-

prise, patience, and ingenuity. The art of mining has been practised from the earliest antiquity, and has formed a branch of industry to the most barbarous as well as the most civilized communities. It is true that we can scarcely dignify by the name of mining the operation by which the savage merely collects grains of gold in the sands of rivers, or extracts it by pounding, when mechanically combined with other substances; but even this simple operation becomes interesting, when viewed as the first link in the chain of those elaborate and scientific processes now employed in the extraction of metallic and other mineral substances from the bowels of the earth. In England, mining had a very early origin, compared with the progress of other arts in the country. It was, in all probability, the first source of trade to these islands; and so celebrated was British tin over the whole of the then known world, that the Phœnicians traded to Cornwall for this metal. At that early period, however, and indeed for centuries afterwards, the art of mining was necessarily in a comparatively rude and imperfect state, arising from the want of an effective means of drainage and of blasting implements; and it was not until hydraulic machines were applied to raise the waters which accumulated in mines of every description that metals could be followed to any considerable depth, and not until gunpowder had furnished the means of splitting the hardest rock that the miner was enabled to surmount the obstacles which the most indurated strata opposed to his progress. These inventions, therefore, may be regarded as most important epochs in the history of mining: but the *present* comparatively perfect state of the art is mainly owing to the invention of the *steam engine* and the improved manufacture of iron, which took place in the latter part of last century. The former gave to the miner a power capable of universal application, and of an effect that added, as it were, new regions of subterranean country to his control; while the latter has proved no less important in contributing to the same result, by the improved machinery and apparatus it has placed within his reach.

The art of mining embraces such an infinity of topics and processes, differing from each other in proportion to the difference of the locality of the lodes, the habits of the population, and the character and the resources of the country in which it is practised, many of which, besides, are of so abstruse and complicated a nature as to be utterly unintelligible without the most lengthened details, and the introduction of numerous diagrams that would have been foreign to the object of this work, that we shall refrain from entering upon a subject which it would be impossible for us to treat satisfactorily in this place. We must therefore refer the reader to *Ure's Dict. of Arts, &c.*, which contains full details upon the numerous processes connected with this most important art, and content ourselves with subjoining the following tables: the one made up from the *Geo. Dict.*, containing an estimate of the mineral produce of Great Britain on an average of years and prices; the other being a Comparative Table of celebrated Mines in Europe and America, which we have borrowed from the *Quarterly Mining Review* for July, 1835, p. 60. (The various mining terms, as *shaft*, *lode*, &c., will be found defined under their respective heads; and the different metallurgical processes explained under the separate metals.)

Estimate of the Mineral Produce of Great Britain, on an Average of Years and Prices.

	Quantity.	Value.
Silver	10,000 lbs. troy	£30,000
Copper	13,000 tons	1,300,000
Tin	5,500	550,000
Lead	46,000	950,000
Iron	1,250,000	10,000,000
Coal	32,000,000	12,000,000
Salt, alum, and other minor produce more than		1,000,000
Total value probably exceeds		£25,830,000

COMPARATIVE TABLE of celebrated Mines in Europe and America. By J. Burt, Esq.

	CONSOLIDATED AND UNITED MINES. (At present the richest mines in Cornwall.)	VETA GRANDE MINES. (At present the richest mines in Mexico.)	MINE OF VALENCIANA. (Richest of the Mexican mines at the beginning of the present century.	MINE OF HIMMELSFURST. (Richest of the Saxon mines at the beginning of the present century.
Situation	Two miles east of Redruth.	Four miles north of Zacatecas.	One mile north of Guanaxuato.	Two miles south-east of Freyberg.
Elevation	Elevation of the surface above the level of the sea, from 200 to 300 ft. Depth of the bottom of the mine below the level of the sea, about 1370 feet.	Elevation of the surface above the level of the sea, supposed to be about 6000 feet. Elevation of the bottom of the mine above the level of the sea, probably near 5000 feet.	Elevation of the surface above the level of the sea, 7617 feet. Elevation of the bottom of the mine above the level of the sea, 5730 feet.	Elevation of the surface above the level of the sea, 1346 feet. Elevation of the bottom of the mine above the level of the sea, 263 feet.
Nature of the rock	Primary clay slate resting immediately on granite, a short distance westward of the mines. The clay slate is intersected by numerous channels of porphyry, which have nearly the same direction as the mineral veins, and are often of considerable width. The porphyry sometimes appears also to form large irregular masses in the clay slate. Both rocks are traversed by veins of quartz and clay intersecting the metalliferous veins.	Transition clay slate, alternating with dolomite, and occasionally with greywacké. This clay slate is sometimes decomposed; it rests on syenitic rocks, and is in some places covered with porphyry.	The *Veta Madre* of Guanaxuato, upon which this mine is worked, traverses both clay slate and porphyry, but it is most productive in the former rock. The clay slate is considered by Humboldt to belong to the transition class, but situate near the limits of primary formations. This rock in depth passes into chlorite slate, and talc slate. It contains subordinate beds of syenite, hornblende slate, and serpentine. The porphyry rests upon the clay slate, and is conformable to it, both in direction and stratification.	The rock prevailing in the neighbourhood of Freyberg, in which this and most of the other mines are situate, is a formation of primary gneiss.
Nature of the metalliferous deposits	In the consolidated mines, the eight following lodes are extensively worked:—Wheal Fortune lode, Cusvea lode, Deeble's lode, Old lode, Taylor's lode, Tregonning's lode, Martin's lode, and Glover's lode. In the united mines, the principal workings are upon the Old lode, and about five or six others are more or less productive. Numerous smaller lodes or "branches" occur also in both mines. The principal lodes are from 2 or 3 to 7 or 8 feet wide; the "branches" are generally 12 or 18 inches wide. The direction of the lodes varies from nearly east and west to about 20 degrees north of east and south of west. The underlie of the principal lodes is from 2 to 3 feet per fathom north, that of the smaller ones about the same south.	One principal vein (the *Veta Grande*), which is generally separated into 3 branches, and sometimes into four. When ramified, the width extends to 60 or 70 feet; when united, it varies from 8 or 10 to 20 or 30 feet. The branches are generally about 10 or 12 feet wide, and the upper one is most productive. The direction of the Veta Grande is from 30 to 40 degrees south of east, and north of west, and its underlie, from two to three feet per fathom south. Other veins of less size occur in the neighbourhood of the Veta Grande, which cross it at an acute angle. One of these appears to heave the vein for about 700 feet, being the most remarkable derangement of the kind on record.	One Veta (the *Veta Madre*), which is often separated into three branches, extending from 130 to 160 feet in width. When not ramified, its width varies from 20 or 30 to 60 or 70 feet, but is more commonly from 40 to 50 feet. The direction of the vein is north-west and south-east; its underlie is south, and about 5 or 6 feet per fathom.	There are five veins worked in this mine. The principal vein (*Teichflache*) is from 1 foot 6 inches to 3 feet in width; the others are from 6 to 12 inches wide. The direction of this vein is nearly north and south; its underlie is west, and about 3 feet per fathom. Some of the other veins intersect it.

TABLE — *continued.*

	CONSOLIDATED AND UNITED MINES. (At present the richest mines in Cornwall.)	VETA GRANDE MINES. (At present the richest mines in Mexico.)	MINE OF VALENCIANA. (Richest of the Mexican mines at the beginning of the present century.)	MINE OF HIMMELSFURST. (Richest of the Saxon mines at the beginning of the present century.)
Ores - -	Chiefly copper ore, occasionally native copper, blue and green carbonate of copper. Tin, or oxide of tin, also occurs, but not in very great abundance.	Chiefly red silver, native silver, sulphuret of silver, and argentiferous pyrites.	Sulphuret of silver, native silver, prismatic black silver, red silver, native gold, argentiferous galena.	Argentiferous sulphuret of lead, native silver, sulphuret of silver, red silver.
Produce of the ores -	9½ per cent. of fine copper; average produce in 100 parts of ore.	3½ oz. per quintal.	Four ounces of silver per quintal of 100 lbs. Equivalent to 2½ parts of metal in 1000 of ore, or ¼ per cent.	Six to seven ounces of silver per quintal of 100 lbs. Equivalent to from 3¾ to 4⅜ parts of metal in 1000 of ore, or from 3-8ths to nearly ½ per cent.
Veinstone - -	Chiefly quartz, of which many varieties occur.	Chiefly quartz, occasionally amethyst, carbonate of lime, and sulphate of barytes.	Quartz, amethyst, carbonate of lime, pearlspar, and hornstone.	Quartz, pearlspar, and calcareous spar.
Mineral substances accompanying the ores - - -	The ores are generally accompanied by "gossan"* in the backs of the lodes, by blende, and by iron, and arsenical pyrites in depth.	The ores are generally accompanied by blende, sulphuret of antimony, and iron pyrites.	The ores are accompanied by blende, spathose iron, copper and iron pyrites.	The ores are accompanied by blende, spathose iron, and a little iron and arsenical pyrites.
Depth of the principal shafts - -	*Woolf's engine-shaft*, 248 fathoms; Pearce's *engine-shaft*, 275 fathoms. Some of the other engine-shafts are scarcely inferior in depth.	*Tiro General*, 182 fathoms; *Gallega* shaft, 138 fathoms.	*Tiro General*, 310 fathoms.	*Frankenschacht*, 180 fathoms.
Depth of adit at the principal shafts -	At Woolf's engine-shaft, 13 fathoms. The average depth of the adit at the other engine-shafts is about 30 or 40 fathoms.	There is no adit to this mine.	There is no adit to this mine.	The adit at the shaft called *Frankenschacht* is 47 fathoms in depth.
Quantity of water -	Varies from 2000 to 3000 gallons per minute.	About 80 gallons per minute.	The Valenciana was a dry mine from its commencement in 1760 to 1780, when it first became troubled with water, in consequence of some of the workings being inadvertently communicated with the adjoining mine of Tepeyac; which, although upon the same vein, was extremely wet. The quantity of water raised during the late working appears to have been about 110 gallons per minute, but the regular influx was much less.	50 gallons per minute.
Height to which the water is raised -	About 230 fathoms at the Consolidated Mines; at the United Mines about 110 fathoms.	On an average about 150 fathoms.	310 fathoms.	133 fathoms.
Power employed in drainage - -	9 steam-engines; 3 of 90-inch cylinder, 3 of 85, 1 of 80, and 2 of 65. A water wheel 48 feet in diameter.	Usually 10 malacates.†	A steam engine of 30-inch cylinder, and 7 malacates.	Two water wheels, each 42 feet in diameter.
	Average of the last Ten Years.	Average of the last Six Years.	Average year at the end of the Eighteenth Century.	Average at the end of the Eighteenth Century.
Probable equivalent in acual horse-power - -	1500 constantly at work, or a total number of above 4500.	32 horses constantly working, or a total number of about 100 horses.	65 horses constantly at work, or a total number of about 200.	16 horses constantly at work, or a total number of about 50.
Average annual expense in drainage	12,700*l.*, taking the average of the last ten years.	20,000*l.* per annum.	About 40,000*l.* per annum.	Cannot be ascertained, but evidently very small.
Quantity of ore annually produced -	16,400 tons of copper ore, a few tons of tin ore.	21,380 tons of silver ore.	32,500 tons of silver ore.	630 tons of silver ore.
Produce in metal -	1517 tons of fine copper, a little tin.	153,000 lbs. troy of silver.	221,900 lbs. troy silver.	6160 lbs. troy of silver.
Total returns, or value of the above	119,800*l.*	423,400*l.* per annum.	About 600,000*l.*	About 18,000*l.*
Total costs of the mine - - -	93,500*l.* exclusive of lord's dues; 98,500*l.* including lord's dues.	252,170*l.* per annum.	197,900*l.* per annum.	9500*l.* per annum.
Clear profit to the proprietors -	21,000*l.* per annum.	171,240*l.* per annum.	118,750*l.* per annum.	3560*l.* per annum.
Amount of capital invested - -	75,000*l.*	130,000*l.*	Cannot be ascertained, but known to have been very small.	Cannot be ascertained, but probably very small.
Interest on capital invested - -	280 per cent. after paying back the original capital.	Nearly 700 per cent. after paying back the original capital.	Not known, but certainly many hundred per cent.	Not known, but probably very high.
Proportion of costs to returns - -	Costs exclusive of lord's dues, 78 per cent.	About 59½ per cent.	Costs 60 per cent. In the nine years following the proportion was 80 per cent.; at the end of that time the working of the mine was stopped by the revolution in the year 1809.	Costs 73 per cent.
Number of men employed - -	About 2500 persons, of whom about 1450 are employed under ground.	About 900, of whom nearly 600 are employed under ground.	3100 Indians and Mestizoes, of whom 1800 are employed under ground.	700 miners, of whom 550 are employed under ground.
Wages of the miners per day - -	Probably about 3 shillings on an average.	About 8 or 9 shillings per day.	From 4 to 5 shillings.	About 1*s.* 6*d.* per day.
Quantity and expense of powder	- - -	- - -	1420 cwt.; value 15,830*l.*	240 cwt.; value 1070*l.*
Manner in which the ores are disposed of - -	Sold to the smelting companies, and smelted by them at Swansea, in South Wales.	Chiefly reduced by the company at the Hacienda of Sanceda, by smelting and amalgamation.	Sold to the *Rescatadores*, and reduced by smelting and amalgamation at Haciendas, in the neighbourhood of Guanaxuato.	Delivered to the Government reduction works in the neighbourhood of Freyburg, where they are partly smelted, and partly amalgamated.

* Gossan, or Gozzan; oxide of iron and quartz.   † Malacate; a horse whim.

Mines and Minerals, Law of. By the law of England all minerals are part of the freehold of the soil under which they are found, with the exception of gold and silver, which are said to belong to the crown. But, by 1 W. & M. c. 50., no mine of copper or lead is adjudged a royal mine, though silver be extracted. A lease of land, with mines mentioned, conveys, it is said, the right to carry on open mines only, and not open new ones, unless expressly reserved; but that, if there are no open mines, the lessee may then dig new ones, as otherwise the grant would be of none effect. But, unless the lessee be authorized, to dig mines is waste. Mines are not rateable to the relief of the poor, with the exception of coal mines; the latter being expressed in the statute of Eliz., the former are held to be excluded by implication. But quarries are rateable; and the distinction between a mine and a quarry is taken to be, not the nature of the mineral extracted, but the mode of working: thus, a mine of limestone worked by a shaft is not rateable. The law of mines and minerals is subject to a variety of local customs, of which those of Devon and Cornwall are the most remarkable. *See* Stannaries.

Mine. In Fortification, a subterraneous passage leading to a chamber underneath any place intended to be blown up by gunpowder. See *Müller's Art of War*, and other works on military engineering of subsequent date.

MI'NERAL ADIPOCERE. A greasy bitumen, found in the argillaceous ores of iron. *See* Hatchetine.

MI'NERAL CAOUTCHOUC. The elastic bitumen found at Castleton in Derbyshire.

MI'NERAL CHAMÆLEON. *See* Manganese. A manganesate of potash, obtained by fusing a mixture of nitre and black oxide of manganese. So called from the variety of colours which its aqueous solution successively exhibits.

MI'NERAL GREEN. Carbonate of copper, obtained by precipitating a hot solution of sulphate of copper by carbonate of soda.

MINERALI'ZERS. The substances with which metals are combined in their ores. Thus, in the native oxides, oxygen is called the mineralizer; sulphur is also a very common mineralizer, as in the ores of copper, lead, &c.

MINERA'LOGY. A branch of physico-chemical science, which teaches the properties, composition, and relations of mineral bodies, and the art of distinguishing and describing them.

"There is no branch of science," says Sir J. Herschel, "which presents so many points of contact with other departments of physical research, and serves as the connecting link between so many distant points of philosophical speculation, as this. To the geologist, the chemist, the optician, the crystallographer, it offers especially the very elements of their knowledge, and a field for many of their most curious and important inquiries; nor, with the exception of chemistry, is there any which has undergone more revolutions, or been exhibited in a greater variety of forms. To the ancients it could scarcely be said to be at all known; and, up to a comparatively recent period, nothing could be more imperfect than its descriptions, or more inartificial and unnatural than its classifications. The more important minerals in the arts, indeed,—those used for economical purposes, and those from which metals were extracted,—had a certain degree of attention paid to them for the sake of their utility and commercial value, and the precious stones for that of ornament; but until their *crystalline forms* were attentively observed, and shown to be determinate characters, on which dependence could be placed, no mineralogist could give any correct account of the real distinction between one mineral and another. It was only, however, when chemical analysis had acquired a certain degree of precision and universal applicability, that the importance of mineralogy as a science began to be recognized, and the connection between the external characters of a stone and its ingredient constituents brought into distinct notice."

In the above quotation, the two characters of minerals upon which their classification is founded are adverted to, namely, their *structure* and their *composition*; and, pursuing these as their leading objects, mineralogists have of late discarded a number of other qualities upon which much stress was formerly laid, but which are so variable and indefinite as to be really of little value; such, for instance, as weight, colour, touch, and other sensible qualities, which often vary in different specimens of the same mineral.

There are so many disadvantages belonging to any mineralogical arrangement founded exclusively on crystalline form, or on chemical composition, that, for all practical purposes, it is necessary to blend the two; but since the chemical theory of definite proportionals, or, as it is commonly called, the atomic theory, has been shown to be applicable to the greater number of mineral combinations, the chemical arrangement of mineral substances has assumed a new and important aspect: it being of course necessary, in describing a mineral, that its crystalline form and modifications should in all cases form an essential part of such description, where at least it can be attained; for it must be recollected that there are many cases in which minerals do not occur crystallized, and where that characteristic, therefore, would be totally at fault. It has been well observed by Dr. Thomson (*System of Chemistry*, Part III., Introduction), "that if mineralogy were to be confined to mere crystallized bodies, it would be divested of the greatest part of its utility; for a very great proportion of those minerals that are of the greatest utility to man, and which, therefore, it is peculiarly important to be able to distinguish from others, are seldom found in the state of regular crystals. How often do the ores of copper, tin, lead, and iron occur in an amorphous state? And were a mineralogist incapable of distinguishing them from each other, and from other minerals, except in the rare cases when they assume a regularly crystallized form, his knowledge would be useless, as far as the important arts of mining and metallurgy are concerned."

Mineralogical analysis, as connected with the atomic theory, has made no inconsiderable progress in the skilful and industrious hands of Berzelius; but it is still quite in its infancy as regards the foundation of a mineral arrangement; and, before it can be successfully adopted as such, many new analyses, and much laborious revision of former researches, will be requisite. One of the latest authors on mineralogy, who has adopted an arrangement founded upon the chemical composition of minerals, is Dr. Thomas Thomson. He divides minerals into three classes: —

Class I. *Acid Bases.* (Those bodies which become acids when combined with oxygen.)

	Species.
Genus I. Carbon	11
II. Boron	1
III. Silicon	7
IV. Phosphorus.	
V. Sulphur	1
VI. Selenium.	
VII. Tellurium	1
VIII. Arsenic	5
IX. Antimony	5
X. Chromium.	
XI. Molybdenum	1
XII. Tungstein.	
XIII. Columbium.	
XIV. Titanium.	
XV. Vanadium.	

Class II. *Alkaline Bases.*

I. Ammonia	2
II. Potassium	1
III. Sodium	7
IV. Lithium.	
V. Barium	5
VI. Strontium	6
VII. Calcium	30
VIII. Magnesium	37
IX. Aluminum.	
1. Pure, or combined with bases	7
2. Simple salts	24
3. Double anhydrous salts	39
4. Double hydrous salts, soluble in water	3
5. Double, insoluble in water, and phosphates	4
6. Double hydrous aluminous silicates, or zeolites	39
7. Triple aluminous salts	15
8. Quadruple aluminous salts	12
X. Glucinum	4
XI. Yttrium	6
XII. Cerium	8
XIII. Zirconium	5
XIV. Thorinum	1
XV. Iron.	
1. Uncombined, or united to a simple substance	13
2. Oxygen salts of iron	22
Double ditto	19
Triple ditto	6
3. Sulphur salts of iron	2
XVI. Manganese.	
1. Combined with simple bodies	11
2. Simple oxygen salts	5
3. Double oxygen salts	5
4. Triple oxygen salts	1
XVII. Nickel.	
1. Combined with simple bodies	5
2. Oxygen salts	1
3. Sulphur salts	2
XVIII. Cobalt.	
1. Combined with simple bodies	5
2. Oxygen salts	2
3. Sulphur salts	1

		Species.
XIX. Zinc.		
	1. United to simple bodies - -	4
	2. Oxygen salts - - -	6
	3. Sulphur salts - - -	1
XX. Lead.		
	1. Native, or united to simple bodies	7
	2. Oxygen salts of lead.	
	a Simple - - -	7
	b Double - - -	10
	c Triple - - -	2
	3. Sulphur salts - - -	5
XXI. Tin - - - - -		2
XXII. Bismuth.		
	1. Native, or combined with simple bodies - - - -	6
	2. Oxygen salts - - -	2
	3. Sulphur salts - - -	1
XXIII. Copper.		
	1. Native, or combined with simple bodies - - - -	6
	2. Oxygen salts - - -	19
	3. Chlorine salts - - -	1
	4. Sulphur salts - - -	5
	5. Selenium salts - - -	1
XXIV. Mercury - - - -		5
XXV. Silver.		
	1. Native, or combined with simple bodies - - - -	10
	2. Oxygen salts - - -	1
	3. Sulphur salts - - -	6
XXVI. Uranium - - - -		5
XXVII. Palladium - - - -		2

Class III. *Neutral Bases.*

I. Gold - - - - -		3
II. Platinum - - - -		1
III. Iridium - - - -		1

We have given the above as a specimen of a chemical mineralogical arrangement; and except, perhaps, that the last class is unnecessarily separated from the preceding, it is sufficiently simple and explicit. The individual characters of each species, such as colour, fracture, hardness, specific gravity, and crystalline forms, constitute, of course, a necessary part of their description.

One of the most useful *practical* works on Mineralogy, and, in our language at least, the most available for the use of the student, is Mr. Allan's edition of the elementary introduction to that science of the late Mr. William Phillips. In this work the following order of arrangement is adopted; and the annexed tables give the distinctive constituents of the respective species.

N. B.—The proportions are indicated by figures, where ascertained; when doubtful, are marked thus —.

EARTHY MINERALS.

Silica.	Silica.					
		Alumina.				
Quartz - -	100					
Opal - - -	—					
Flint - -	98	2				
					Iron.	
Calcedony - -	84	16

MI'NERAL PITCH, *Maltha*. A solid, softish bitumen. Sp. gr. about 1·5.

MI'NERAL TAR. The bituminous substance called *petroleum*. It is brown, viscid, and unctuous. Its specific gravity is 0·88. It is found in Britain, and on the continent of Europe, in the West Indies (Barbadoes tar), and in Persia. It may be resolved by distillation into naphtha and petroleum.

MI'NERAL WATERS. This term is applied to certain spring waters containing so large a proportion of foreign matter as to be unfit for ordinary use.

Mineral waters may, in most cases, be artificially prepared by the skilful application of the knowledge derived from analyses, with such precision as to imitate very closely the native springs. When the various earthy or metallic constituents are held in solution by carbonic acid, or sulphuretted, they should be placed along with their due proportions of water in the receiver of the aerating machine, and then the proper quantity of gas should be injected into the water. Sufficient agitation will be given by the action of the forcing-pump to promote their solution. (See *Ure's Dict. of Arts, &c.*)

The following table shows the composition of several of the principal mineral springs of Europe.

TABULAR VIEW of the Composition of the Principal Mineral Waters of England. One Pint (Wine Measure) contains the following Ingredients: —

Waters.	Gases.			Carbonates.			Sulphates.			Muriates.			Oxide of Iron.	Silica.	Temperature.	Total of Saline Contents.	Authority.
	Nitrogen, C.I.	Carbonic Acid, C.I.	Sulphuretted Hydrogen, C.I.	Carbonate of Soda.	Carbonate of Magnesia.	Carbonate of Lime.	Sulphate of Soda.	Sulphate of Magnesia.	Sulphate of Lime.	Muriate of Soda.	Muriate of Magnesia.	Muriate of Lime.

MI'NERAL YELLOW, or PATENT YELLOW. A compound of oxide and chloride of lead, obtained by digesting powdered litharge in a solution of common salt, washing, drying, and fusing the product. It is used as a pigment.

MINE'RVA. The Latin goddess corresponding to, and confounded with, the Grecian Pallas (Παλλὰς), or Athena (Α'θήνη). She was fabled to have sprung in full armour from the forehead of her father Jupiter. Minerva was worshipped as the goddess of wisdom, and the patroness of industry and the arts. Athens, the city to which she gave name, was her favourite spot; and there her worship was celebrated with great splendour, and the magnificent temple the Parthenon erected to her honour. But she was also worshipped at Rome with peculiar veneration. There she had three temples: one on the Capitol, which she shared with Jupiter and Juno; a second on the Aventine; and a third on the Cælian mount, in which she was worshipped as *Minerva Capta*, an epithet said to have been applied when her statue was transported from Falerii, after the capture of that city by Camillus. At Rome there were also two great festivals celebrated annually in her honour; the one called Quinquatrus or Quinquatria, the other Quinquatria Minora. (See these words.) The origin of the name of Minerva has long puzzled etymologists. Cicero says she is called "Minerva, quia minuit or minatur;" but it has been also fancied that the word is a shortened form of Meminerva (from memini, *I remember*), she being the goddess of memory. It is possibly from the same root as the Lat. mens, *mind*, which is expressed so clearly in many languages wholly unallied, of which the Germ. mann (whence the English *man*), and the Hindostan mena, may serve as examples. But the Tuscan name of the goddess is Menrfa, which seems the immediate source. She was represented as a young woman, with a grave and noble countenance, clothed in armour. *See* PALLAS.

MI'NIATURE. (Fr.) A representation of nature on a very small scale. *Miniature Painting* is generally executed on ivory; and is, as to composition, drawing, and finishing, subject to the same laws as Painting (which see). The outline is traced upon the ivory with a silver point or pencil, and must be extremely light and delicate. This is afterwards drawn in with thin carmine as correctly as possible; the corrections being made with finely powdered pumice-stone, rubbed on with a paper or leather stump. The dead colouring then proceeds, wherein the shadows are left delicate and the lights strong, the full effect being afterwards produced by dotting. The artist usually begins the shades with vermilion and carmine, giving the strongest touches to the most prominent parts, and to those where separations are marked out in shades that are obscure. Indigo is afterwards used for the bluish shades on such parts as recede from the light. Yellow tints, composed of ochre and vermilion, are usually employed on the sides of the nose towards the bottom, under the eyebrows, underneath the cheeks, and on other parts rising towards the light. The backgrounds, if dark, are commonly composed of bistre, umber, or Cologne earth, with black and white; others of a yellow cast by the use of ochre. The grey back-grounds are formed by black, white, and a little indigo. When of a green or olive hue, Dutch pink, white, and black are the ingredients. The back-grounds are formed in two coats, first laying on a light thin tint, and afterwards a darker one of the same colour, evenly and smooth. The dotting is performed by separate dots, or by short notching strokes crossing each other every way so as to have the appearance of being dotted.

MI'NIM. (Lat. minimus.) In Music, a character 𝅗𝅥 equal in duration to two crotchets, or half a semibreve.

MI'NIM. The smallest liquid measure, generally regarded as about equal to one drop. The fluid drachm is divided into sixty minims.

MI'NIMS, or MINIMI, ORDER OF THE. A religious order instituted by St. Francis De Paulo in the fifteenth century. The name is derived from the Lat. minimus, *the least*; by which the founder meant to indicate that humility should be the distinguishing feature of the order. In conformity with this design the rules he prescribed were of the strictest kind. Besides the three usual vows of poverty, continence, and obedience, the most rigid abstinence was inculcated. Except in cases of illness, the members were prohibited not only from touching animal food, but even butter, milk, or cheese, or indeed any kind of sustenance in the composition of

which such materials were used. Their dress was of the coarsest and meanest kind; the colour being black, like that of the Franciscans. Long before the death of its founder, this order had attained so high a degree of celebrity for sanctity that it could boast of monasteries in Italy, France, Spain, and Germany; and at no very distant period it counted no fewer than 450 religious houses scattered throughout Europe and Asia. (See the *Dict. de la Conversation.*)

MINISTER. In Politics, a servant of the sovereign executive power in a state: generally speaking, the head of a department or branch of government. Usage, in different countries, fixes very differently the limits of that higher class of servants to which the term is applied. In the British empire, none but the heads of administrative departments are termed ministers: part of whom belong to the cabinet, and part are not included in it. The cabinet ministers have varied under different administrations; and as our government is of mixed organization, partly to serve the actual necessities of state, and partly retaining ancient distinctions of office founded on usage only, some of the ministers hold merely sinecure appointments. In France, where the forms of government are established more on the principle of utility, there are eight ministers so called: 1. of the interior; 2. of finance; 3. of justice; 4. of public instruction and ecclesiastical affairs; 5. of commerce and public works; 6. of the marine and colonies; 7. of war; 8. of foreign affairs. In England, ministers sit and vote in either house of parliament,—by hereditary right, if peers; as representatives only, if commoners. In France, the same regulation prevails; but ministers have also, by virtue of their office, a right to sit and take part in the debates in either chamber. In the United States, no minister (or secretary, in the language of that government) can be chosen either representative or senator. In some European countries (as Russia), a distinction is established between the private affairs of the sovereign and foreign affairs, on the one hand, which form the combined duties of the cabinet ministers; and the affairs of the interior, which are entrusted to ministers of state. There are also in some governments honorary or *conference* ministers, without any real department of duty. The representatives of minor sovereigns at foreign courts are usually styled *ministers*, instead of *ambassadors*. The term *minister* is also frequently used in a sense synonymous with *clergyman*.

MI'NIUM. (Lat.) In Painting, a red colour, being a calx of lead: according to Pliny it was the common red lead. *See* LEAD.

MI'NNEHÖ'FE. (Germ.; literally *courts of love.*) The name given by the Germans to the cours d'amour, so famous in the history of chivalry. The subjects brought before these courts were chiefly connected with the Romantic gallantry of the period, and consisted either of questions proposed with the view to entrap the judges into some awkward decision; or of serious complaints, resulting from affaires du cœur, which were discussed and decided upon with all the formality of a court of law. These minnehöfe were for a long period looked upon as forming an indispensable part in all chivalrous exercises. Knights, ladies, and poets participated alike in their proceedings; and large collections of their decisions are still extant. A certain number of ladies, remarkable at once for personal and mental attractions, acted as judges in these courts: the fair sex also conducted the proceedings as counsel, attorneys-general, and solicitors-general, &c.; and they were attended by a numerous train of nobles, knights, and others, who were invested by the court with gradations of rank and precedency analogous to those conferred by the sovereign. These courts were held periodically at Signes, Avignon, Lille, and Pierrefeu. The last regular court of this kind was celebrated by Charles VI. and his wife Isabella of Bavaria; but they were now and then renewed at irregular intervals, and the last on record took place as late as the reign of Louis XIV. at Ruelle, at which the princess Maria of Gonzaga presided, and Mademoiselle de Soudey represented the advocate-general. We subjoin a few specimens of the questions proposed in these courts for debate and decision; from which it will be evident that although at the present day there would be little difficulty in deciding upon them, they could not fail at that romantic era to excite considerable discussion. 1. Which is harder to bear,—the infidelity or the death of the beloved? 2. Whether does a man whose wife, or a lover whose betrothed is unfaithful, suffer most? 3. Who is more culpable,—the man who boasts of favours from a lady which he never received, or he who having really received them makes it known? (See the *Damen Lexicon*, Adorf, 1837.)

MI'NNESÆNGERS. The most ancient school of German poets, whose name is derived from the old German word minne (*love*). The songs and fame of the Provençal troubadours appear to have penetrated into Germany under the first emperors of the house of Hohenstauffen; in whose time the crusades and the frequent Italian wars combined to bring their nation, seated as it is in the centre of Europe, in closer communication with those surrounding it. The minnesængers imitated in German the strains of those early poets, and, like them, made love their principal subject; which was celebrated with much of pedantry and false conceits, but, at the same time, not without generous and chivalric feeling. The verses of the minnesængers are in the old Swabian dialect of the high German, which, under the Hohenstauffens, themselves of Swabian race, was the court language. As was the case with the troubadours, the minnesængers belonged to two different classes: there were among them many knights, princes, and even sovereigns; while there was also another class of more professional poets—wandering minstrels, who attached themselves to the persons of distinguished chiefs, or wandered from court to court. The oldest of the minnesængers known to us is Henry of Veldeck, about 1170. During the remainder of the 12th and first half of the 13th century this school of poets flourished; afterwards it gradually declined, and was succeeded by the less chivalrous and homelier school of the master-singers. We possess the names of more than 300 poets, and pieces of the composition of a large proportion of them, who sang during the short period in question. The German amatory poets had their high and low minne, like the celestial and popular Venus of the ancients; the former an abstract and chivalric devotion to a beloved object, the latter a less elevated passion. The ancient German national epic, called the *Niebelungen-Lied*, and the heroic poetry of the *Heldenbuch*, belong to the same period and dialect, and were works of the same race of poets; as were also other poetical romances, founded on the foreign traditions of France, Britanny, and classical antiquity.

MI'NNOW, or MINIM. (Lat. minimus, *least.*) The name of a species of Cyprinoid fish (*Leuciscus phoxinus*, Cuv.), and the smallest of the British species of that family. It inhabits many of the fresh water streams and canals in England, and spawns in June, when each female is attended by two males.

MI'NOR. In Music. *See* MAJOR.

MINO'RITY. In Politics, the period during which the sovereign in an hereditary monarchy is incapacitated from exercising the supreme authority by reason of not having attained the age prescribed by law; also the state of such incapacity. The royal authority, in hereditary monarchies, never dies; and when a sovereign deceases leaving a successor below age, it passes immediately to the person or persons whom the constitution has invested with the authority of regent; as it also does when a king becomes subject to any other incapacity. The term of royal minority is variously regulated by the constitution of different countries. The legal majority of a king of France was fixed at fourteen by an ordinance of Charles V., which has been since followed in that country; but, as a year commenced is reckoned as accomplished, the actual period at which a king of France begins to govern is the age of thirteen years and a day. The same period is fixed by the laws of Spain and Portugal. By the constitution of Great Britain the sovereign is of full age at eighteen years, as far as can be collected from the statutes passed at several times to empower the king to name a regent whenever it has been apprehended that the crown was in danger of devolving on a prince under age.

MINORITY. In Law, the state of an individual of either sex who has not attained the age prescribed by law at which civil rights can be exercised. In England and in France majority is attained on the completion of the 21st year; in Germany on the 25th. The distinctions made by the Roman law between different periods of minority are unknown to our law.

MI'NOR TERM, of a Categorical Syllogism, in Logic, is the subject of the conclusion. The minor premise is that which contains the minor term. In hypothetical syllogisms, the categorical premise is called the minor.

MI'NOS, in Mythological History, was son of Jupiter and Europa, and king of Crete, and so celebrated as a lawgiver on earth that after his death he was appointed judge of the infernal regions, in which office he was associated with Æacus and Rhadamanthus.

MI'NOTAUR. (Gr. Μινως, and ταυρος, *a bull.*) A fabled monster of classical antiquity, half man and half bull, frequently mentioned by the poets. He was said to be the son of Pasiphäe, wife of Minos II. king of Crete, by a bull (ταυρος); hence the term Minotaur. He lived on human flesh; hence Minos shut him up in the famous labyrinth of Dædalus, feeding him with criminals, and afterwards with youths and maidens sent from Athens. As is well known, Theseus, by the assistance of Ariadne, succeeded in destroying him, and thereby rescued the Athenians from the obligation of sending their children to be devoured. The *Dict. de la Conversation* gives an ingenious explanation of this mythological story. See also *Schwenk's Mythologische Andeutungen*, p. 65.

MI'NSTER (Germ.), was anciently applied only to the church of a monastery or convent; and forms the

termination of the name of many places in England in which such churches formerly existed, as Westminster, Leominster, &c. It is sometimes, but incorrectly, used in common language to signify a cathedral church.

MI'NSTRELS. (Fr. minestral, or old Germ. minne, *love*.) Defined by Percy as an order of men in the middle ages who subsisted by the arts of poetry and music, and sang to the harp verses composed by themselves or others. They appear to have been the successors of the minnesængers, scalds, and bards of different European nations, who, even after the age of chivalry had passed, attempted to gain a subsistence by practising those arts which at an earlier period had procured fame and honour for their predecessors. The origin, character, and decline of the minstrels, are thus ably traced in vol. lxxiii. of the *Edin. Review*. In the piping times of peace the minstrel, "*omnis luxuriæ interpres*," as Pliny said of Menander, sang of mimic war to the dull barons of dungeon castles, who had ears, although they could not read — who, doubly steeped in the ennui of wealth and want of occupation, listened greedily, like other great men, to their own praises. Minstrelsy supplied the lack of a more refined intellectual entertainment and of rational conversation, as professional gentlemen do now at civic banquets: their harpings lulled the rude Sauls to sleep, which is now done by quarto epics. The person of the minstrel was sacred; his profession was a passport; he was "high placed in hall a welcome guest:" the assumption of his character became the disguise of lovers of adventure. These advantages raised pseudo-laureates, "idle vagabonds," according to the act of Edward I., "who went about the country under the colour of minstrelsy;" men who cared more about the supper than the song; who, for base lucre, divorced the arts of writing and reciting, and stole other men's thunder. Their social degeneracy may be traced in the dictionary: the chanter of the *gests* of kings, — "gesta ducum regiomque," — dwindled into a "gesticulator," a jester; the honoured joglar of Provence into the mountebank, the juggler, "the jockie," or doggrel balladmonger.

Beggars they are by one consent,
And rogues by act of parliament.

They descended by the usual stages of things of mere fashion: at first the observed of all observers, and therefore then imitated, until they became common — vulgar; which is but one step, and the test at once of merit, universal acceptance, and the forerunner of disgrace: no sooner taken up by the οἱ πολλοι than rejected by the exclusive. In Spain, particularly, this occurred very soon. The really good clergy were shocked at their abuses, while the interested grudged the money earned by rivals who interfered with their monopoly of instructing the people in pious prose, or of amusing them with alexandrine legends. Their Latin synonyme for "scald rhymers" — *scurra mimus*, &c. — will outlive their sculptured caricatures; when mendicant monks, minstrels, fools, monkeys, and beasties are pilloried on pinnacle and gargoyle, in cloister and cathedral. The itinerant monks and mountebanks repaid all this, like Falstaff, by showing up the irregularities of regulars and seculars, "in ballads to be sung to filthy tunes." They undermined their influence. Preachings and songs take part in all national changes; for doctrines precede actions. They were the popular press of the time; opposed by the privileged orders, and watched by statesmen, as Burleigh afterwards employed agents to listen to street songs, — the thermometer of the people's temper. In all these alterations for the worse, the primitive principle "to entertain" remained unchanged. To this the original ballad was sacrificed; passing from one to another, each minstrel begged, borrowed, or stole from all quarters. The originals were corrupted and remodelled; they got their bread by pleasing, — "*magister artis ingenii que largitor venter*." As late as the beginning of last century the houses of many leading families, especially in the northern parts of the empire, were provided with minstrels, who were employed in various duties; all of them, however, in some degree connected with their original occupation. *See* Bard, Scald, Minnesængers, Ballad.

MINT. (Germ. müntze.) The place in which the coin of the realm is manufactured. The whole of the British coin is issued from and manufactured in the Royal Mint in London. The general details of the business of the Mint are briefly stated under the article Coinage.

The Royal Mint received its constitution of superior officers in the 18th year of the reign of Edward II., and continued nearly as then established to carry on its operations within the Tower of London.

Between the years 1810 and 1815 the present magnificent and commodious building was erected on Tower Hill, at the suggestion of a committee of the king's privy council, appointed in 1798 "to take into consideration the state of the coins of the kingdom, and the establishment and constitution of the Mint;" and in 1815 a new constitution was introduced, founded upon a report drawn up by the present Lord Maryborough, who was then master.

The chief officers of the mint are the master, the deputy master, the comptroller, the king's (or queen's) assay masters, the clerk of the papers, and the clerk of the irons and superintendent of machinery: these constitute "the mint board," and meet every Wednesday, or as often as may be required, to transact all the general business of the establishment. The manufacture of the coin is carried on under the direction of the company of moneyers. The other officers are the master's assayer, the melter, the chief engraver, the weigher and teller, the surveyor of the meltings, and the solicitor. The duties of these officers are fully set forth in the "mint indenture." As relates to the general history of the coinage, the reader is referred to the new edition of *Ruding's Annals of the Coinage*. The article "Coinage," in the *Encyclopædia Britannica*, gives an abstract of the duties of the respective officers, and is especially valuable as containing the only extant account, illustrated by engravings, of the machinery employed in the mint: this account, though scanty and imperfect, is tolerably correct. A mass of valuable information, and details respecting the whole establishment, will be found in the *Parliamentary Report of the Select Committee on the Royal Mint*, and its Appendix, published by order of the House of Commons, 30th June, 1837.

Mint. (Lat. mentha.) A name given to several herbaceous aromatic plants belonging to the natural order *Labiatæ*, and genus *Mentha*. Spearmint, or *Mentha viridis*, is that which is so generally used in this country, mixed with vinegar and sugar, as a sauce. Peppermint, or *Mentha piperita*, yields the stimulating oil of the same name. Horsemint and others are also species of the same genus.

MINT, MASTER OF THE. An officer in the English administration, generally removeable with a change of ministry. His salary is 2000*l*. a year. *See* Mint.

MI'NUET. (Fr.) A species of dance performed in slow time and with measured steps, formerly of great celebrity, but now rarely if ever met with.

MI'NUTE. (Lat. minutum.) The sixtieth part of an hour of time, and the sixtieth part of a degree of angular space. In modern astronomical works minutes of time are denoted by the initial letter *m*, and minutes of space by the dash or acute accent, which was first used by Ptolemy.

Minute. In Architecture, the sixtieth part of the diameter of a column; by which subdivision architects measure the smaller parts of an order.

MINUTE GUNS. Guns fired at intervals of a minute, as a signal from a vessel in distress. Also in mourning for great persons.

MI'NUTES. Originally the rough draft of a public instrument drawn up by a notary; so termed because usually written in a smaller character than the instrument itself. The term is now applied to a brief report of the proceedings of a society drawn up by the clerk or secretary: in which sense it is nearly synonymous with *protocol*, which see.

MI'OCENE. (Gr. μειων, *minor*, and καινος, *recent*.) A term applied by Mr. Lyell, in his *Elements of Geology*, to geological formations containing a *minority of fossil shells of recent species*.

MI'QUELETS. In Modern History, a species of partisan troops raised in the north of Spain, and chiefly in Catalonia. The Miquelets became first known in the wars between Spain and France in the 17th century. At several periods (in 1689, 1789, and again in the wars of Napoleon) the French have endeavoured to organize similar corps, to oppose to the Miquelets in the mountain warfare of those districts.

MI'RACLE. (Lat. miror, *I wonder*.) According to the definition of Dr. Johnson, "something beyond human power;" which, though in itself evidently vague and insufficient, may be explained by the addition of "a deviation from the established laws of nature." A miracle must be not only superhuman, but preternatural. Some writers add the "immediate interference of God" as another condition of a miracle; but this assumes a point which is open to controversy, inasmuch as it precludes the agency of evil spirits in such interruptions of the course of nature, which is still a question among theologians. With respect to the credibility of miracles, the most popular argument against them is that of Hume, who considers no weight of particular testimony credible when balanced against our universal experience of the constancy of the laws of nature. "No testimony," he says, "is sufficient to establish a miracle, unless the testimony be of such a kind that its falsehood would be more miraculous than the fact it endeavours to establish." If the words *incredible* or *contrary to experience* be substituted for *miraculous* in this passage, the startling effect of this statement of the argument, in which its efficacy resides, will disappear, and the question will be left upon the very grounds which the believer would choose for his own position. Hume was answered by Dr. Campbell, in his *Dissertation on Miracles*. (See also *Rutherford's Discourse*, 1757; *Douglas's Criterion*;

Locke's Discourse on Miracles; Lardner's Credibility; Middleton's Free Inquiry; Price's Nature of Miracles; some very valuable remarks of Paley, in his *Evidences of Christianity; Hooker's Eccl. Polity*, b. vii. "on Miracles as the Tests of a Supernatural Mission;" *Bentham's Rationale of Evidence.*)

MIRA'GE. (Fr.) An optical illusion very common at sea, and especially in high latitudes, and sometimes also witnessed on land, particularly in Egypt and Persia, and on the margin of rivers and lakes, or on the sea-shore. It arises from unequal refraction in the lower strata of the atmosphere, and causes remote objects to be seen double, as if reflected in a mirror, or to appear as if suspended in the air. When the effect is confined to apparent elevation, the English sailors call it *looming;* when inverted images are formed, the Italians give it the name of *Fata Morgana* (see the term). Ships in the whale fisheries are often descried, and sometimes known, by means of the mirage, at considerable distances. Captain Scoresby recognized his father's ship at the distance of more than 30 miles, and consequently when below the horizon, by its inverted image in the air, though he did not previously know that it was cruising in that part of the fishery. The mathematical theory of the phenomenon is given by Biot, in the *Memoires de l'Institut* for 1809. (See also *Caddington's Optics; Biot's Traité de Physique*, tome iii.; *Brewster's Optics, Cabinet Cyclopedia.*)

MI'RROR. (Fr. miroir.) A speculum or looking-glass, or any other polished body capable of reflecting the images of objects, rays of light from which fall upon them. Silver is considered to be the most powerful reflector; but the speculum metal, as now prepared, is scarcely inferior, if at all so, and in some cases even better. In the very early ages of the world, polished metallic specula were employed as mirrors by the Jewish and Egyptian women, especially of brass; but in modern times, quicksilvered plates of glass are alone used as mirrors.

Concave mirrors are used to concentrate the rays of the sun in a single point, and thereby produce intense heat. The surfaces formed by the revolution of the ellipse, parabola, and hyperbola, are such as reflect them accurately to one point; provided they emanate from one point, are parallel to one another (as the solar rays), or would converge to a more remote point than the one which it is desirable to use. The great difficulty of constructing these has led to the employment of spherical segments, which, though not accurate, yet, under proper restrictions are approximately so. For the mathematical theory, see REFLECTION; see also BURNING GLASS, SPECULUM TELESCOPE.

MIRZA. (A corruption of the Persian title Emir-Zadeh, *sons of the prince.*) The common style of honour in Persia, when it precedes the surname of an individual. When appended to the surname, it signifies prince.

MISA'NTHROPY (Gr. μισος, *hatred*, and ανθρωπος, *a man*), signifies a general dislike or aversion to man and mankind; in contradistinction to *philanthropy*, which means the love of our species.

MI'SCELLANY. (Lat. misceo, *I mix.*) A word usually applied to a collection of literary works or treatises. The most celebrated collection of works known by this name is *Constable's Miscellany.*

MI'SCHNA. The text of the Jewish Talmud, on which the *Gemara*, or second part, is a commentary. It consists of traditions and explanations of scripture. The former are supposed by the Jews to have been delivered to Moses on the mount, and from him to have passed, through the keeping of a succession of prophets and sages, to Rabbi Juda of Tiberias, who committed them to writing. Their compilation is supposed by modern commentators to have taken place about A. C. 150 or 190. (See Prideaux, *Connexion*, vol. ii.; and Lardner, *Collection of Jewish and Heathen Testimonies*, vol. i.)

MISDEMEA'NOR, in Law, is any offence which is the subject of indictment and punishment, not of a felonious character; such are seditious acts, perjury, battery, libels, conspiracies, attempts, and solicitations to commit felonies, &c. Over these offences the justices of the peace at quarter sessions have a general jurisdiction, although they may be removed by certiorari to the King's Bench; and in the trial the defendant has had for a long period of time one remarkable privilege, viz. that his counsel might address the jury, which was equally the case in treason, but not until the year 1837 in any sort of felony. The ordinary punishment of misdemeanors are by fine and imprisonments; sometimes, by statute, transportation. Misdemeanors have been sometimes termed *misprisions;* although this word, in its more restricted signification, is applied to concealments of felony, or treason.

MI'SELTOE, or MISSELTO. A parasitical plant inhabiting the branches of many kinds of trees in the north of Europe. It is the *Viscum album* of botanists. Its connection with Druidical ceremonies is well known; but, as tradition tells us that the priests of that superstition only employed the miseltoe of the oak, some doubt has been entertained of the plant now so called being really that of our ancient chronicles, because it had not been found upon the oak for many centuries. It has, however, been recently discovered upon that tree in the west of England; and this leaves no doubt upon the subject. The powder of the leaves or shoots of the misletoe has been used in epilepsy.

MISERE'RE. The 50th Psalm, 4th of the Penitential Psalms, is that designated by the Roman Catholic church under this word, on account of its first words (in the Vulgate translation, "miserere mei Deus, secundum magnam misericordiam tuam"). It is the usual psalm appointed for acts of penitence and mortification.

MI'SERE'RE MEI. A name given to the iliac passion.

MI'SERICO'RDIA. A narrow-bladed dagger; so termed in the middle ages because it was the weapon used by a knight against a dismounted adversary when he enforced him to cry for mercy.

MISNO'MER. In Law, the description of a person by a wrong name. In grants by deed such mistakes may, in some instances, be corrected by the courts, if the party be sufficiently pointed out in the instrument itself. In grants by will such construction will be more liberally exercised. It is said that the law is not so precise as to surnames as with respect to Christian names. The proper mode for the defendant to avail himself of a misnomer in an action was formerly by plea of abatement; but now the court will amend on motion (3 & 4 W. 4. c. 42.). In criminal cases, the court had the power to amend still earlier (6 G. 4. c. 64.) where the defendant was misnamed. But if the prosecutor be misnamed in an indictment, the variance is fatal, and the defendant must be acquitted. It is to be observed that mere misspelling is no misnomer, if the name have the same sound with the real one.

MISPRI'SION. (From the Fr. mespris, *contempt*, or *negligence.*) In Criminal Law, in its larger sense, it is used to signify every considerable misdemeanor which has not a certain name given to it in the law; and it is said that the offence of misprision is involved in every treason or felony whatsoever. Generally, however, by the word misprision is understood the contempt or neglect, that is, the non-disclosure or concealment, of any treason or felony, committed or to be committed, which a man is cognizant of, but has never assented to; for if he expressly assented, this makes him, in a case of treason, a principal, and, in a case of felony, either a principal or accessory, according to circumstances. Misprision of treason is punished by loss of the profits of lands during life, forfeiture of goods, and imprisonment for life. Misprision of felony in a public officer is punished by imprisonment for a year and a day; in a common person, by imprisonment for a less discretionary time; and in both by fine.

MI'SSAL. The book containing the ritual for the celebration of the various masses of the Roman communion. The missals in use in different churches are not identical in all respects; but the most important part of them, the canon of the mass, as delivered in the Sacramentary of Gregory the Great, which was taken from that of Pope Gelasius in the 5th century, and which is affirmed by Roman Catholics to be a faithful representation of the ritual of the primitive church, is common to all.

MI'SSIONARIES. In ordinary language, ministers who go abroad to preach the gospel to infidel nations. The following table of the present condition of some of the more remarkable missionary societies now existing in England is taken from the *Penny Cyclopedia:*—1. Society for the Propagation of the Gospel in Foreign Parts: receipts, 1837, 43,000*l.*; expenditure, 56,000*l.*; subscribers, about 12,000. This society is conducted on the principles of the Church of England, and was incorporated in 1701, chiefly with a view to our then American possessions. 2. Baptist Missionary Society, founded 1786: receipts, 1837-8, 22,000*l.*; expenditure, 20,000*l.* The operations of this society are chiefly carried on in the East and West Indies. 3. London Missionary Society, founded 1795, now chiefly supported by the Independents: receipts, 1838, 70,000*l.*; expenditure, 77,000*l.* Much connected with the East Indies and the South Seas. 4. Church Missionary Society, founded 1804, "for Africa and the East;" but which has recently sent out missionaries extensively to New Zealand: receipts, 72,000*l.*; expenditure, 91,000*l.* 5. Wesleyan Missionary Society, founded 1817: receipts, 85,000*l.*; expenditure, 100,000*l.* Its most extensive field of labour is in the West Indies. 6. Missions of the Church of Scotland: chiefly India. 7. Missions of the United Brethren, or Moravians, who have been distinguished in this line of exertion since 1731. The Danish missions are among the oldest Protestant; those of the United States are now among the most extensive. The history of Roman Catholic missions in the East is detailed in many works. See *Duhalde*, for China. The rise and fall of Christianity in Japan is narrated by Charlevoix (1715); those in America are slightly noticed in the article immediately following this.

MISSIONS. Stations of missionaries in infidel countries. In Geography, the extensive districts formerly under the control of missionaries of the church of Rome, on the borders of the Spanish and Portuguese settlements in America, were so called. These missionaries chiefly belonged to the orders of the Capuchins, Dominicans, and Jesuits; but the latter were the most celebrated and the most successful. Their settlements in Paraguay comprehended a vast province, which they governed with independent authority: in Brazil they had also extensive districts under their control. The downfal of the order was followed by the destruction of these settlements: those of Paraguay were wholly ruined; those of Brazil, by regulations of the Marquis de Pombal, taken from their spiritual governors and placed on a new footing. The missions of the other orders still continue to subsist on the banks of the Upper Amazon and Orinoco, and in California; but they have undergone severe losses from the revolutionary wars. The success of the experiment of governing the American Indians by missionaries has been the subject of much controversy. It is certain that the Jesuits succeeded better than any other governors have done in rendering them industrious, and subjecting them to discipline. But it is contended that this was only effected by an artificial system, which rendered them the servile and childish dependents of their spiritual masters, and that this slavish state was injurious to them, not only in a moral but a physical point of view, inducing premature decay; insomuch that, it is said, the population of all the missions was continually decreasing, although endeavours were made to keep it up by violent seizures of free natives, who were brought by force within their boundaries. See Charlevoix, *Hist. du Paraguay;* the *Lettres Edifiantes;* Raynal, *Histoire des Indes;* and *Southey's History of Brazil:* the two last writers especially for philosophical views on the subject, although the latter is perhaps too favourable; *Humboldt's Personal Narrative,* for those on the Orinoco; *Forbes's California,* for a very unfavourable view of the condition of those in the latter country. American missionaries have established a government, somewhat similar to those of the Roman Catholic orders, in some of the South Sea Islands. See *Ellis's Polynesian Researches;* the *Voyages* of Capt. Beechey, Capt. Fitzroy, and others.

MITES. A tribe of minute Acaridan Condylopes, which do not suck their food. *See* ACARUS.

MI'THRAS. The grand deity of the Persians, supposed to be the sun or the god of fire, to which they paid adoration as the purest emblem of the divine essence. The Romans also raised altars to the honour of this divinity, with the inscriptions *Deo Soli Mithræ,* or *Soli Deo invicto Mithrae.* As to the introduction of this oriental worship in Rome, see *Mem. de l'Ac. des Inscr.* vol. xvi. p. 270. It was one of those which resisted Christianity the longest. See Beugnot, *Destruction du Paganisme en Occident; Milman's Hist. of Christianity.*

MI'THRIDATE. A celebrated medicinal confection, invented by Damocrates, physician to Mithridates, king of Pontus, and supposed to be an antidote to all effects of poison and contagion; its active ingredient was opium.

MI'TRAL VALVES. The valves of the left ventricle of the *heart.*

MI'TRE. (Gr. μιτρα, *a head band, or diadem.*) The pontifical ornament worn on the head by the pope, cardinals, and in some instances by abbots, in the Roman catholic church, and in the Protestant episcopal church by archbishops and bishops, upon solemn occasions. It appears to have been a hierarchal head covering from the earliest ages of antiquity. Pellerin says, it was that worn by the regal pontiffs of the Hebrews, and, with a few slight modifications, was afterwards adopted by the oriental kings and pagan high priests under the name of *cidaris.* Among the Romans the mitre was originally a sort of head-dress worn by ladies; and Servius makes it a matter of reproach to the Phrygians that they were dressed like women, inasmuch as they wore mitres. There is every reason for supposing that in England the mitre was worn by the bishops on the first introduction of Christianity into the island; and it is supposed in *Gough's Sepulchral Monuments* (vol. i. p. 153.) that the practice was borrowed from the apex or tutulus of the Flamen Dialis in ancient Rome. As an heraldic ornament the mitre of a bishop is surrounded by a fillet set with precious stones: the archbishop's mitre, on the other hand, issues from a ducal coronet.

MITRE. In Architecture, a junction of two pieces of wood or other material at an interior or exterior angle by diagonal fitting.

MI'TTIMUS. (Lat. *we send.*) In Law,—1. a writ for transferring records from one court to another; 2. a precept under the hand and seal of a justice of peace committing an offender to his charge. *See* COMMITMENT.

MIXED CADENCE. In Music. *See* CADENCE.

MIXED FEVER. A fever intermediate between inflammatory and low or typhus fever.

MI'ZZEN MAST. The name given to the mast which supports the after sails, being nearest the stern of the ship.

MNEMO'NICS. (Gr. μνήμη, *memory.*) The art of refreshing the memory of particular things by artificial aids. The common processes of tying a knot in a handkerchief, &c., will exemplify the simplest species of mnemonics, in which we endeavour to connect certain arbitrary acts with peculiar associations, so that the memory of the former may call up the latter. Some persons have taken the precaution, before delivering an address by heart, of entering the room in which it was to be spoken, and connecting in their own minds particular portions of their intended language with certain visible objects in the room. The well-known solemnities observed on the perambulation of parish boundaries, &c., form another instance of practical mnemonics, the object being to fix the memory of particular spots in the mind of those present. For the purpose of facilitating the remembrance of dates, names, &c. various methods have been devised by different writers (especially Feinagle and Gray in England) under the names of Memoria Technica, or Artificial Memory.

MNEMO'SYNE. (Gr. μνημοσυνη.) In Classical Mythology, the goddess of memory: daughter, according to the genealogists, of Uranus (Heaven) and Gaia (Earth), and mother, by Jupiter, of the Nine Muses. Her statues usually have the figure enveloped in long and ample drapery, and the right hand raised towards the chin.

MOAT. A ditch made round the old castles, and filled with water. In some cases this still remains, as at Lickhill Castle; whilst in others they are drained and planted, as at the palace of the Black Prince at Eltham. For the most part, however, all traces of them have disappeared.

The moat surrounding a military fortress of modern construction (or the *ditch*) is left dry; but where it is capable of inundation at pleasure, this circumstance is considered an advantage to the system of defence.

MOBI'LITY. (Lat. moveo, *I move.*) One of the general properties of matter, in virtue of which every body at rest can be put in motion by the action of a force adequate to overcome its inertia. *See* MATTER.

MOCHA STONE. A species of agate.

MO'CKING BIRD. A name given to one of the family of thrushes, the *Turdus polyglottus* of Linnæus, on account of the surprising facility and accuracy with which it can imitate almost any sound; it is also the finest of natural song-birds, and the vocal organs, which are well developed in all the thrush tribe, find their highest perfection and complication in the mocking bird.

This species, in modern ornithological systems, forms the type of a genus (*Mimus* of Boié): it includes other species besides the *M. polyglottus,* all of which are natives of America.

MODE. (Lat. modus.) A term used by Locke to denote "such complex ideas, which, however compounded, contain not in them the supposition of subsisting by themselves, but are considered as dependences on or affections of substances." Of these modes there are two kinds — *simple* and *mixed.* Simple modes are "only variations or different combinations of the same simple idea, without the mixture of any other, as *a dozen* or *a score,* which are nothing but the ideas of so many distinct units added together." *Mixed modes* are those "compounded of simple ideas of several kinds put together to make one complex one, — e. g. *beauty;* and consisting of a certain composition of colour and figure, causing delight in the beholder." It need hardly be said that this distinction is founded on a very imperfect and false analysis. The term is now universally laid aside by writers on mental philosophy.

MODE. In Music, the melodious constitution of the octave, as consisting of seven essential and natural sounds besides the key or fundamental. It is not any single note or sound, but the order of the concinous degrees of an octave, the fundamental note whereof may, in another sense, be called the key, as it signifies the principal note which regulates the rest. The difference between a mode and a key is, that an octave with its natural concinous degrees is called a mode with respect to the manner of dividing it, whilst as regards its place in the scale of music or pitch it is called a key.

MO'DEL. (Lat. modulus.) In Mechanics, a small or miniature representation of the structure of a machine, so as to exhibit its mode of working, &c. Owing to the effect of increased mass in making the machine itself, the results obtained from the model exceed those of the machine in a greater ratio than the linear dimensions of the two works.

MODEL. In the Fine Arts, that which is an object of imitation. In Painting and Sculpture, it is the individual whom the artist procures for getting up his proportions, details, play of the muscles, &c. Also in Sculpture, it is a term applied to the small sketch in wax or clay for a work of art. In Architecture, it is a small pattern in relief, either of wood, plaster, or other material, of the building proposed to be executed.

MO'DELLING. In the Fine Arts, the art of making a mould from which works in plaster are to be cast; also used for the forming in clay of the design itself.

MODERA'TORS, SENIOR and JUNIOR. In the University of Cambridge, two public officers appointed annually to perform various duties. They are ex officio examiners in the senate house. Their name is derived from another of their duties; viz. that of moderating or presiding in the opponemies, or exercises publicly performed in the schools between undergraduates candidates for the degree of bachelor of arts. These disputations, relics of the old university system, are now reduced to little more than matters of form. *Moderator* is also the name applied to the president for the time being of the General Assembly of the Church of Scotland, and of the other inferior church courts, the synods, and presbyteries.

MODI'LLION. (Fr. modillion.) In Architecture, an ornament sometimes square on its profile, and sometimes scroll-shaped, thus , with the intervention of one or two small horizontal members placed at intervals under the corona in the richer orders. They should stand centrally over columns when the latter are employed. They are simplest in the Ionic and Composite orders, more carving being bestowed on them in the Corinthian order. The mutule of the Doric order, which should always stand over the centre of a triglyph, is the same sort of thing, and occupies the same place in the entablature as the modillion.

MO'DULATION. (Lat. modulor.) In Music, the act of moving through the sounds in the harmony of any particular key to those of another; or the transition from one key to another.

MO'DULES. (Lat. modulus.) In Architecture, a measure equal to the semidiameter of a Doric column. It is a term only applied in the Doric order, and consists of thirty minutes.

MO'DULUS. In Analysis, the constant coefficient or multiplier in a function of a variable quantity, by means of which the function is accommodated to a particular system or base. Thus, in the theory of *logarithms*, it is the number by which all the logarithms in one scale of notation must be multiplied to adapt them to the same number in another scale. The only scales or bases actually used in calculation are those of the hyperbolic (or Napierean) and of the common logarithms; and the modulus of conversion is 0·43429448. For *modulus* of elasticity, see ELASTICITY.

MO'DUS (Modus decimandi, or special manner of tithing), in Law, is when lands, tenements, or some certain annual sum or other profit, hath been given time out of mind to a parson and his successors in full satisfaction and discharge of all tithes in kind. It is in some cases a pecuniary compensation, in others compensation in work and labour. *See* TITHES.

MOGRA'BIANS, or MEN OF THE WEST. A name formerly given to a species of Turkish infantry composed of the peasants of the northern parts of Africa, who sought to ameliorate their condition by entering into foreign service.

MOG'UL, GREAT. The name by which the chief of the empire so called, founded in Hindostan by Baber in the 15th century, was known in Europe. The last person to whom this title of right belonged was Shah Allum; and the Mogul empire having terminated at his death in 1806, his vast possessions fell chiefly into the hands of the East India Company.

MOHAIR. (Gr. mohr; Fr. moire; It. moerro; Sp. mue, muer.) The hair of a variety of the common goat, famous for being soft and fine as silk, and of a silvery whiteness. It is not produced any where but in the vicinity of Angora, in Asia Minor. The exportation of this valuable and beautiful article, unless in the shape of yarn, was formerly prohibited; but it may now be exported unspun. The production, preparation, and sale of mohair have long engrossed the principal attention of the inhabitants of Angora; and it used to form an important article of Venetian commerce. It is manufactured into camlets and other expensive stuffs. Hitherto but little has been imported into England.

MOHA'MMEDANISM. One of the most celebrated systems of religion in the world; so called from Mohammed, its author and founder, who was born at Mecca, in Arabia, in May, 571. This founder of a new religion and of a political power, which even in his lifetime extended over his native country, and which under his successors threatened to embrace the empire of the world, traced his genealogy in a direct line through eleven descents from Koreish, the founder of the powerful tribe that bore his name, and who again was affirmed to be in direct descent from Ishmael, the son of Abraham. The future prophet sprung, therefore, from the noblest tribe of the Ishmaelitish Arabs; and his grandfather was at the time of his birth sovereign of Mecca, and guardian of the *Caaba* (which from time immemorial had been identified in the minds of the Arabs with every sacred feeling); consequently, from the sanctity of his territory and his office, a prince of great power and influence. But though descended from so powerful a family, Mohammed's early life was spent in comparative dependence. His father was a younger son of Abdol Motalleb; and having in his early infancy lost both his parents, his only inheritance was five camels and a female slave. On his paternal grandfather was devolved the guardianship of the future prophet; but of this protector he was deprived by death when only eight years of age. In a dying charge Motalleb confided this tender plant of the ancient stock of the Koreish to the hands of Abu Taleb, his eldest son, and the successor of his authority, who amply redeemed the trust reposed in him by continuing throughout life the steadfast friend of his ward amid all the difficulties and dangers to which the latter was exposed in the promulgation of his doctrines. His education, however, is said to have been extremely scanty; and at the early age of thirteen, being intended for a commercial life, he accompanied his uncle's trading caravan into Syria. He afterwards entered into the service of Khadijah, a rich widow of Mecca, to whom his skill in commerce or his other accomplishments so far endeared him that at the end of three years she bestowed upon him her hand and fortune, — an alliance which restored him to the station of his family. At this period he was twenty-five, and his wife forty years of age.

During the first thirteen years of his marriage little or nothing is known of his history; but at the termination of that period he withdrew from society, — resorted to a cave in the neighbourhood of Mecca, where he gave himself up to contemplation, and laid the foundation of that bold and hazardous project which afterwards raised him to glory and dominion. It was in this retirement he gave out that for two years he was in daily communication with the Deity.

In his 40th year he assumed the prophetic office, and displayed his views and principles to his domestic circle. His first convert was Khadijah, whom he always regarded with affection, and even reverence, and whom he placed, after her death, among the only *four* perfect women the world ever saw; the other three being Miriam, the sister of Moses; the Virgin Mary; and Fatima, the youngest of his own daughters. The progress of the new sect was at first very slow. Three years were silently employed in the conversion of fourteen (some say nine) proselytes; but in the fourth year he extended the theatre of his preaching, and proclaimed his doctrines publicly to his fellow-citizens. The faith which, under the name of Islam (*i. e.* salvation), he preached, was compounded substantially of two great principles, which, as Gibbon says, involves an eternal truth and a necessary fiction; namely, that "there is only one God, and that Mohammed is his prophet — the last and greatest of the prophets." He did not, however, aim so much at founding a new religion as reforming the old, as declared by the former prophets, Adam, Noah, Abraham, Moses, and Christ, by putting an end to those superstitions and idolatries by which the true faith had been corrupted. Being urged to confirm the reality of his divine mission by miracles, he wisely declined the attempt, appealing to the internal evidence of his doctrines, and declaring that miracles would depreciate the merit of faith. The only miracle which he professed to have accomplished is a nocturnal journey from Mecca to Jerusalem, and thence through the heavens, on an imaginary animal called Borack, *i. e.* lightning; but the words of the *Koran* are often regarded as figurative and allegorical. He persevered with assiduity in the public exercise of his mission. The citizens of Mecca listened to the exposition of his principles with patience till he attacked the idols of the Caaba. This, however, raised such a storm against him, particularly on the part of the Koreishites, that notwithstanding the protection of Abu Taleb, who, though not converted to Islamism, continued the warm and steadfast protector of his nephew, many of his followers fled to other countries, chiefly to Ethiopia. This happened in the sixth year of his mission, and is called the *first Hegira*, or flight.

In the tenth year of his mission he lost both his wife Khadijah and his uncle Abu Taleb. The death of the latter being the severest blow that the new faith had yet sustained, this year is known in the Mohammedan annals as "the year of mourning." The death of Abu-Taleb removed the only check to the virulent enmity of the Koreishites; and a stranger having succeeded to the sovereignty of Mecca, after a troubled residence of three years, marked, however, by the accession of many proselytes, Mohammed, on the invitation of a deputation from Medina, fled to that city; and instantly, as if by magic, the proscribed and condemned exile became a powerful, and, as it soon appeared, an all but invincible monarch. The flight from Mecca to Medina, which is called the *second Hegira*, or *par excellence* THE HEGIRA, is the epoch from which the Mohammedans date their æra. It occurred in the 53d year of Mohammed's age, and 13th of his mission, and coincides with the 16th July, A. D. 622.

Hitherto Mohammed had used only the mild words of persuasion and argument in propagating his religion. Throughout the eighty-five chapters of the *Koran*, published at Mecca, so far from the use of any species of coercion being recommended to be employed in support of his faith, he exhorts his followers to bear with meekness the injuries to which their principles might expose them, declaring that he had no authority to compel any one to embrace his creed. In the eighteen chapters published at Medina, on the contrary, he taught a very different doctrine, and announced that God had commanded him to extirpate idolatry by force of arms, and to force universal submission to his authority. The enjoyments of paradise were promised to "those who fight for the cause of God, whether they be slain or not." (Sur. 11. 4 9.) Nor were those mere words of course; they were soon reduced to practice. Mohammed, soon after his arrival in Medina, assumed the exercise both of the sacerdotal and regal office. The option of friendship, or submission, or battle, was proposed to the enemies of Islamism. His petty excursions for the defence or attack of a caravan prepared his troops for the conquest of Arabia. But what established his power, and laid the foundation of future conquests, was the issue of the battle of Bedr, near Medina, fought in the second year of the Hegira, between the troops of Abu Sophian, the new sovereign of Mecca, and his own, in which the latter, though only a third of the number of the enemy, gained a complete victory, with the loss of only forty men. From this period the progress of Mohammed, if not a complete triumph (for he sustained some defeats), affords an example of perhaps the most rapid success on record; and at the lapse of six years, in the eighth Hegira, his victorious troops entered the city of Mecca, — an epoch from which may be dated the final establishment of the Mohammedan faith in Arabia. The few contests that followed were merely the last struggles of an expiring opposition, and were mostly terminated by Mohammed's generals; while the prophet himself was employed in destroying the idols enshrined in the Caaba, and in consecrating the temple to the worship of the sole God. The year following is known in Mussulman history as the "year of embassies;" because missions were sent to the prophet from a majority of the Arabian tribes, giving in their adhesion to his creed, and recognizing his authority, both sacred and civil.

But while his religion was thus triumphant, and was destined still farther to spread, and to remain, the prophet's own days were drawing to a close. About three years before his death his health had been declining, in consequence of poison that had been administered to him by a Jewess of Chaibor, in order to test the validity of his divine knowledge. But his death was occasioned by a fever of fourteen days, on the 6th June, 632, in the 10th Hegira, in the 63d year of his age. His remains were buried in Medina, in the very room in which he breathed his last; and though the house itself has long since disappeared, a simple unadorned monument marks the spot where his body reposes. The pilgrim, on his way to Mecca, increases the worth of his pilgrimage if he turn aside to visit also the city which contains the ashes of Mohammed.

During the life of Khadijah, Mohammed did not avail himself of the right of polygamy: after her death, however, the restraints which policy or conjugal affection had imposed on him were laid aside, and the utmost license marked his subsequent career. While he limited the number of wives to four in the case of others, he claimed an exemption to himself on divine authority; and married no fewer than seventeen according to some authorities, and nine according to others: strangely enough, all widows except one, —Ayesha, the daughter of Abu Beker. By Khadijah he had four sons, and as many daughters; and by an Egyptian concubine a fifth son: but his sons all died in infancy; and of ten daughters none survived him except Fatima, who was married to her cousin Ali. From this marriage sprang an illustrious offspring; the ancestors of the numerous existing scherifs, or sons of the prophet.

The religion of the supposititious prophet is contained in the *Koran* (*i. e.* book), the contents of which, according to Mohammedan belief, are uncreated and eternal, subsisting in the essence of the Deity, and inscribed with a pen of light on the table of the everlasting decrees, and communicated at different times to Mohammed by the angel Gabriel. The *Koran*, which is written in the purest Arabic, is, with some exceptions, a work characterized by great richness and sublimity. To the beauty of its style, indeed, its author appeals as a proof of its inspiration; but Gibbon has remarked, that "his loftiest strains must yield to the sublime simplicity of the book of Job" (chap. iv.). Its boldest flights, and its general scope, are borrowed from the sacred volume. Indeed, the object of Mohammed seems to have been to recal the inhabitants of the populous country of Arabia to the worship of the only God, and to unite idolaters, Jews, and Christians in the same creed. He taught that the chain of inspiration was prolonged from Adam to the promulgation of the *Koran;* that Christ did not die on the cross, but that a phantom, or a criminal, was substituted in his place, and that he was translated to the seventh heaven; that Christ rejoiced in the assurance of a future prophet more illustrious than himself; and that the promise of the *Paraclete*, or Holy Ghost, was prefigured in the name, and accomplished in the person, of Mohammed, the last and greatest of the prophets. He taught the existence of angels, good and bad, and of the Devil or *Eblis;* describing the latter as having been expelled from heaven, without hope of recovery, for refusing to pay homage to Adam at the divine command. As to the inspired writings, he acknowledged the Pentateuch, the Psalms, and the Gospel. The doctrine of the resurrection and the day of judgment formed part of his faith. He taught that every man shall be judged according to his works; but that the believers in Islamism shall not be subjected (like the wicked idolaters or infidels) to eternal condemnation, but that, after undergoing a purifying punishment, they shall be translated into the regions of bliss. He inculcated the absolute and unalterable predestination of all things. He called prayer "the pillar of religion," and "the key of Paradise;" and he prescribed five different stated periods of prayer daily, accompanied with as many ablutions or purifications of the body. During prayer he first insisted that the face should be turned to Jerusalem, in compliment to the Jews; but afterwards bestowed that honour on Mecca. Alms, fasting, and pilgrimage to Mecca, are the remaining duties of practical religion enjoined on all good Mussulmans. Of the last the most holy was that of Ramadan, instituted in honour of the month in which Gabriel appeared to him in Mecca. Friday was ordained as the Moslem sabbath, because it was on that day he made his flight to Medina. He continued the rite of circumcision in compliment to the prejudices of his countrymen. He condemned usury, and forbade the drinking of wine.

The grossly sensual character of Mohammed's paradise constitutes, perhaps, the greatest blemish in his religious system, and has exerted a debasing influence over all the countries where it has acquired an ascendency.

To the history of Islamism after the death of its illustrious founder we cannot do more than allude. The rival pretensions of Abu Beker and Ali, the latter of whom called himself "the first believer," to succeed Mohammed in the empire he had founded, both gave a temporary check to the progress of the religion, and produced a schism which exists till the present day. *See* SONNITES, SCHIITES.

Notwithstanding the high pretensions of his competitor, Abu Beker was elected to the office of supreme head of the Mussulman religion and power, under the title of "Caliph," or "Khalif," *i. e.* successor of the prophet. Under his sway, and that of his two immediate successors, the most brilliant success attended the Arab arms. Indeed, by the 20th Hegira, or within ten years of the death of the prophet, Syria, Persia, and Egypt, being conquered, adopted the new faith. Ali was chosen the fourth khalif, but achieved nothing very memorable. At his death, which took place by the hands of an assassin, the throne was usurped by a son of Abu Sophian, whose descendants are called the Omayzade race of khalifs. They held the sovereignty for nearly 100 years; during which time the whole of Africa was overrun, and so far colonized by tribes of Bedouins that it has since remained, as to language, manners, and religion, an Arab country. The Islam faith prospered nearly as rapidly in the East; at least within 80 years from Mohammed's death it embraced all the countries between the Indus and the Atlantic, and from the Indian Ocean to the steppes of Central Asia. It has since penetrated even into China, and found its way into many of the islands in the Indian Archipelago. Spain was taken in 711. The Arabs were, for a short time, masters of the South of France, but were finally driven across the Pyrenees in 732. The Omayzade khalifs were, in the 133d Hegira (A. D. 750), superseded by the descendants of Abbas, one of the uncles of Mohammed. This last dynasty is known in history as that of the Abbasside khalifs.

Meanwhile the seat of the khalifat was removed from Medina to Damascus, and latterly to Bagdad. Nor was the khalifate itself of very long standing. It had been tottering for years; but it fell in the 656th Hegira (A. D. 1258); a Tartar army having taken Bagdad, and put an end to the nominal, sacerdotal, and regal power of the khalifs, the real power having, for a long time, resided in the Turkish sultans of Asia Minor. The title of khalif is now recognized as one of the attributes of the grand segnior as successor of Mohammed, and of the sophi of Persia as successor of Ali; but it no longer implies the discharge of any religious functions.

But neither the foreign conquests of the Mussulmans, nor the downfall of the khalifat, made any essential change in the political state of Arabia. The people adhere to Mohammedanism as the true faith, but otherwise

are divided into petty tribes and communities, as before the birth of the pretended prophet. Of two attempts made in Arabia to reform the Moslem faith; all traces of the first (A. D. 890), the object of which was to rescind the prohibition of wine, and to prevent the pilgrimages to the holy ashes, have disappeared. The other took place in more recent times; namely, in the beginning of last century. It was made by Addul Waheb, who proclaimed himself a prophet sent by God to reform the abuses which gradually had been engrafted on the religion of Mohammed. The chief of the Wahabee doctrines, so called from their author, was, that God was to be worshipped in the strictest unity; and that no adoration should be paid to Mohammed, or any created being. (*See* WAHABEEISM.) But while these doctrines were rapidly spreading, and while the cities of Mecca and Medina had fallen into the hands of the new sect, Mehemet Ali, in the name of the sultan, gave an effectual check (1813) to their farther progress, and restored the holy cities to the nominal authority of the Porte. The Wahabee tenets have since been at a stand, or are on the decline, even in Nedsjed, the native province of the founder. (See *Abulfeda, in vita Mohammed; Prideaux' Life of Mohammed*, 8vo. 1710.; *Adam's Relig. World Displayed; D'Herbelot, Bibliotheque Orient.; Green's Life of Mahomet;* the *Travels* of Niebuhr and others; *Burckhardt's Notes on Bedouins and Wahabees; Rycaut's Present State of the Ottoman Empire; Lives of Mohammed by Boulainvillier and Gagnier; Mill's Hist. of Moham.; Forster's Moham. Unveiled;* and especially *M'Culloch's Geog. Dict.*, art. "Arabia.")

MOIDORE. A Portuguese gold coin, value 27*s*. sterling.

MOI'NEAU. (Fr.) A small flat bastion, raised in front of an intended fortification to defend it from the approaches by means of small arms.

MOIRE'E METALLIQUE, called in this country crystallized tin-plate, is a variegated primrose appearance, produced upon the surface of tin-plate by applying to it in a heated state some dilute nitro-muriatic acid for a few seconds, then washing it with water, drying, and coating it with lacquer. The figures are more or less beautiful and diversified, according to the degree of heat and relative dilution of the acid. This mode of ornamenting tin-plate is much less in vogue now than it was a few years ago. (*Ure's Dict. of Arts, &c.*)

MO'LARS, *Molares*. (Lat. mola, *a mill*.) Teeth generally having a flattened triturating surface, and situated behind the incisors, and laniaries when these are also present. In some Mammals, as the Cape ant-eater, all the teeth are molars. They are generally of two kinds; viz. those which are liable to be displaced and succeeded by others in the vertical direction; and those which are succeeded, and sometimes, as in the elephant and kangaroo, displaced by others developed at the back of the mouth, and advancing forwards horizontally: the first are termed false molars, the second kind true molars.

MOLA'SSE. A provincial name used in Switzerland for a soft green sandstone belonging to the Miocene tertiary period. *See* GEOLOGY.

MOLA'SSES. (Port. melasses.) A brown viscid uncrystallizable sugar. (*See* SUGAR.) It is sometimes used in England in preparing the coarser sort of preserves, and on the Continent extensively in the manufacture of tobacco. It has a burned but not a disagreeable taste.

MOLE. A species of the genus *Talpa* (which see), common in this country and other parts of Europe. This quadruped exhibits in perfection that modification of structure by which the Mammiferous animal is adapted to a subterranean life. Its head is long, conical, and tapering to the snout, which is strengthened by a bone, and by strong gristles worked by powerful muscles. The body is almost cylindrical, thickest behind the head, and gradually diminishes to the tail. There is no outward indication of a neck, that part being enlarged to the size of the chest by the massive muscles which act upon the head and fore-legs. These, which are the principal instruments by which the mole excavates its long and intricate burrows, are the shortest, broadest, and strongest, in proportion to the size of the animal, which are to be met with in the Mammiferous class. The rapidity with which the mole can make its way through a favourable soil is such, that it may be said to swim in the earth; and, since it must displace matter so much denser than water, so do its fore-limbs display a mechanism correspondingly superior in strength to the analogous extremities or pectoral fins of the dolphin. The food of the mole consists of worms and insects: its voracity is great, and it soon perishes if food be scarce or wanting. The ardour of the sexual appetite is not less intense and characteristic of this curious quadruped. The sense of sight is very feeble, the eyes being minute and rudimental; but the other faculties of smell and hearing, as being more serviceable in its dark retreat, are extremely acute.

The female prepares a nest of dry herbage, roots, and leaves, in a chamber commonly formed by excavating and enlarging the point of intersection of three or four passages. The young are brought forth to the number of four or five in April, and sometimes later.

The farmer views the operations of the mole as destructive to his crops by exposing and destroying their roots, or by overthrowing the plants in the construction of the mole-hills; his burrows, moreover, become the haunts and hiding-places of the field-mouse and other noxious animals. The mole is also accused of carrying off quantities of young corn to form its nest. Hence, every means are devised to capture and destroy it, and men gain a livelihood exclusively by this occupation. Some naturalists, however, plead that the injury which it perpetrates is slight, and that it is more than counterbalanced by the benefit which it produces by turning up and lightening the soil, and especially by its immense destruction of earth worms, and many other noxious animals which inhabit the superficial layer of the ground, and occasion great injury to the roots of grass, corn, and many other plants. The soundest practical conclusion lies probably in the mean of these opinions; and the enlightened agriculturist, while he takes prompt measures to prevent the undue increase of the mole, would do well to reflect on the disadvantages which might follow its total extermination.

MOLE. In Engineering, a massive work formed of large stones placed in the sea by means of coffer-dams, extended either in a right line or an arch of a circle before a port, which it serves to close, and to defend the vessels in it from the impetuosity of the waves, &c. It is sometimes used synonymously with *harbour*.

MO'LECULE. (Lat. molecula.) A corpuscle or atom, single or compound. Molecules are the elementary particles into which all bodies are supposed to be resolvable.

MO'LINISM. In Roman Catholic Theology, a system of opinions on the subjects of grace and predestination somewhat resembling that advocated by the Arminian party among Protestants. It derived its name from the Jesuit Louis Molina, professor of theology in the university of Evora in Portugal, who laid down a series of propositions on these debated questions in his work, entitled *Liberi arbitrii cum gratiæ donis, &c, concordia*, which appeared in 1588. He was attacked by the Dominicans on the charge of having advocated in it Pelagian or Semi-Pelagian sentiments, and accused before the Inquisition: he appealed to Rome, and the cause was debated for twenty years in the congregations, and left at last undecided by a decree of Paul V. in 1687. Since that period Molinism has been taught as an opinion which believers are free to embrace in Roman Catholic schools, and generally supported by the Jesuit and attacked by the Jansenist party. It must not be confounded with *Molinosism*, — a name which the doctrine of the Quietists has received from the work of a Spanish enthusiast (Molinos) on Mystical Life, condemned in 1687 by Innocent XI. The French Quietists professed to abjure and oppose the errors of Molinos. (*Mosheim*, 17th Cent. 14. 2. part i.) *See* QUIETISTS.

MO'LISITE. A mineralogical name of the crystallized titaniate of iron of Dauphiny.

MO'LLAH. The title of the higher order of judges in the Turkish empire. After the three first magistrates of the empire (the two cadil-askers of Roumi and Anatolia, and the istambol-cadissy or chief ordinary judge of the capital) follow fourteen mollahs, who preside over the fourteen principal seats of justice in the empire; among these, the mollahs of Mecca and Medina have the highest rank. The place of mollah, like all others in the Turkish empire, is held only at the will of the sovereign, and is now granted annually (see *D'Ohsson, Tableau de l'Empire Ottoman*, vol. iv.); but displaced mollahs preserve their rank in the Ulema above their successors. The Turkish mollah must not be confounded with the Tartar *mulla*, which see.

MO'LLE. (Ital.) In Music, a sound that is flat as com- to another half a tone higher, thence called sharp.

MOLLUSKS, *Mollusca*. (Lat. mollis, *soft*.) The name applied by Cuvier to the great primary division of the animal kingdom which includes all those species having a gangliated nervous system, with the ganglions or medullary masses dispersed more or less irregularly in different parts of the body, which is soft and inarticulate. The pulmonary or branchial circulation is separate and distinct, but is aided by the direct propulsion of a heart in one class only. There is always a heart for the systemic circulation, and it mostly consists of one ventricle and one auricle. Some of the mollusks breathe air, but the greater part respire through the medium of salt or fresh water. The blood of the mollusks is white or blueish. In one class only is there a rudiment of an internal skeleton giving attachment to a part of the muscular system; in the rest it is absent, and the muscles are attached to various points of the skin. Their contractions produce inflexions and extensions of their different parts, and, alternating with relaxations, enable the species to creep, climb, swim, burrow, and seize upon various objects, according as the form of these parts may

permit; but as the locomotive organs are not supported by articulated and solid levers, the mollusks cannot leap or advance rapidly on dry land. Many of the aquatic species are encumbered with a heavy shell. Nearly all the mollusks have an extensive fold of the skin reflected over their body, which it covers like a mantle; it is sometimes produced into a breathing-pipe, or extended and divided in the form of fins. When the mantle is simply membranous or fleshy, or when a horny or testaceous rudiment of a shell is developed, but remains concealed in the substance of the mantle, the mollusk is said to be *naked*. When the shell is so much enlarged that the contracted animal finds shelter beneath or within it, the species is said to be *testaceous*. (*See* CONCHOLOGY.) The masticatory or oral organs present all the various modifications for predatory, omnivorous, or herbivorous habits; and the stomach may be simple, multiple, or complicated with a peculiar armature. Some of the mollusks are unisexual, others androgynous, a few diœcious.

With few exceptions, their habits and economy present comparatively little variety or interest, and they are only preserved by their fecundity and vital tenacity. *See* MALACOLOGY.

MO'LOCH. The name of the chief God of the Phœnicians, frequently mentioned in Scripture as the God of the Ammonites, and probably the same as the Saturn of the Syrians and Carthaginians. Human sacrifices were offered at the shrine of this divinity; and it was chiefly in the valley of Tophet, to the east of Jerusalem, that this brutal idolatry was perpetrated. Solomon built a temple to Moloch upon the Mount of Olives, and Manasseh long after imitated his impiety by making his son pass through the fire kindled in honour of this horrid king.

Milton has described the character of Moloch in the following well-known lines: —

First Moloch, horrid king, besmear'd with blood
Of human sacrifice and parents' tears;
Though for the noise of drums and timbrels loud
Their children's cries unheard, that passed through fire
To his grim idol. Him the Ammonite
Worshipt in Rabba and her watery plain,
In Argob and in Basan, to the stream
Of utmost Arnon. Nor content with such
Audacious neighbourhood, the wisest heart
Of Solomon he led by fraud to build
His temple right against the temple of God,
On that opprobrious hill; and made his grove
The pleasant valley of Hinnom, Tophet thence
And black Gehenna call'd, the type of Hell.

MOLO'SSUS. In Greek and Latin poetry, a foot consisting of three long syllables, as χαιρόντων, *regnabant*. It is said to derive its name either from a favourite dance of the Molossi, a people of Epirus; or from Jupiter Molossus, in whose honour odes were composed in which this foot had a great share.

MOLYBDE'NUM. (Gr. μολυβδος, *lead*.) This name was originally applied to the native sulphuret of molybdenum, which was considered to be an ore of lead; it was afterwards shown to be the ore of a peculiar metal, to which the name molybdenum was given. It is white, brittle, very infusible, and of a specific gravity about 8·6. It forms two oxides and an acid. The equivalent of the metal is about 48; and the *molybdic acid* consists of 1 atom of molybdenum and 3 of oxygen, and is represented by the equivalent 72. The compounds of this acid are called *molybdates*. The molybdate of lead has been found native.

MO'MENT. (Lat. movere, *to move*.) A small but indefinite period of time. Sometimes the word *instant* is used synonymously with moment.

MOMENT, MOMENTUM. These terms have been used by writers on mechanics, in various senses. Galileo, in his *Dialogues*, uses the phrase *momentum of a power*, or *of a weight*, applied to a machine, to denote the action, energy, or impetus of the power to move the machine; so that an equilibrium subsists between two powers when their moments to move the machine in opposite directions are equal: and he shows that the *momentum* is proportional to the power multiplied into the virtual velocity. This notion of momentum was also adopted by Wallis, in his *Mechanics*, published in 1669; and when the term is used with respect to a weight, it is synonymous with the phrase *quantity of motion*, that is, the product of the mass by the velocity.

The product of the mass by the *square* of the velocity, or the *living force* (*see* FORCE), is sometimes called the *moment of the moving force*, or the *moment of activity;* and the product of the mass by the velocity and by a line (or, which is the same, by the square of the velocity and by a time) is called the *moment of the quantity of motion*, or *quantity of action*. (Carnot, *Principes de l'Equilibre et du Mouvement*.)

Modern writers use the phrase *moment of a force with respect to a point*, to denote the product of the force into the perpendicular let fall from the point upon the line of its direction; and *moment of a force with respect to a plane*, to denote the product of the force into the perpendicular drawn from its point of application to the plane. These two moments are entirely distinct. The first depends upon the direction of the force, and is independent of its point of application; the latter depends upon the point of application, and is independent of the direction. (See Poisson, *Traité de Mécanique*.)

MOMENT OF INERTIA, in Dynamics, denotes the sum of the products of all the material elements of a revolving body, each multiplied into the square of its distance from the axis of rotation. It is the integral of the expression $\int r^2\,dm$; in which dm is the element of the mass, and r its distance from the axis. *See* ROTATION.

MO'MIERS. (From the Fr. momerie, Ang. *mummery*.) The name by which certain religionists of the so-called Evangelical party have been designated in Switzerland, and some parts of France and Germany, since 1818. They appear originally to have borne a considerable resemblance to the Methodists of our own country; for, like the latter, they at first embraced no tenets distinct from those of the established church, and were only distinguished from its members by a more habitual indulgence in devotional contemplation and religious exercises. But they did not long continue to harmonize with the preachers of the establishment. One of the most vehement of the party, in a pamphlet published in 1818, accused the latter of denying the divinity of our Saviour, and of a thorough backsliding from the doctrines of Calvinism; and the Geneva clergy (*la venerable compagnie*) having, in the view of allaying asperities, passed a resolution prohibiting any theories of the doctrinal points of religion from being propounded in the pulpit, and having counselled the clergy to avoid disputed points as much as possible in their discourses, the smouldering embers of their hostility to the established church burst into a flame. They now began to attack the clergy in the pulpit and in pamphlets, accusing them of having abandoned all gospel truth, and denying their right to be regarded as ministers of the establishment. But all their efforts to bring the latter into contempt were unsuccessful: the Genevese remained faithful to their pastors; and in the year 1835 the Momiers possessed only about 200 adherents.

In other parts of Switzerland, however, and more especially in the canton de Vaud, the zeal of these sectaries was attended with more success. After a few years' toleration of their preaching and proselytizing, during which it was alleged the Momiers had sown the greatest discord and discontent among the inhabitants of the canton, the government at last saw the necessity of interference; and in the year 1824 promulgated some vigorous ordinances to put them down. These enactments, as might have been expected, failed of their effect. The enthusiasm of the Momiers was redoubled: they were now surrounded with the glory of martyrdom; and many who before had viewed their zeal with indifference or contempt now deeply sympathized in what they could not but regard as an undisguised attack upon the liberty of conscience. In consequence of the general disgust that ensued on their promulgation, these ordinances were at first gradually relaxed, then suffered to lie dormant, and at last repealed in 1831. Since that period the number of the Momiers has gradually diminished; and in 1839 the clergy of this canton resolved by a large majority to revert to the ancient *regime* of the church. (See the *Conversations Lexicon der Gegenwart*. See also the *Edin. Review*, vol. xlii., which contains an interesting account of the rigorous enactments passed against this sect, with some severe remarks on their violence and absurdity.)

MO'MUS. (Gr. μῶμος, *derision*.) The god of raillery and ridicule, and said by Hesiod to have been the progeny of light.

MO'NACHISM, MONK, MONASTERY. (All derived from the Gr. μόνος, *alone*.) Words indicative of certain important features in ecclesiastical history. Monachus, or monk, properly signifies one who lives a solitary life, and was applied in the first instance to the numerous individuals who began in the second and third centuries to retire from the occupations of the world, and devote themselves in the deserts of Egypt and Syria to a contemplative and religious life. It was not till the middle of the third century that the monkish system, properly so called, was established, by which many persons were congregated together, and bound by vows to the performance of various religious duties and abstinence from wordly enjoyments. These monks are distinguished by the appellation of Cænobites, or Associates, from the ascetics, anchorites, and hermits, who lived apart not from the world only, but from each other. The monkish system originated in Egypt, where St. Anthony founded several associations of this kind. The inmates of the primitive monasteries were bound by the profession of four objects: solitude, labour, fasting, and prayers. They renounced all temporal possessions, and supported themselves entirely with their own hands. Fasting was practised in moderation only; nor do the early monks appear to have affected piety or regularity by the extravagant austerities of later times. For an useful list of books on the subject, see this article in the *Penny Cyclopædia*.

For an account of the progress of this practice, and the

rules to which the professors of Monachism were subjected in later times, see ORDERS (RELIGIOUS).

MO'NAD. (Gr. *μονας, an unit.*) In Metaphysics, this word has been used by Leibnitz and his followers, partisans of what has been called the Monadic Theory. "After studying," says Stewart, "with all possible diligence, what Leibnitz has said of his *monads* in different parts of his works, I find myself quite incompetent to annex any precise idea to the word as he employed it." He then quotes the following as "some of his most intelligible attempts to explain his meaning:"—"A simple substance has no parts: a compound substance is an aggregate of simple substances, or of monads." "Monads, having no parts, are neither extended, figured, nor divisible. They are the real atoms of nature; in other words, the elements of things." "Every monad is a living mirror, representing the universe, according to its particular point of view, and subject to no regular laws, as the universe itself." "Every monad with a particular body makes a living substance." (*Enc. Brit.*, Preliminary Dissertation, note c. c.) The groundwork of the monadic theory is to be found in the different philosophical systems of Zeno, Leucippus, Democritus, and Epicurus; but Leibnitz was the first who reduced it to a system, and its chief supporters since his death have been M. Wolf and Madame Duchâtelet.

MONADE'LPHONS. (Gr. *μονος*, and *αδελφια, a fraternity.*) A botanical term applied to stamens the filaments of which are combined into a single mass, as in the common mallow. It is the name of some of the classes in the Linnæan system.

MONA'NDROUS (Gr. *μονος*, and *ανηρ, a man*), is a flower having but one stamen. It is the name of the first class in the Linnæan system.

MO'NARCHY. (Gr. *μοναρχία;* derived from *μόνος, single*, and *ἄρχειν, to rule.*) The government of a single person. Monarch and monarchy are equivalent in common speech to king and kingdom; so that we often read of the Spartan monarchs, &c., although the government of Sparta was under a double race of kings reigning at the same time. Monarchies are usually said to be of four kinds,—*absolute*, *limited*, *hereditary*, and *elective*, which are self-explanatory terms. The only elective monarchy in Europe was that of Poland. All absolute and limited monarchies have adopted the hereditary principle.

MO'NAS. (Gr. *μονας.*) A genus of extremely minute polygastric Infusores.

MO'NASTERY. (Gr. *μονος.*) The general name for those religious houses appropriated to the reception and maintenance of monks and nuns, but especially of the former. (*See* NUNNERY.) For an account of the origin and object of monasteries, see MONACHISM, and the authorities there referred to; and for the habits, rules, and peculiarities of the different orders of monks and nuns, see the respective articles, but more especially ORDERS, RELIGIOUS. The English term *monastery* was variously rendered by the Greek fathers; thus we find it expressed not only by *μοναστηριον* and *μονη*, but by *σεμνειον, a holy place, μανδρα, an inclosure, φροντιστηριον, a place of meditation*, &c. The suppression of monasteries was one of the first consequences of the Reformation in all the countries that abandoned the Popish faith. But even in Roman Catholic states, with the exception of Italy, they have long been on the decline; and though since the relaxation of the penal laws several nunneries have been established in various parts of Great Britain, there is no reason to suppose that these establishments will ever attain even an approximation to their pristine vigour.

MO'NDAY. The second day of the week is so called, and means, literally, the *day of the moon*. Its equivalents in Fr. and Germ. are respectively Lundi and Montag, signifying also *day of the moon*.

MO'NEY.* In Political Economy, the name given to the commodity adopted to serve as the *marchandise bannale*, or universal equivalent of all other commodities; and for which individuals readily exchange their surplus products or services.

Without the use of money of some sort or other exchanges must have been greatly embarrassed, and the division of employments never could have been carried to any considerable extent. Innumerable difficulties would occur in attempting to carry on trade by barter. A., for example, has a quantity of corn which he wishes to exchange for cloth belonging to B.; but the latter being already sufficiently supplied with corn, no exchange can take place between them. A. must therefore, if he continue anxious to get possession of the cloth, learn what commodity B. will accept in exchange for it; and having learned this, he must seek out some third person willing to part with the equivalent demanded by B. in exchange for corn. It might not, perhaps, be possible for A. to get his purpose effected so easily as has here been supposed, or without negotiating several subsidiary exchanges; but what has now been stated is sufficient to evince the extreme difficulty of carrying on commerce in this way.

Individuals so placed would naturally endeavour, in seeking their own advantage, to obviate, in as far as practicable, such inconveniences; and it would require but little sagacity to perceive that the best way of accomplishing this would be to acquire some portion of that article, whatever it might be, which was observed to be most in demand, or which passed most readily from hand to hand in exchange for others; because, when possessed of it, one would be able, with comparatively little difficulty, to get whatever else he wanted. Now, this generally desirable article, whether it be corn, salt, cowries, hides, or whatever else, is in fact money. But though this grand instrument of exchange may be one thing in one country and one state of society, and another thing in another country and another state of society, it is never the result of invention or contrivance. It originates in the circumstances natural to society; and is changed, improved, and perfected, according as experience serves to make individuals better acquainted with its nature and functions.

An article that has been adopted from a sense of its suitableness to serve as the ordinary equivalent for other things, or as the common medium of exchange, comes in the course of time to be used also as a *measure of value*, or as a standard by which to compare and estimate the values of other things. Thus, instead of saying that an individual is worth 1000 sheep, 1000 quarters of wheat, or 1000 acres of land, these are rated or estimated at their value in money; and it is said that their owners are worth certain amounts of the latter. Not only, therefore, does the introduction of money contribute in the most effectual manner to the facilitating of exchanges, but it also gives precision to statements as to values that would otherwise be all but unintelligible. The statement, for example, that an individual was worth 1000 head of cattle, or 1000 packs of wool, would convey no clear idea even to dealers in these articles, as their qualities differ so very widely; and supposing these to be ascertained, there are very few individuals who know anything of the value either of cattle or wool. But by rating them in money, all these difficulties and ambiguities vanish in an instant; reference is then made to a measure with which every body is familiar, and every one has a distinct idea and full knowledge of the value of the articles, or wealth of the parties referred to.

Qualities required in a Commodity fitted to serve as Money.—An immense variety of commodities have been adopted to serve as money in different countries and states of society; but, in the course of no very long period, it is ascertained that no commodity can be advantageously employed as money unless it possess certain properties. First, it should be easy of transportation, and, therefore, should possess great value in small bulk: 2d, it should admit of being rubbed and carried about without losing much from the wear, and it should admit of being hoarded or kept for an indefinite period without loss: 3d, as the products to be exchanged for money are of very different value, it should also admit of being divided into the smallest portions without injury: 4th, the commodity used as money should be perfectly homogenous; that is, a given quantity of money in London should be precisely identical with the same quantity in Edinburgh, Dublin, and every where else: and, 5th, the value of money or its power of exchanging for or buying other things should be as invariable as possible, or should change only by slow degrees. These seem to be the qualities most essential to any commodity adopted to serve as money; and the money of any country may be said to be good or bad according to the degree in which it possesses or wants these qualities.

Now, it will be found that the precious metals possess all the qualities enumerated above in a far higher degree than any other products with which we are acquainted; and this has doubtless formed the irresistible reason that has led all civilized communities to adopt them as money. The cost of their production, especially of gold, is so very considerable that they possess great value in small bulk; their firm and compact texture makes them difficult to wear, and they may be kept for any length of time without deteriorating; they are divisible into any number of parts, and have the valuable property of being easily reunited by means of fusion without loss; they are perfectly identical, the physical qualities of an ounce of pure gold or silver taken from the mines in any part of the world being precisely the same with those of an ounce taken from the mines in any other quarter; and though their value be not invariable, it changes, speaking generally, only by slow degrees, and is less susceptible of fluctuation than that of most other articles. No wonder, therefore, when almost all the qualities necessary to constitute money are possessed in so eminent a

* Etymologists differ respecting the derivation of the word money. Some contend that it comes from monere (*to admonish, to inform*), because the stamp impressed on coins indicates their weight and fineness. Others contend that it originates in the circumstance of silver being originally coined at Rome, in the temple of admonishing Juno, or *Juno Moneta.*

degree by the precious metals, that they have been used as such in civilized societies from a very remote æra. They became universally money, to use the words of Mr. Turgot, "not in consequence of any arbitrary agreement among men, or of the intervention of any law, but by the nature and force of things."

Introduction of Coined Money.—When first brought to market, gold and silver, like copper, iron, or any other metal, were in the shape of bars or ingots; and were exchanged or bartered for other commodities exactly as these would have been bartered for anything else. The parties having agreed upon the quantity of the precious metals to be given for certain goods, the quantity was next delivered by weight. Nor is this a mere conjectural statement, advanced in a later age to explain appearances, and resting on probability only. Aristotle (*Polit.* lib. i. cap. 9.) and Pliny (*Hist. Nat.* lib. xxxiii. cap. 3.) tell us that such was, in fact, the method by which the precious metals were originally exchanged for other things in Greece and Italy; and the sacred writings furnish a striking example of the prevalence of the same primitive practice in the East. It is there stated that Abraham weighed 400 shekels of silver, and gave them in exchange for a piece of ground he had purchased from the sons of Heth. (Genesis, xxiii. 16.) It is also mentioned that this silver was "current money with the merchant," an expression which evidently refers to its quality only; for, had the silver been coined, it would have been unnecessary to have weighed it. But the weighing of gold and silver whenever they happened to be exchanged for commodities, and their adjustment to the agreed on weight, must have been a very difficult and troublesome process. There can, however, be no doubt that the greatest obstacle to the use of the precious metals as money would, at first, be found in the difficulty of determining their purity or fineness with sufficient facility and accuracy. It is, indeed, most probable that when they originally began to be used as money their quality would be inferred from their weight and colour. But the extreme inexactness of the conclusions derived from such loose and unsatisfactory data would soon become obvious; and the devising of some method by which the weighing of the metals in exchanges might be dispensed with, and their quality be easily and accurately determined, would be seen to be indispensable to their general use as money. Luckily such a method was not long a desideratum. It was early discovered that to ascertain its purity, and to obviate the trouble and expense of weighing the metal, all that was necessary was to form it into *coins;* that is, to mark each piece with a public stamp or authoritative impress declaring its weight and fineness. Such appear to have been the steps that led to the formation and introduction of gold and silver coins (*Goguet*, *De l'Origine des Loix*, i. 269. 4to ed.); the employment of which has been of the very greatest utility, and has perhaps contributed more than anything else to facilitate commerce, and to accelerate the progress of civilization and the arts.*

"Without some article of known exchangeable value, such as coin, readily received as an equivalent for other things, the interchange of commodities must have been very limited, and consequently the divisions of labour very imperfectly established. Now money obviates these evils, and by a twofold operation augments production. In the first place, it saves all that time and labour which, while the intercourse between man and man is carried on by barter, must frequently intervene before a person can be supplied with the quantity of the commodity which he wants; in the second place, and in consequence of its saving the time and labour which must otherwise be spent in effecting exchanges, it multiplies the transactions of mercantile industry, and thus allows the divisions of employment to be more thoroughly established. By the first operation it disengages a very considerable portion of labour from an unproductive occupation, and enables it to receive a more useful direction; by the second it increases in a very high degree the productive powers of the labour already usefully employed. It assists every man in availing himself of the skill and dexterity which he may have acquired in any particular calling, and promotes cultivation in a manner suitable to the climate and soil of different districts and different countries. And by both these operations coins increase to an extent, not easy to be calculated, the wealth of civilized communities." (*Torrens on the Production of Wealth*, p. 305.)

But, however great and obvious the advantages attending the use of the precious metals in the shape of coin, it is necessary to bear in mind that the nature of exchanges, and the principle on which they are made, are not thereby at all affected. Equivalents are still given for equivalents. The exchange of a quarter of corn for an ounce of pure unfashioned gold bullion is as much a barter as if it were exchanged for an ox, or a barrel of beer; and, supposing the metal to be formed into a coin, or marked with a stamp declaring its weight and fineness, that circumstance could, it is obvious, make no change in the terms of the barter. The coinage would save the trouble of weighing and assaying the bullion, but it would do nothing more. A coin is merely a piece of metal of a known weight and fineness, and the commodities exchanged for it are uniformly held by the parties to be of equal value; and yet these obvious considerations have been very generally overlooked. The notion was long entertained that coins were merely the *signs* of values! But it is clear that they have no more claim to this designation than bars of iron or copper, sacks of wheat, or any other article. Coins exchange for other things because they are desirable articles, which having been produced by an expenditure of capital and labour, possess real intrinsic worth. A draft, cheque, or bill may not improperly, perhaps, be regarded as the sign of the money or coin to be given for it; but that coin is itself a valuable commodity. A sovereign is not a sign,—it is the thing signified.

Privilege of Coining. Legal Tender.—In order to obviate the endless confusion and inconvenience that could not fail to arise were individuals permitted to coin money, from the circulation of coins of all weights and degrees of purity, the government of every civilized country has prohibited the issue of coins by private parties, and has itself supplied those in circulation. Generally, also, very severe penalties have been inflicted on the forgers of coin, or on those who fabricate counterfeit coins, or coins of less weight than the standard, or made up in whole or in part of some baser or less valuable metal. It is obvious, indeed, that the extensive practice of this offence, by necessarily generating a feeling of insecurity and suspicion, would check the circulation even of genuine coins, and would consequently in so far deprive society of the advantages resulting from their employment. It is found, however, that the improvement of the fabric of the coins, by the perfecting of the dyes and otherwise, is a more effectual means than even the utmost severity of punishment for the prevention of forgery; though some very considerable degree of the latter is, of course, always indispensable.

Where the use of coins has once been adopted, all values in contracts and other engagements are rated or estimated in money; and it is usual in almost all countries to enact that coins of the legal or standard weight and purity shall be *legal tender*, and to declare that no legal proceedings of any kind shall be instituted on account of any debt or pecuniary obligation against any individual who has offered to liquidate the same by payment of an equivalent amount of the recognized coin of the country. A pound troy, or 12 oz. of the metal of which English silver coins are made, contains 11 oz. 2 dwts. pure silver, and 18 dwts. alloy. This pound is coined into 66 shillings; so that each shilling contains 80·727 grains fine silver, and 87·27 grains standard silver; and the money pound, consisting of 20 shillings, contains 1614·545 grains pure silver, and 1745·454 grains standard silver. From 1600 down to 1816, the pound weight of standard silver bullion was coined into 62 shillings. All the English silver coins have been coined out of silver of 11 oz. 2 dwts. fine, from the Conquest to this moment, except for the short period of sixteen years from the 34th Henry VIII. to the 2d Elizabeth.

The fineness of gold is estimated by carat grains equivalent to $2\frac{1}{2}$ dwts. troy; gold of the highest degree of fineness, or pure, being said to be 24 carats fine. The purity of our present gold coins is 11 parts fine gold and one part alloy. The sovereign, or twenty-shilling piece, contains 113·001 grains fine gold, and 123·274 grains standard gold. The pound troy of standard gold is coined into 46 sovereigns and $\frac{89}{120}$ths of a sovereign, or into 46*l.* 14*s.* 6*d.* The mint or standard price of gold is therefore said to be 46*l.* 14*s.* 6*d.* per pound troy, or 3*l.* 17*s.* $10\frac{1}{2}$*d.* an ounce. The alloy in coins is reckoned of no value; it is allowed in order to save the trouble and expense that would be incurred in refining the metals to their highest degree of purity, and because when its quantity is small it renders the coins harder, and less liable to be worn or rubbed. Were the quantity of alloy considerable, it would lessen the splendour and ductility of the metals, and would add too much to the weight of the coins.

Before the art of metallurgy was well understood, the baser metals were frequently used as money. Iron was the primitive money of the Lacedæmonians, and copper of the Romans. But both iron and copper deteriorate by being kept; and, besides this defect, the rapid improvement of the arts, by lowering their price, rendered their bulk too great in proportion to their value to permit of their continuing to be used as money. Copper, indeed,

* The Roman jurists have given a clear and concise account of the circumstances that led to the use of money, and of its functions:—"*Origo emendi vendendique a permutationibus cœpit: Olim enim non itd erat nummus; neque aliud merx, aliud pretium vocabatur; sed unusquisque, secundum necessitatem temporum ac rerum, utilibus inutilia permutabat, quandò plerumque evenit ut quod alteri superest alteri desit. Sed quia non semper, nec facile concurrebat, ut cum tu haberes quod ego desiderarem, invicem haberem quod tu accipere velles, electa materia est, cujus publica ac perpetua æstimatio difficultatibus permutationum æqualitate quantitatis subveniret; eaque materia formâ publicâ percussa, usum dominiumque, non tam ex substantia præbet quam ex quantitate; nec ultra merx utrumque, sed alterum pretium vocatur.*" (*Digest*, lib. xviii. tit. I. de Contr. Empt.)

is still used in the form of tokens, convertible into silver in very small payments. In this country, copper pence and halfpence are rated at about 72 per cent. above their real value; but as their issue is exclusively in the hands of government, and as they are only legal tender to the extent of *one shilling* in any one payment, this overvaluation is not productive of any bad effect. The use of copper in other countries is limited in much the same way; gold and silver being every where the only metals made use of in the manufacture of the coins used in considerable payments.

Variations of the Standard. — The value of all sorts of property being estimated, and the stipulations in almost all contracts for its purchase, sale, or hire being made in money or coins, it is plain that no change can take place in the value of such money or coins without virtually subverting these estimates and contracts, and enriching the debtor portion of society at the expense of the creditor portion, or *vice versâ*. As the cost of producing all commodities is liable to vary from improvements in the arts, the exhaustion of the present or the discovery of new sources of supply, none can be selected to serve as money or coin that may not vary in its *cost* or real value. It is believed, however, that the precious metals vary less than any material that could be suggested; and, with the exception of the extraordinary fall in their value caused by the discovery of the American mines, it seems to have been remarkably constant at other periods.

But, in addition to the fluctuations naturally inherent in the value of coins, arising from variations in the cost of the metal of which they are made, their standard has been repeatedly changed. Notwithstanding that money or coin, from its being universally used as a scale by which to compute the value of all commodities, and as the equivalent for which they are commonly exchanged, is by far the most important of all the measures used in society, and should, consequently, be preserved as invariable as possible, there is none that has been so frequently altered. The necessities or extravagance of governments have forced them to borrow; and, to relieve themselves of the incumbrances thus contracted, they have almost universally had recourse to the disgraceful expedient of degrading the coin; that is, of *cheating* those who lent them money to the extent of the degradation, and of enabling every other debtor in their dominions to do the same.

The ignorance of the public in remote ages facilitated this species of fraud. Had the names of the coins been changed when the quantity of metal contained in them was diminished, there would have been no room for misapprehension. But, although the weight of the coins was undergoing perpetual and their purity occasional reductions, their ancient denominations were almost uniformly preserved; and the people who saw the same names still remaining after the substance was diminished, — who saw coins of a certain weight and fineness circulate under the names of florins, livres, dollars, and pounds, — and who saw them continue to circulate as such after both their weight and the degree of their fineness had been lessened, began to think that they derived their value more from the *stamp* affixed to them by authority of government than from the quantity of the precious metals they contained. This was long a very prevalent opinion; but the rise of prices which invariably followed every reduction of the standard, and the derangement that was thereby occasioned in every pecuniary transaction, undeceived the public, and taught them and their rulers the expediency of preserving the standard of money inviolate.

The standard may be reduced by simply raising the denomination of the coin; by ordering, for example, that a half-sovereign should pass for a sovereign, and the latter for a double sovereign, &c. If injustice be resolved upon, this is the least mischievous way in which it can be perpetrated, inasmuch as it saves all the trouble and expense of a recoinage. But as it renders the fraud obvious and glaring, it has rarely been resorted to; and most reductions have been effected either by diminishing the weight of the coins, or by increasing the proportion of alloy in the metal of which they are made, or both.

Originally the coins of all countries seem to have had the same denominations as the weights commonly used in them, and contained the exact quantity of the precious metals indicated by their name. Thus, the *talent* was a weight used in the earliest period by the Greeks, the *as* or *pondo* by the Romans, the *livre* by the French, and the *pound* by the English and Scotch; and the coins originally in use in Greece, Italy, France, and England bore the same names, and weighed precisely a talent, a pondo, a livre, and a pound. The standard has not, however, been preserved inviolate, either in modern or ancient times. It has been less degraded in England than any where else; but even here the quantity of silver in a pound sterling is less than the *third* part of a pound weight, the quantity it contained in 1300. In France, the livre current in 1789 contained less than *one sixty-sixth* part of the silver implied in its name, and which it had actually contained previously to 1103. In Spain and some other countries, the degradation has been carried still further.

From 1296 to 1355 the coins of England and Scotland were of the same weight and purity; but at the last-mentioned epoch the standard of Scotch money was, for the first time, sunk below that of England; and by successive degradations the value of Scotch money, at the union of the crowns in 1600, was only a *twelfth* part of the value of the English money of the same denomination. It remained at this point till the union of the kingdoms cancelled the separate coinage of Scotland.

The gold and silver coins of Ireland have been for a considerable period the same as those of Great Britain; but until 1825 they were nominally rated $8\frac{1}{3}$ per cent. higher. This difference of valuation, which was attended with considerable inconveniences, was put an end to by the act 6 Geo. 4. c. 79., which assimilated the currency throughout the empire.

Mint or Government Valuation of Gold and Silver Coins. — If both gold and silver coins be made legal tender, it is obviously indispensable that their value with respect to each other should be fixed by authority; or that it should be declared that individuals shall be entitled to discharge the claims upon them by payments either of gold or silver coins, according to some regulated proportion, — a practice which was long adopted in England.

But the value of each of the precious metals is liable to perpetual changes; and hence, how accurately soever their proportional value, as fixed by the mint regulations, may correspond with the proportion which they actually bear to each other in the market when the regulation is made, the chances are ten to one that it will speedily cease to express their relation to each other. The moment, however, that such a change takes place, it becomes the obvious interest of every one who has a payment to make to make it in the *overvalued* metal; which, consequently, becomes the sole, or nearly the sole, currency of the country. Hence the reason why the coins of some countries are almost wholly of silver, and others almost wholly of gold. It is estimated, for example, that when it was fixed, in 1717, that the guinea should exchange for 21 shillings, gold was overvalued as compared with silver to the extent of $1\frac{19}{31}$ per cent. (*Liverpool on Coins*, p. 85.); and as the real value of silver with respect to gold continued to increase during the greater part of last century, the advantage of paying in gold in preference to silver became more decided, and ultimately led to the universal use of gold in all large payments, and to the fusion or exportation of all silver coins of full weight. (*Liverpool, loco cit.*)

In France a different valuation of the metals has had a different effect. Previously to the recoinage in 1785, the *Louis d'or* was rated in the mint proportion at only 24 livres, when it was really worth 25 livres 10 sols. Those, therefore, who should have discharged the obligations they had contracted by payments of gold coin instead of silver, would plainly have lost 1 livre 10 sols on every sum of 24 livres. In consequence very few such payments were made; gold was almost entirely banished from circulation, and silver became almost the only species of metallic money used in France. (*Say, Traité d'Economie Politique*, tom. i. p. 393.)

In 1816 a new system was adopted in this country; it being then enacted (56 Geo. 3. c. 68.), *that gold coins only should be legal tender in all payments of more than* 40 *shillings*. The pound of silver bullion that had previously been coined into 62 shillings was then also coined into 66 shillings, the additional *four* shillings being retained by government as a *seignorage* or duty (amounting to $6\frac{14}{31}$ per cent.) upon the coinage. To prevent the silver coins from becoming redundant, government has retained the power to issue them in its own hands. Under these regulations, silver has ceased to be a standard of value, and forms merely a subordinate or subsidiary species of currency, or change, occupying the same place in relation to gold that copper occupies in relation to itself. This system has been found to answer exceedingly well.

A good deal of difference of opinion has existed as to whether gold or silver coins are best fitted for being made a legal tender. It does not seem that the one possesses any very striking advantage over the other; none, certainly, that would justify a change, after a selection has been made and acted upon for any considerable period.

Down to 1626, a seignorage or duty upon the coinage was usually charged upon the gold and silver coins issued by the mint; and it may be easily shown that the imposition of such a duty, when it is not carried to an undue height, is advantageous. A coin is more useful than a piece of uncoined bullion of the same weight and purity; the coinage fitting it for being used as money, while it does not unfit it for being used for any other purpose. When, therefore, a duty or seignorage is laid upon coin equal to the expense of coinage, it circulates at its real value; but when this charge is defrayed by the public, it circulates at *less* than its real value, and is consequently

either melted down or exported whenever there is any demand for bullion in the arts, or any fall in the exchange. It is, indeed true that were a seignorage to be laid on gold coins, it would be necessary, to prevent an enhancement of the value of the currency, that their weight should be proportionally reduced; and it is on this account better, perhaps, to let them remain on the present footing. But when a seignorage was laid on the silver coins, in 1816, it was not necessary to take the circumstance now alluded to into consideration; for as they were made subordinate to gold, and were intended to serve as change merely, its imposition had no tendency to raise the value of the currency, at the same time that it was calculated effectually to prevent the fusion of the coins, and to yield a small revenue to government.

The exportation and importation of gold and silver coins was formerly prohibited; but in 1819 it was enacted (59 Geo. 3. c. 49.), that they might be freely exported and imported, without being liable to any charge or duty whatever; and they may be imported without being either reported or entered at the custom-house. This regulation has rendered it next to impossible to ascertain the value of the bullion imported.

Paper Money. — But, how great soever the advantages resulting from the employment of gold and silver as money, we are not to suppose that these are obtained gratuitously. The use of a metallic currency is accompanied by a heavy expense; and there is a much greater difficulty in effecting payments by the agency of coins than one might, at first, be disposed to believe. If the currency of the United Kingdom consisted wholly of gold, it would certainly amount to at least 60 millions sterling; the expense of which, allowing ¼th per cent. for the wear and tear and loss of coins, could hardly be estimated at less than *three* millions a year. But this heavy expense is really a far less serious obstacle to the exclusive use of the precious metals as money than their weight, and the trouble and expense attending the carrying them about. The weight of 1000 sovereigns exceeds 21 lbs. troy; so that it would be necessary to employ a waggon to make a large payment even in gold. It is also very difficult to employ it in the making of small payments, provided they have to be made at any considerable distance, inasmuch as the expense of sending gold by post, and the premium to guarantee it against loss, amount to a considerable sum. Hence it is that all commercial nations endeavour to fabricate a portion of their money of some less valuable and more portable material than bullion; and hence also the origin of bills of exchange, cheques, and other devices for economising the use of money.

Of the substitutes that have been resorted to instead of gold and silver coins, *paper notes*, payable on demand, have been by far the most generally adopted, and are in all respects the most eligible. Intrinsically they are almost destitute of value, so that their employment and their loss costs next to nothing *; and they may be carried about or transmitted by post with the utmost facility. But though in these respects the employment of pieces of paper instead of coins leaves nothing to be desired, it is plain that having no value in themselves their value must depend entirely on artificial means or regulations. They are commonly issued as a substitute for or representative of coin, the issuer being bound to pay their value, or the sums they profess to represent, in coin of the standard weight and purity, the moment it is demanded; and so long as this regulation is really and *bonâ fide* complied with, no inconvenience can result from their employment. Practically, however, it is found no easy matter to carry these regulations into effect; and this, and indeed every country in which paper money has been issued, has repeatedly sustained the greatest injury from its being issued in excess or on unsound principles. Paper money, in fact, can never be either securely or beneficially employed, unless the quantity of it in circulation vary exactly as the quantity of gold or silver coins to be substituted in its stead would do were it withdrawn. But having elsewhere inquired into the means by which this identity between the value of coins and paper notes may be best maintained, we beg to refer the reader to the article BANKS in this Dictionary for a farther discussion of this important branch of the subject.

I. ENGLISH COINS. — Account of the English Silver and Gold Coins; showing their Value, the Seignorage or Profit upon the Coinage, and the Price of the Pound Troy of Standard Gold and Silver, from the Conquest to the present Time.

* The loss of a note is no doubt as severely felt by the holder as the loss of an equivalent amount of coin; but as the issuer of the note is benefitted by its loss to the same extent that the holder is injured, the society is plainly neither the better nor the worse for the occurrence.

† 1527 — Henry VIII.] The Saxon or Tower pound was used at the mint up to this time, when the pound troy was substituted in its stead. The Tower pound was but 11 oz. 5 dwts. troy; so that, from the Conquest to the 28 Edward I., 20 shillings in tale were exactly a pound in weight.

‡ 1666 — 18 Charles II.] The seignorage on the coinage was at this time given up, and the gold bullion brought to the mint has ever since been coined free of expense. A seignorage of $6\frac{14}{31}$ per cent. was imposed on the coinage of silver by 56 Geo. 3.

II. Account of the Contents or Weight, and of the Value in Sterling, of the principal Gold Coins of different Countries.

Gulden of the Dutch E. I. Co. (1820)	148·4	1	8·72

Ancient Coins. — We subjoin, for the convenience of such of our readers as may have occasion to consult works in which reference is made to ancient coins, the following tables of those that were principally current among the Jews, Greeks, and Romans. They were calculated by Dr. Arbuthnot (*Tables of Ancient Coins, Weights, &c.*, 4to ed. Lond. 1754), and do not differ materially from the tables of Paucton, whose *Métrologie* (4to, Paris, 1780) is the most complete and elaborate work that has ever been published with respect to ancient monies, weights, and measures. At the same time we confess we should not be disposed to place much reliance on these tables, and we have elsewhere stated our reasons for holding this opinion. — (Art. "Money," New Edit. *Encyc. Britannica.*)

* This value of the American eagle is taken from average assays of the coins of twelve years.

† This is the coin which is universally circulated under the name of the Spanish dollar.

Jewish Coins.

Names and Proportions.					Value in Sterling. L.	s.	d.
Gerah					0	0	$1\frac{59}{160}$
10	Bekah				0	1	$1\frac{11}{16}$
20	2	Shekel			0	2	$3\frac{3}{8}$
1,200	120	50	Maneh, Mina Hebraica		5	14	$0\frac{3}{4}$
60,000	6,000	3,000	60	Talent	342	3	9
Solidus aureus, or sextula, worth					0	12	$0\frac{1}{2}$
Sicius aureus, worth					1	16	6
A talent of gold, worth					5475	0	0

Grecian Coins.

											s.	d.	qrs.
Lepton											0	0	$0\frac{31}{336}$
7	Chalcus										0	0	$0\frac{31}{48}$
14	2	Dichalcus									0	0	$1\frac{7}{24}$
28	4	2	Hemiobolum								0	0	$2\frac{7}{12}$
56	8	4	2	Obolus							0	1	$1\frac{1}{6}$
112	16	8	4	2	Diobolum						0	2	$2\frac{1}{3}$
224	32	16	8	4	2	Tetrobolum					0	5	$0\frac{2}{3}$
336	48	24	12	6	3	$1\frac{1}{2}$	Drachma				0	7	3
662	96	48	24	12	6	3	2	Didrachma			1	3	2
1,324	112	96	48	24	12	6	4	2	Tetradrachma		2	7	0
1,660	384	120	60	30	15	$7\frac{1}{2}$	5	$2\frac{1}{2}$	$1\frac{1}{4}$	Pentadrachma	3	2	3

Of these, the drachma and didrachma were of silver; the rest, for the most part, of brass.

The drachma is here, with the generality of authors, supposed equal to the denarius: though there is reason to believe that the drachma was somewhat the weightier.

	Value in Sterling. L.	s.	d.
The Grecian gold coin was the stater aureus, weighing 2 Attic drachms, or half of the stater argenteus; and exchanging usually for 25 Attic drachmas of silver	0	16	$1\frac{3}{4}$
But according to our proportion of gold to silver it was worth	1	0	9
There were likewise the stater Cyzicenus, exchanging for 28 Attic drachmas, or	0	18	1
The stater Philippicus, and stater Alexandrinus, were of the same value.			
Stater Daricus, according to Josephus, worth 50 Attic drachmas, or	1	12	$3\frac{1}{2}$
Stater Crœsius, of the same value.			

Value and Proportion of the Roman Coins.

						Sterling. s.	d.	qrs.
Teruncius						0	0	$0\frac{775}{1000}$
2	Sembella					0	0	$1\frac{55}{106}$
4	2	Libella, As				0	0	$3\frac{1}{10}$
10	5	$2\frac{1}{2}$	Sestertius			0	1	$3\frac{3}{4}$
20	10	5	2	Quinarius, Victoriatus		0	3	$3\frac{1}{2}$
40	20	10	4	2	Denarius	0	7	3

	L.	s.	d.
The Roman gold coin, or aureus, weighed generally double the denarius; its value, according to the proportion of gold to silver mentioned by Pliny, was	1	4	$3\frac{3}{4}$
According to the proportion that now obtains amongst us	1	0	9
According to the decuple proportion mentioned by Livy and Julius Pollux	0	12	11
According to the proportion mentioned by Tacitus, by which the aureus exchanged for 25 denarii, its value	0	16	$1\frac{3}{4}$

MO'NEYERS, COMPANY OF. This company, which is of very ancient origin, are officers of the Royal Mint, under whose superintendence and responsibility the various moneys of the realm are manufactured. They receive the bars of standard metal from the *melter*, and under their direction these are rolled down, cut into blanks, and coined: these processes are described under the word COINAGE. The connection of the Company of Moneyers with the other officers of the mint will be evident from the duties of the other officers, which are stated under the word MINT. (See also Mr. Atkinson's account of the origin and constitution of the Company of Moneyers, in the Parliamentary Report of the Select Committee on the Royal Mint, 1837, p. 119.)

MONOCA'RPONS (Gr. μονος, *single*, and καρπος *fruit*), is a term invented by De Candolle to designate what gardeners call annual plants, and a few others which, like the American aloe, although they may live for many years, yet perish as soon as they have once borne fruit.

MO'NOCHORD. (Gr. μονος, and χορδη, *string*.) In Music, an instrument consisting of a single string stretched between two bridges standing on a graduated rule, for the purpose of measuring the variety and proportion of musical sounds. The monochord is called the harmonical canon, or the canonical rule.

MONOCHROMA'TIC LAMP. When a solution of common salt is added to spirit of wine, the mixture burns with a flame in which yellow predominates almost to the exclusion of the other coloured rays; the consequence is, that objects viewed by this light are all either yellow or black, and deficient in the tints which they exhibit when seen by solar light, or by that of our ordinary combustibles. (See Sir David Brewster, in the volume of the *Family Library* on "Natural Magic.") The term *Monochromatic* is of the same origin as —

MO'NOCHROME. (Gr. μονος, and χρωμα, *colour*.) A painting executed in a single colour. *See* PAINTING.

MO'NOCOTYLE'DONS. (Gr. μονος, and κοτυληδων, *a lobe*.) A class of plants having but one cotyledon or seed-lobe in the embryo. They are now more generally called *Endogens*, which see.

MO'NODELPHS, *Monodelphi*. (Gr. μονος, and δελφυς, *a womb*.) A name given by De Blainville to the first sub-class in his binary division of Mammalia, comprehending those which have no supplementary external pouch or marsupium, but which bring forth the young in a state sufficiently mature not to require such additional protection. It is antithetical to *Didelphs*.

MO'NODON. (Gr. μονος, and οδους, *a tooth*.) The generic name of the narwhal, signifying its supposed peculiarity of having but one tooth, which projects like a horn from the fore-part of the head; a second tooth, however, is always to be found concealed in the adjoining jaw, where it remains in a rudimental state. In the female both tusks are rudimental.

MO'NODY. (Gr. μόνος, and ᾠδη, *a song*.) A species of poem of a mournful character, in which a single mourner is supposed to bewail himself: thus distinguished from those pastoral elegies (like the *Daphnis* of Virgil) which are in the form of dialogues.

MONŒ'CIA. (Gr. μονος, and οικος, *a house*.) In Botany, the twenty-first class in the system of Linnæus, comprising the Androgynous plants, or those whose structure is both male and female.

MO'NOGRAM. (Gr. μονος, and γράμμα, *letter*, or *writing*.) An abbreviation of a name by means of a cipher composed of two or more letters intertwined with each other. Monograms were used on coins in very ancient times, being found on Greek medals of the age of Philip and Alexander of Macedon. The Greek monogram of the name of Christ, which resembles P placed perpendicularly in the middle of an X, thus ☧, is found on coins of the age of Constantine. By far the greater number of the ancient monograms are still unintelligible; though the labour and research which have been expended in endeavouring to decipher their meaning have in many instances been rewarded with success. Among others whose researches on the ancient monograms may be consulted with advantage are, Montfaucon, *Palæographia Græca*; Froelich, *Annal. Reg. Syr.*; Combe, *Museum Hunterianum*; Torremuzza, *Description des Monnaies de Sicile*; Pellerin, *Recueil des Villes, des Peuples, et des Rois*; Mionnet, *Traité de la Numismatique*. Monograms are frequently found on coins and maps of the middle ages; and they are also to be met with as a substitute for the signature of the princes of that period. This class of monograms is of great importance in illustrating the monuments of antiquity, and their investigation constitutes a distinct and peculiar branch of diplomatics. In later times monograms were frequently employed by printers and engravers to record their names at the end or on the title-page of a book, or in some portion of an engraving. A great deal of attention has likewise been bestowed upon this branch of monogrammatic writing, and with considerably more success. The Abbé de Marolles, in 1667, was the first who directed attention to this subject; and to him succeeded Florent Lecomte (*Cabinet des Singularités d'Architecture, &c.*); Orlandi (*Abecedario Pittorico*); Fr. Chrüt (*Anzeige und Auslegung der Monogrammatum*); De Virloy (*Dictionnaire d'Architecture*); and Bartsch (*Peintregraveur*, a work of great accuracy and research). But the most complete and accurate information on this class of monograms is to be found in the *editio optima* of Brulliot (*Dictionnaire des Monogrammes, &c., avec lesquels les Peintres, &c., ont designé leurs Noms*, 2 tom. 4to. Munich, 1832; a work which is founded on the principle of considering

the *first* letter of the monogram as the key to its explanation.

A monogram is said to be *perfect* when it contains all the letters of the word it is intended to represent. (*Dict. de la Conversation, &c.*)

MO'NOGRAPH (Gr. μονος, and γραφω, *I write.*) A treatise or memoir on a single subject of a limited description. Such, for example, are the greater part of the memoirs which are read before learned societies.

MONOGY'NIA. (Gr. μονος, and γυνη, *a female.*) In Botany, the name given by Linnæus in his system to the first order or subdivision in each of the first thirteen classes of plants, comprising such as have one pistil or stigma only in a flower.

MO'NOLITH. (Fr. monolithe; from Gr. μονος, and λιθος, *a stone.*) A term recently introduced into England, to signify a pillar or other large substance consisting of a single stone. Herodotus speaks of a huge rock of this sort in front of the temple of Minerva at Sais, which was scooped out, and contained an apartment 18 cubits in length, 12 in breadth, and 5 in height. It was said to have been transported from the town of Elephantine by order of king Amasis, and to have occupied 3000 men for three years in conveying it. Some remarkable monoliths have been found in Egypt; of these the zodiac of Denderah, and the obelisk of the Luxor, both of which have been removed to Paris, are well-known examples.

MO'NOLOGUE (Gr. μονος, and λογος, *a discourse*), or SOLILOQUY (Lat. solus, *alone*, and loquor, *I speak*), is, as its name imports, a speech uttered by one of the dramatis personæ of a play when alone, or, as it is vulgarly termed, speaking to himself. The introduction of the soliloquy is obviously a very unnatural contrivance in the dramatic art; yet its obvious necessity reconciles the spectator to it. In the drama of ancient Greece soliloquies are rare; for the passages at the commencement, or "prologues" of plays, where the first actor comes forward and explains his own character and something of the subject of the piece to the audience, can hardly be termed soliloquies. The speech of Ajax before his death is a celebrated exception.

MO'NOMA'NIA. (Gr. μονος, and μαινομαι, *I rage.*) Insanity upon one particular subject, the mind being in a sound state in reference to other matters.

MO'NOME, or MONOMIAL. (Gr. μονος, and νομη, *a part.*) In Algebra, an expression composed of a single term, or a series of factors, all which are single terms.

MONOME'RANS, *Monomera.* (Gr. μονος, and μηρος, *a limb.*) A section of Coleopterous insects, including those in which the tarsi were supposed to be formed of a single joint.

MO'NOMY'ARIES, *Monomyariæ.* (Gr. μονος, and μυων, *muscle.*) All those bivalves or conchifers which have only one adductor muscle, and consequently but one muscular impression on each valve.

MONONEU'RANS, *Mononeura.* (Gr. μονος; νευρον, *nerve.*) A term applied by Rudolphi to the series or primary division comprehending the animals which he believed to have only the ganglionic system of nerves, as the Mollusks and Insects.

MONOPE'TALOUS (Gr. μονος, and πεταλον, *a petal*), in Botany, is applied to a corolla, the petals of which cohere by their contiguous margins, so as to form a tube.

MONOPHY'LLUS (Gr. μονος, and φυλλον, *a leaf*), in Botany, is applied to a calyx the sepals of which cohere by their contiguous edges into a kind of tube or cup.

MONO'PHYSITES. (Gr. μονος, and φυσις, *nature.*) A name given in the 5th century to certain heretics who, in the language of the Athanasian creed, "confounded the substance," that is, the divine and human substance, which are united in Christ, but neither absorbed into the other. *See* INCARNATION, EUTYCHIANS, NESTORIANS. (Mosheim, *Eccl. Hist.* vol. ii.)

MO'NOPLEU'ROBRA'NCHIANS. (Gr. μονος, and πλευρα, *a side*, βραγχία, *gills.*) A name given by De Blainville to an order of his class *Paracephalophora*, comprehending those species which leave the branchiæ more or less completely covered by a part of the mantle, and situated on the right side of the body.

MONO'POLY (Gr. μονος, and πωλεω, *I sell*), in Law, is defined by Sir E. Coke (3 *Inst.* 181. c. 5.) "an institution or allowance by the king, by his grant, commission, or otherwise, to any person or persons, bodies politic and corporate, of or for the sole buying, selling, making, working, or using of any thing, whereby any person or persons, bodies politic or corporate, are sought to be restrained of any freedom or liberty that they had before, or hindered in their lawful trade." The practice of granting monopolies, giving to one or a few individuals the sole privilege of producing, importing, or dealing in certain articles, has been acted on to a greater or less extent in all countries, and was carried to an oppressive and ruinous extent in England in the reign of Elizabeth and the earlier part of that of James I. At length the grievance became quite insupportable; and notwithstanding the strenuous opposition of the crown, it was finally abolished by the famous statute of the 21 Jas. 1. cap. 3. Its provisions did not extend to patents for new inventions, nor to grants by act of parliament to corporations, &c. But it suppressed all private monopolies; and by giving full freedom to industry and invention, contributed more perhaps to accelerate the progress of improvement than any other act in the statute book.

MONOPO'LYLOGUE. (Gr. μονος, πολυς, *many*, and λογος, *a discourse.*) A term recently invented to designate an entertainment in which a single actor sustains many characters.

MONO'PTERAL. (Gr. μονος, and πτερον, *a wing.*) In Architecture, a temple or circular enclosure of columns without a cell.

MO'NORHYME. (Gr. μονος, and ῥυθμος, *measure.*) A composition in verse, in which all the lines end with the same rhyme. This species of composition is said to owe its invention to Benin, who wrote in Latin, and dedicated his monorhymes to Pope Alexander III.

MONO'STOMA. (Gr. μονος, and στομα, *a mouth.*) The name of a genus of Trematode Entozoa, including those which have only a single pore, serving at once for nutrition and adhesion.

MONOTHA'LAMANS. (Gr. μονος, and θαλαμος, *a chamber.*) This term is applied to those univalve shells which have only one chamber.

MO'NOTHEISM. (Gr. μονος, and θεος, *a god.*) The doctrine of, or the belief in, the existence of one God; in contradistinction to Polytheism, the belief in a plurality of Gods. The Jewish, Christian, and Mohammedan systems of religion are the only pure specimens of Monotheism in existence. It has often been supposed that the Jews alone, of all the nations of antiquity, had conceived the truth of there being only one God; but there can be little doubt that there are no well-founded reasons for this opinion. In the arcane theology of Egypt, not only was the unity of the Deity acknowledged, but he was even adored, not as the God of any particular religion, but as the eternal and omnipotent Governor of the Universe. In support of this assertion the testimony of various heathen writers might be cited; but the following passage from Jablonski may supersede the necessity of adducing any other authority. "Those men," he observes, "who were most distinguished for wisdom among the Egyptians, acknowledged God to be a certain unbegotten Eternal Spirit, prior to all things which exist; who created, preserves, contains, pervades, and vivifies everything; who is the Spirit of the Universe, but the Guardian and Protector of men." That many of the priests and poets and philosophers of Greece were not ignorant of the same truth, is not less evident. In one of the *Orphic Fragments*, preserved by Proclus, we find it expressly declared, that "there is One Power, One Deity, the great Governor of all things." The verses which, according to Bishop Warburton, were sung in the Eleusinian Mysteries, contained the following passage: — "Pursue thy path rightly, and contemplate the King of the world: He is One, and of himself alone, and to that One all things have owed their being. He encompasses them. No mortal hath beheld him; but he sees everything." In some verses which have been often cited by the fathers from a tragedy now lost, Sophocles has said, "There is in reality only One God, who made the heavens and the remote earth, the blue waves of the ocean and the strength of the winds." That Pythagoras admitted the unity of the Deity must be evident to all who have considered his philosophy; and his monotheism is further attested not only by the eclectic philosophy, but in distinct terms by St. Justin and St. Cyril. Euclid of Megara and Socrates were both Monotheists: Plato was in all probability one likewise. His Trinity, like that of the Magi and the Egyptians, was not a trinity of beings, but of modes of being in the Divine Nature. "When," says he, "I speak fairly in my epistles, I commence with *God;* — when I do not, my letters begin with *gods.*" But if any further proof were wanting in support of this opinion, the following passage from Origen must be held to be conclusive: — "Many of the old philosophers have said that there is one God, who created all things; and in this they agree with the law: but some say in addition, that God hath made and governs all things by his Word; and that it is the Word of God by which all things are regulated. In this they write consonantly not only with the law, but with the Gospel." (*Edin. Review*, vol. vii. pp. 97, 98.)

MONO'THELITES (Gr. μονος, and θελω, *I will.*) A sect of heretics, who, while they avoided the error of the Eutychians, and allowed the two natures of Christ to coexist distinctly in the unity of the person, conceived the influence of the divine will so to predominate over the human substance as to leave to the latter no action or efficiency of its own.

The origin of this doctrine is ascribed to the emperor Heraclius, who, in the year 630, attempted to reconcile the Eutychians or Monophysites to the Catholic church by a middle course of this nature, and published an edict under the advice of some theologians of the day in assertion of it. This opinion was condemned by some provincial and one general council; and, on the other

hand, was maintained by the edict of several succeeding emperors. Nor was the question finally settled, though silence was frequently commanded upon it, until it was forgotten in the louder disputes of the Iconoclasts and their opponents. (Combefils, *Monothelit. Hist.*, 2 tom. 1648.)

MONO'TONY. (Gr. μονος, and τονος, *a sound.*) An irksome sameness either in speaking or composition.

MONOTRE'MES, *Monotrema.* (Gr. μονος, and τρημα, *a hole.*) A tribe of ovo-viviparous Mammalia, of which only two genera are known to exist; viz. the *Platypus* or *Ornithorhynchus*, and the *Echidna*, both peculiar to Australia. The term is indicative of the common cloacal outlet for the excremental and generative products.

MO'NOTRI'GLYPH. (Gr. μονος, and τριγλυπτος, *thrice cut.*) In Architecture, such an intercolumniation in the Doric order as brings only one triglyph over it.

MONSEIG'NEUR. A title of courtesy in France, which was prefixed to the titles of dukes and peers, archbishops, bishops, and some other exalted personages, and used in addressing them. *Monseigneur* simply was, before the Revolution, the title given to the dauphin. *Monsieur* is now the common title of courtesy and respect in France; and previously to the revolution in 1830, *Monsieur* simply was the title of the eldest brother of the king.

MONSOO'NS. (From a Malayan word signifying *seasons.*) In Physical Geography, the name given to a certain modification or disturbance of the regular course of the trade winds which take place in the Arabian and Indian seas. Between the parallels of 10° and 30° south latitude the eastern trade wind blows regularly; but from the former parallel northwards the course is reversed for half the year, and from April to October the wind blows constantly from the south-west. During the other six months of the year the regular north-east trade wind prevails. The south-west monsoon is supposed to be occasioned by the great rarefaction of the atmosphere over the extensive regions of Eastern Asia during the summer months. *See* TRADE WINDS.

MO'NSTER. (Lat. monstrum.) Any thing out of the common order of nature is occasionally designated by this term; but it is physiologically employed under a more limited acceptation, and applied to animals in which one or more parts of the body present some congenital malformation. This is sometimes apparent externally, and then must amount to something exceeding any ordinary deformity; or it may be confined to internal organs. Buffon, Blumenbach, and Meckle have treated on monstrosity, classifying its modifications under three heads: the first including cases in which parts of the body are increased in number; the second those where certain organs are deficient; and the third including cases in which size, situation, and structure are concerned. Other writers, such as Geoffroy St. Hilaire (*Histoire des Anomalies*), have adopted more comprehensive arrangements; arising, however, out of the general subdivision of monsters into simple and compound: the former including all cases in which the elements of a single individual only are concerned; the latter those in which the constituent parts of two or more individuals are united. Simple monsters have again been distributed into three classes. The first including such varieties of malformation as chiefly affect one organ or system of organs, without materially interfering with any vital function: these anomalies are extremely numerous, and have been further subdivided into cases where size, form, or structure is affected, and those in which the malformation affects the arrangement, connection, or number of parts. The second class in this arrangement includes cases of extensive malformation, attended by great deformity and by disturbance of vital functions. The third class is limited to malformations of the organs of generation, including among others the various cases miscalled hermaphrodites. The history of individual cases of monstrosity would be here misplaced; several of the most remarkable are detailed in various volumes of the *Philosophical Transactions;* in the *Transactions of the Medico-Chirurgical Society;* and in the *Penny Cyclopædia*, art. "Monster."

MO'NSTERS, or CHIMERICAL FIGURES. In Heraldry, a species of bearings, of which some are very common in English coats of arms, and others common in foreign, although not often used in our own. The sagittary or centaur, man-tiger, sphinx, harpy, triton, and mermaid, are monsters compounded of the human and bestial shape. Of monstrous beasts, the most common in armorial bearings are the dragon, the griffin (a compound of the eagle and the lion), the wyvern (a two-legged dragon): besides these, there are the unicorn, the heraldic antelope, tiger, and ibex (which are chimerical figures, but representing the natural beast), the musimon (an animal between the goat and the sheep), and the salamander. Monstrous birds are the phœnix, cannet, martlet, allerion, cockatrice, &c.

MONTA'NISTS. Heretics of the second century, who derive their name from their founder Montanus, a Phrygian, who pretended to inspiration, and declared himself to be a prophet sent from God to complete the Christian scheme, and advance it to its highest state of perfection. He affirmed himself to be the Paraclite or Comforter, whose mission was supposed by various sectarians of the early centuries to be distinct from that of the Holy Spirit, which was promised to the apostles, and was expected to put the finishing stroke to the revelation of Jesus Christ. The characteristics of this sect were similar to those which are known by the general name of Gnostic, and consisted principally in great austerity of manners, and a belief in the possibility of an advance from the obvious and literal interpretation of the word of God to a state of interior and spiritual knowledge coincident with a participation in the divine nature itself.

MO'NTANT. (Fr.) In Architecture, any upright piece in a system of framing.

MONT DE PIÉTÉ. (Ital. Monte di Pieta.) The name given on some parts of the Continent to certain benevolent institutions, established for the purpose of lending money to the poor at a moderate rate of interest. They originated under the papal government in the 15th century, and were intended to countervail the exorbitant usurious practices of the Jews, who formed at that period the great money-lenders of Europe. These institutions were afterwards introduced into many of the Continental states; and similar establishments existed, and in some cases still exist, at Paris, Madrid, Brussels, Ghent, Antwerp, &c., *Monti frumentarii* are public granaries, from which corn is sold to the necessitous Italians, on a principle somewhat analogous to that on which sums are lent by the Mont de Piété.

MO'NTEM. The name given to an ancient custom still prevalent among the scholars of Eton, which consists in their proceeding every third year on Whit Tuesday to a tumulus (Lat. *ad montem*, whence the name), near the Bath road, and exacting money for *salt*, as it is called, from all persons present or passers by. The sum so collected is given to the *captain*, or senior scholar of the school, and is intended to assist in defraying the expenses of his residence at the university, to which he is about to proceed. The origin of this ceremony dates from the establishment of the foundation of Eton College; but it was at first held on the 6th of December, the festival of St. Nicholas, the patron of children; and it is only since 1759 that the present was substituted for the original period of its celebration. It has been the almost invariable practice of the sovereign, the court, and a large portion of the nobility to honour this festivity with their presence; and so liberal have been their contributions that the *salt money* has been known to approach nearly 1000*l.* (See *Huggett's MS. Collections*, for a history of Windsor and Eton colleges, in the British Museum; and *Brand's Popular Antiquities.*)

MONTH. (Germ. monat.) The twelfth part of our calendar year. It is so called from its being the period of the moon's revolution round the earth. *See* CALENDAR.

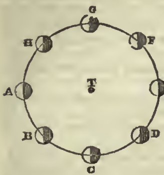
MO'NUMENT. (Lat.) A memorial for perpetuating the remembrance of an event; also a cenotaph in memory of the dead. The productions of architecture and sculpture intended to transmit to posterity the memory of individuals and events are most generally called monuments. Among those in honour of individuals are tombs and sepulchral edifices or columns. The most ancient are the obelisks and pyramids of Egypt; and perhaps, contemporary with these, the tombs of the Persian kings, still visible in the ruins of Persepolis. Greece abounded with monuments of this nature. Buildings in that country were frequently raised in commemoration of distinguished persons or events; and of this class were the Choragic monuments, in honour of those who had received the prize as *choragi* in the theatrical and musical games. Of these the most splendid is the choragic monument of Lysicrates, vulgarly called the Lantern of Demosthenes. Among the monuments of this class of the Romans, the triumphal arches are in the first rank. The column called the Monument of London, and the Duke of York's monument, illustrate respectively the definition above given.

MOOD. (Lat. modus.) In Grammar, the designation by the form of the verb of the manner of our conception of an event, or fact; whether as certain, contingent, possible, desirable, or the like. *See* GRAMMAR.

MOOD OF A CATEGORICAL SYLLOGISM, in Logic, is the designation of its three propositions in the order in which they stand, according to their quantity and quality.

MOON, (Gr. μηνη, Germ. mond.) The satellite of the earth. The moon, after the sun, is not only the most conspicuous, but, in an astronomical point of view, the most interesting of the celestial bodies. The variety of her phases, her eclipses, and the rapidity with which she changes her place among the fixed stars, drew the attention of the earliest observers of the heavens; and in modern times the important application of the theory of her motions to navigation and the determination of terrestrial longitudes, has given the *Lunar Theory* the first rank among the objects of astronomical science.

Phases of the Moon. The different phases of the moon were probably the first celestial phenomena that received a correct explanation. By observing them attentively during the course of a single revolution, it would be inferred that they are occasioned by the reflection of the sun's light from the spherical surface of the moon; and accordingly the fact had been recognised by the earliest astronomers. Let T be the place of the earth, and A B C D E F G H successive portions of the moon in her orbit, the sun being supposed to be situated in the straight line T A, and at so great a distance that lines drawn from it to every part of the moon's orbit may be regarded as parallel. When the moon is at A, she is in *conjunction* with the sun, and passes the meridian at the same time; and her illuminated hemisphere being then turned directly away from the earth, no portion of her disk is visible.



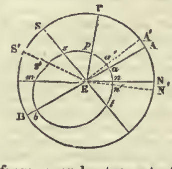
A few days after the conjunction the moon begins to appear on the eastern side of the sun at B, having the form of a crescent, the horns of which are turned away from the sun. When she arrives at C, or 90° from her conjunction, the earth is in the plane of the great circle of her orb, which forms the boundary between her dark and illuminated hemispheres, and consequently half the disk is visible. The moon is then in her *first quarter*. At D more of the illuminated hemisphere is turned towards the earth, and she appears gibbous. At E she is in opposition to the sun; the illuminated side is turned directly to the earth, and the disk appears round or *full*. After passing E the disk begins to wane, and from E to G appears gibbous. When at G, or 270° from the conjunction, she is in the *third quarter*. From this point to the conjunction the moon again appears as a crescent, becoming narrower as she approaches to A; but the horns of the crescent are now turned westward, that is, away from the sun. The straight line which joins A and E is called the line of the *syzygies;* that which joins C G is the line of the *quadratures;* and the points B D F H, situated at equal distances from those lines, are called the *octants*. The magnitude of the illuminated portion of the disk is thus seen to depend on the position of the moon relatively to the sun and the earth, and is easily determined by a geometrical construction. The mean period of time in which a revolution of the phases is completed, or in which she passes from one conjunction to the following, is 29 days, 12 h. 44 m. 2·8 sec.

Distance and Magnitude of the Moon. — The moon's distance from the earth is found from her horizontal parallax, which may be determined either by simultaneous observations at stations very distant from each other, or by means of the occultations of fixed stars by the moon. From such observations it is found that the amount of the parallax varies considerably at different times. Its mean value gives the average distance of the moon from the earth, equal to 59·9 of the earth's equatorial semidiameters, or about 237,000 miles, which is upwards of 400 times less than the distance of the sun. Combining this result with the apparent magnitude (31′ 26″) of the moon's diameter, when at her mean distance, it results that the diameter of the moon is to that of the earth in the proportion nearly of 3 to 11; whence the volume of the moon is only about 1-49th of the volume of the earth.

Inclination and Nodes of the Lunar Orbit. — The moon's orbit is inclined to the ecliptic under an angle of 5° 8′ 47″·9; but the line in which it intersects the ecliptic, or the *line of the nodes*, does not maintain a fixed position on the plane of the ecliptic. It is observed that the moon passes from one of the nodes to the opposite one in less time than is required to pass through 180° of longitude; hence the line of the nodes has a retrograde motion on the ecliptic; and its motion is so considerable that it completes a revolution, or returns to its former position, in a period of 6798·28 days, or about 18·6 years. This period is remarkable, as being that after which the eclipses of the sun and moon again return nearly in the same order. The cause of the regression of the line of the nodes is the attractive power of the sun, which is always tending to draw the moon into the plane of the ecliptic, and which would at length cause her orbit to coincide with that plane, were the tendency not counteracted by the angular motion of the moon round the earth. By reason of the angular motion the mean inclination remains the same, and the resulting effect is the retrograde motion of the nodes. But as the sun's distance from the earth is a variable quantity, the effect of the solar action in displacing the moon's orbit is also variable. Hence, and also on various other accounts, the motion of the nodes, and the inclination of the lunar orbit to the ecliptic, are subject to certain periodical changes, all which must be accurately appreciated and computed in the formation of the lunar tables. *See* PERTURBATIONS.

Eccentricity of the Lunar Orbit. — The general orbit of the moon is an ellipse, having the earth at one of its foci; but on account of the disturbing force of the sun, and the difference of the intensities of this force when the moon is differently situated relatively to the earth and sun, the ellipse is constantly changing its form and position on the plane of the orbit; and hence the numerical values assigned to all its elements are to be considered only as average or mean values. The distance of the moon from the earth when in *apogee*, or at her greatest distance, is 63·842 semidiameters of the earth; and when in *perigee*, or at her least distance, 55·916 semidiameters; whence the eccentricity, or distance of the focus form the centre, is about 0·066, half the major axis being taken as unity. According to the best tables, it is 0·0548442. On comparing the positions of the major axis, which is called the line of the *apsides*, at different times, in respect of the fixed stars, it is found to have a rapid motion eastward, completing a whole circuit in 3232·57 mean solar days, or nearly nine years. But this mean motion is subject to inequalities of considerable magnitude. The different situations of the line of the apsides with respect to the line of the syzygies gives rise to the inequality of the lunar motion, called the *evection*. *See* EVECTION.

Different Species of Lunar Months. — As the principal points of the lunar orbit — the syzygies, the nodes, the apsides,—are in a state of rotation with different velocities, and in different directions, it follows, that the period of time in which the moon completes a revolution with respect to any of these points, or to the fixed stars, will be different in each case. These periods, which are called lunar *months*, may be explained as follows: — Let E be the centre of the earth, *a s b t* the orbit of the moon, *a b* the transverse axis or line of the apsides, *s t* the line of the syzygies, *n m* the line of the nodes, and A S B N the great circle of the sphere in the plane of the ecliptic. Also, let P be a fixed point on this circle; and suppose the moon to be at *p*, or seen in the direction E P.



The time which elapses while the moon passes from *p*, and returns to the same point of the ecliptic, is called the *tropical* revolution, and differs only about seven seconds from the time in which the moon returns to the same fixed star, or performs a *sidereal* revolution. Suppose now the moon to be at *s*, in the line of the syzygies; when the moon advancing from *s*, in the direction *m b n*, has again come round to the same point of the ecliptic, she will not now be in conjunction; for, in the interval, the sun has advanced from S to S′ (nearly a twelfth of the circumference), and consequently the moon must go on to *s′*, till she overtakes the sun, before she returns to her conjunction. The interval from conjunction to conjunction is the *synodic period*, and exceeds the tropical period by two days and about five hours. Next, suppose the moon to be at her perigee *a*, or seen in the direction E A; while the moon, after leaving *a*, is describing her orbit, the line of the apsides E A revolves through the angle A E A′, and consequently the moon, after coming into the line E A, must continue to advance till she comes to *a′* before she arrives again at her perigee. The interval from perigee to perigee is called the *anomalistic period;* and it is also longer than the tropical period, though much shorter than the synodic, inasmuch as the line of the apsides requires about nine years to complete its revolution, while that of the syzygies is completed in one year. Lastly, suppose the moon at *n* in the line of the nodes. While the moon is advancing round her orbit, the line of the nodes, E N, moves backward into the direction E N′; consequently the moon will have come up to her node at *n′* before she has completed a revolution on the ecliptic. The interval from node to node is called the *nodical period*, and is shorter than any of the other periods. The following table exhibits, in mean solar days, the mean lengths of the different lunar periods or months: —

	Days.
Synodic revolution - - -	29·53059
Sidereal - - -	27·32166
Tropical - - -	27.32158
Anomalistic - - -	27·55460
Nodical - - -	27·21222

Acceleration of the Moon's mean Motion. — On comparing observations of the moon made at distant times, it has been discovered that her mean motion has been undergoing a constant acceleration since the earliest times. This acceleration is, however, extremely small, amounting only to 10″ in a century, and therefore is in-

sensible for any moderate interval of time, though it becomes discernible after a few centuries. Being measured by centuries, it is called the *secular acceleration* of the mean motion. Its physical cause was found by Laplace to be a diminution of the eccentricity of the earth's orbit.

Eclipses of the Moon. — The diameter of the sun being much greater than that of the earth, the earth must project behind it in space a conical shadow, the axis of which is in the plane of the ecliptic, and in the straight line joining the earth and sun. On computing from the relative magnitudes of the earth and sun and the distance of the two bodies the length of this shadow, it is found that it reaches to about 216 times the radius of the earth, and consequently far beyond the orbit of the moon. It is found also that the apparent diameter of the conical shadow, at the mean distance of the moon, is about 1° 23′. But the greatest apparent diameter of the moon being only 33′ 31″, or about a third of this distance, it follows that if the moon happens to be situated in the plane of the ecliptic when she is full, or in opposition with the sun, the whole lunar disk will be enveloped in the earth's shadow; and as the moon requires about an hour to pass over a space equal to her own breadth, the whole disk may be involved in the shadow, and the moon remain invisible during a space of about two hours. This phenomenon is a *total eclipse* of the moon; and it is evident that if the moon's orbit coincided with the ecliptic, a total eclipse would take place every lunation. In consequence, however, of the inclination of the orbit to the ecliptic, the moon at the time of her opposition is in general so far from the ecliptic that her disk does not come into contact with the earth's shadow, and consequently no eclipse takes place. The occurrence of the eclipse, therefore, depends on the distance of the moon from her node at the time of the opposition; and it results, from the computation of the different circumstances influencing the phenomenon, that the eclipse *may* take place if the moon is within about 12° of her node, and *must* take place if the distance from the node is not greater than 7°.

Eclipses of the Sun by the Moon. — A solar eclipse is occasioned by the moon's body coming between the spectator and the sun, and thereby intercepting the rays coming from the whole or a part of his visible disk. This phenomenon, like an eclipse of the moon, can only happen when the moon is near one of her nodes; but a total obscuration does not necessarily take place, even when the moon is in the ecliptic at the time of her conjunction; for the magnitude and distance of the moon are so related that the apex of her conical shadow sometimes falls short of the earth's surface, though at other times it would reach as far as the earth's centre. When the umbra extends beyond the earth's surface, its intersection with the surface marks out a circular spot, within which no part of the sun's disc is visible, and there is a total eclipse. For some distance around this spot, that is to say, within the *penumbra*, a part only of the sun will be visible, or there will be a partial eclipse. When the apex of the shadow does not extend to the earth, there will be no total eclipse at any part of the earth; but a spectator situated in or nearly in the prolongation of the axis of the cone, will see the whole of the moon on the sun, though not large enough to cover it; that is to say, he will witness an *annular* eclipse. For the method of calculating eclipses of the sun and moon, see ECLIPSE.

Rotation and Libration of the Moon. — From the observation of the lunar spots, it is ascertained that the moon has a motion of rotation about an axis nearly perpendicular to the plane of her orbit; and, what is very remarkable, the period of rotation is *exactly* equal to that of her sidereal revolution about the earth. Hence, the same hemisphere of the moon is always turned towards the earth; but as the rotation is uniform, while the motion of revolution about the earth is sometimes faster and sometimes slower than the mean, the line which joins the centres of the earth and moon does not intersect the lunar surface always at the same point, but fluctuates a little to the eastward and westward of its mean place, whence the spots near the eastern and western borders of the disk alternately disappear and are brought into view. This phenomena is called the *libration in longitude.* Moreover, as the moon's orbit is inclined to the ecliptic in an angle of 5° 8′ 47·9″, while the plane of her equator makes with the ecliptic an angle of only 1° 30′, the axis of rotation is not exactly perpendicular to the plane of the orbit, whence her poles come alternately into view for a small space round the northern and southern borders of the disk. This is the *libration in latitude.* There is also a *diurnal libration*, occasioned by the moon's being seen from the surface instead of the centre of the earth. *See* LIBRATION.

Appearance and Physical Constitution of the Moon. — On looking at the moon with the naked eye, her disk appears diversified by dark and bright patches, which, on being examined with a good telescope, are discovered to be mountains and valleys. That the whole surface of the moon is covered by such inequalities is evident from the circumstance that the line of separation between the illuminated and dark hemispheres, which, if the surface were even, would be a sharply defined ellipse, is at all times extremely ragged, and indented with deep recesses and prominent points. The mountains near this line cast behind them long black shadows (like mountains on the earth when the sun is in the horizon), from the micrometrical measurement of which the height of the mountains may be calculated. According to Sir J. Herschel, some of the highest of them exceed 1¾ English miles in perpendicular altitude. Tycho, the bright spot in the south-east quarter from which the rays seem to run, is apparently a volcanic crater, 50 miles in diameter and 16,000 feet deep, surrounded by broad terraces within, and with a central mountain about 5000 feet high. Schroeter has estimated the average height of the lunar mountains to be upwards of 5 English miles; but it is easy to see that the measurement is not susceptible of much accuracy.

"The generality of the lunar mountains," says Sir J. Herschel, "present a striking uniformity and singularity of aspect. They are wonderfully numerous, occupying by far the larger portion of the surface, and almost universally of an exactly circular or cup-shaped form, foreshortened, however, into ellipses towards the limb; but the larger have for the most part flat bottoms within, from which rises centrally a small, steep, conical hill. They offer, in short, in its highest perfection, the true volcanic character, as it may be seen in the crater of Vesuvius; and, in some of the principal ones, decisive marks of volcanic stratification, arising from successive deposits of ejected matter, may be clearly traced with powerful telescopes. What is, moreover, extremely singular in the geology of the moon is, that although nothing having the character of seas can be traced (for the dusky spots which are commonly called seas, when closely examined, present appearances incompatible with the supposition of deep water), yet there are large regions perfectly level, and apparently of a decided alluvial character." ("Astronomy," *Cabinet Cyclopædia*, p. 229.)

The moon has no atmosphere, or at least none of sufficient density to refract the rays of light in their passage through it. There is consequently no water on her surface; and no animal similarly constituted to those which inhabit the earth could subsist there. Her surface presents no appearance of vegetation, or of variation which can be ascribed to a change of seasons. Every thing appears solid, desolate, and unfit for the support of animal or vegetable life. Whether the materials of which the lunar substance is composed are of the same nature as those which compose the earth there are no means of knowing. From the effect of the moon's gravitation in producing the nutation of the earth's axis, the mass of the moon is determined to be very nearly 1-80th of the mass of the earth; whence, as her volume is only 1-49th of the earth's volume, it results that her density, as compared with the mean density of the earth, is ·615, or a little more than one half.

MOO′NSTONE. A variety of *adularia*, or resplendent felspar; it occurs massive and crystallized. Select specimens are sometimes cut into ring and brooch stones.

MOOR. An uncultivated surface without trees, and with few grasses or other herbage fit for pasture; and generally containing scattered plants of heath, with a dark peaty soil. Moor lands are generally the least fitted for culture of any description of surface not rocky or mountainous. Moors are covered with a very thin layer of soft, black, sterile soil; and the subsoil is generally gravel, or retentive ferruginous clay. By the destruction of the heath, or other bad herbage, and by sowing down with grass seeds, they may be improved. In many cases, also, trees will grow on drained moors; in which case the soil ultimately becomes ameliorated by the fall and decay of the leaves.

MOOR, in Navigation, signifies generally to fix a vessel by two anchors in nearly opposite directions, so that she *rides* by either in certain winds, or partly by both in other winds. Also to secure a vessel to weights or chains sunk in harbours for the purpose. These weights are called *mooring blocks*, and the whole apparatus *moorings*.

MOO′RISH ARCHITECTURE. *See* ARCHITECTURE.

MO′PLAHS. The Mahometan inhabitants of Malabar, descended from Moors and Arabians who have settled on that coast and married Malabar women. They are said to form a fourth of the population. They are commercial and industrious on the coast, but a furious race in the interior. (Forbes, *Oriental Memoirs*, p. 258.)

MORAI′NE. The name given in Switzerland and Savoy to the longitudinal deposits of stony detritus which are found at the bases and along the edges of all the great glaciers. The formation of these deposits are explained by Professor Agassiz as follows: — The glaciers, it is well known, are continually moving downwards, in consequence, probably, of the introduction of water into their fissures, which, in freezing, expands the mass; and the ice being thus loosened or detached from the rocks below, is continually pressed forward by its own weight.

In consequence of this motion the gravel and fragments of rocks which fall upon the glaciers from the sides of the adjacent mountains are accumulated in longitudinal ridges, or *moraines*. From the existence of such deposits in many places where there are now no glaciers, combined with the polished appearance of the surfaces of the rocks on the sides of valleys, supposed to have been produced by the friction of moving glaciers, Professor Agassiz infers that the extent of glaciers was formerly much greater than it now is, and that they covered the great valley of Switzerland, with the whole chain of the Jura. (Agassiz, *Etudes sur les Glaciers de la Suisse; Reports of the British Association for* 1840.)

MORALS. *See* ETHICS.

MORA'NA. The old Bohemian goddess of winter and of death: the Maryana of Scandinavia. A grand yearly festival was celebrated in honour of this goddess in the month of March. Her image was conveyed solemnly to the nearest brook or rivulet, and thrown into it amid the rejoicings of the people. This festival was called "Das Joden-Austreiben, das Sommer gewinnen;" and, as the words imply, was intended to be symbolical of the end of winter and the return of spring. (See *Grimm's Deutsche Mythologie*, p. 446.)

MORA'SS. Moor lands saturated with water to such an extent as not to bear the tread of cattle. A morass is to a moor what a marsh is to a meadow. It is evident that the drainage of morasses and moors, by lessening the evaporation of water from their surfaces, must tend to improve the local climate.

MORAVIAN BROTHERS. *See* HERRNHUT.

MORBIDE'ZZA. (Ital.) In Painting, a softness and delicacy of style. Its opposite is a style whose lines are harsh and angular.

MO'RDANT. A substance used to fix colouring matters upon different stuffs. (*See* DYEING.) Alumina and oxide of iron are the most important mordants.

MORDE'LLA. (Lat. mordeo, *I bite.*) A Linnæan genus of Coleopterous insects, the type of a family (*Mordellidæ*) of Latreille's *Heteromerans*, distinguished by the general form of the body, which is elevated and arched; with the head low; the thorax trapezoid or semicircular; the elytra very short, or narrow and pointed at the tips, as well as the abdomen. They are distinguished from their nearest congeners, as the *Pyrochroidæ*, by their extreme agility, the firm texture of their integuments, and their tenacious and painful bite. The subgenera of the *Mordellidæ* are *Ripiphorus*, *Myodites*, *Pelecotoma*, *Anaspis*, and *Mordella* proper: to the last subgenus are now restricted the species of the present family, which have the antennæ of equal thickness throughout, and slightly serrated in the males; the eyes not emarginate, and the abdomen terminated by a long point.

MORDE'NTE. (Ital.) In Music, a grace in use by the Italian school, which is effected by turning upon a note without using the note below.

MO'REL. (Germ. morchel.) The *Morchella esculenta* is one of the few fungi found in this country which may be used as food with safety. It occasionally occurs in woods and orchards, whence it finds its way to the markets; but it is of comparatively rare occurrence. It has a hollow stalk an inch or two high, and a yellowish or greyish ribbed head two or three inches deep.

MORE'SQUE. (Fr.) In Painting, a species of ornamental painting, in which foliage, fruits, flowers, &c. are combined, by springing out of each other, without the introduction of the human figure, or that of any animals; and receiving its name from having been much used by the Moors, who, however, were not the inventors of it.

MORGANA'TIC MARRIAGE, or LEFT-HANDED MARRIAGE. (Said to be derived from the Gothic word morgjan, *to shorten.*) A marriage between a man of superior and a woman of inferior rank, in which it is stipulated that the latter and her children shall not enjoy the rank or inherit the possessions of her husband. Such marriages are not uncommon in the families of sovereign princes, and of the higher nobility, in Germany; but they are restricted to personages of these exalted classes.

MORGUE. (Fr.) The name given to a place in many French towns where the bodies of persons found dead are exposed in order to be recognized and owned by their friends. The clothes in which they were found are placed near the bodies, for their better identification. The Parisian morgue is built on the left bank of the Seine, in one of the most populous neighbourhoods of the city, and presents one of the most disgusting spectacles that can be witnessed anywhere.

MO'RMON. (Gr. μοϱμων, *a mask.*) The generic name for the short-winged web-footed birds, usually called Puffins, the singular beak of which gives the head the appearance of a grotesque mask. The depth of the base of the bill equals that of the entire head, and frequently the length of the bill itself: the mandibles are compressed, arched, obliquely channelled, and notched towards the tip. The eggs and young birds are sought after and taken in great numbers in the Orkneys and Faroe Isles.

MORMY'RUS. (Gr. μοϱμυϱος, a name given by the Greeks to a shore-frequenting fish of a variegated colour, probably the *Sparus mormyrus* of Linnæus.) The name was applied by Linnæus to a genus of abdominal fishes placed in the Malacopterygian order, between the *Lucioid* and *Siluroid* families in the system of Cuvier. The *Mormyri* differ from the pikes in little else save in the small size of their mouth, of which the angles are formed by the maxillary bones; and a corresponding modification of the alimentary canal, the intestines being longer, and complicated by two cæca. The *Mormyri* are confined to the rivers of Africa, and are reckoned the best-flavoured fishes that are caught in the Nile.

MORO'CCO. (Fr. maroquin.) A species of goatskin leather, originally imported from the Levant and Barbary states. It is extensively used in the binding of books. *See* LEATHER.

MO'ROXITE. (Lat. morus, *the mulberry tree.*) A mineralogical name applied to one of the varieties of native phosphate of lime of a mulberry colour.

MOROXYLIC ACID. An acid discovered by Blaproth, combined with lime, in the bark of the *Morus alba*, or white mulberry tree.

MO'RPHEUS. In Ancient Mythology, the god of dreams; the son of Ὕπνος or Somnus, who presided over sleep, with whom he is frequently confounded. The chief distinction between them appears to be this — Morpheus had the power of assuming only the human shape, while the transformations of Somnus were unlimited. He is generally represented as a beautiful youth, with a bunch of poppies in his hand.

MO'RPHIA. (Lat. Morpheus, the god of dreams.) The narcotic principle of opium. It may be separated from opium in the form of white prismatic crystals almost insoluble in water, but soluble in boiling alcohol; it combines with the acids and forms salts, all of which are powerful sedatives, and have proved of great value as medicines. Of these the muriate of morphia is perhaps the best. It is composed of about 288 morphia (which is its equivalent) and 37 muriatic acid. One of the most characteristic chemical properties of morphia and its salts is that they decompose iodic acid, and consequently immediately discolour its aqueous solution. The ultimate elements of morphia are carbon, oxygen, hydrogen, and nitrogen.

MO'RPHNUS. (Gr. μόϱφνος, a name applied by Aristotle to the osprey.) This term is restricted by Cuvier to a genus of *Accipitres* called eagle-hawks, having wings shorter than the tail, but with long and slender tarsi and comparatively feeble toes. Some species have the tarsi naked and scutellated, as the *Morphnus guianensis*.

MORPHO'LOGY. (Gr. μοϱφη, *form*, and λογος, *description.*) That department or division of the science of botany which treats of the metamorphosis of organs. It appears, from the comparison of one kind of organ with another, that notwithstanding the differences between them, there are so many close analogies, and so much identity of structure, as to render it probable that they are all formed upon one common plan, modified according to the purposes for which they are severally destined. The leaf, which is the most universal of the external organs, is taken as the best representation of this type; and with the more reason, because all the other parts are found to have a tendency to assume the organization of a leaf, when any disturbing cause interferes with their development. According to morphological writers, the scale of a leafbud is a rudimentary leaf; the petal is a leaf reduced in size, and thinned or coloured, or both; the stamen is a leaf, whose petiole is represented by the filament, while the two lobes of the anther are the two sides of its lamina; and the pollen is the disintegrated mesophyll, and so on. These conclusions were for a long time ridiculed by many writers; but they gradually gained ground with philosophical botanists, and are now the foundation of comparative anatomy in plants. At the present day the question is indeed no longer speculative, but is decided by the evidence of our eyes; for all those transformations, the necessity of which morphologists assumed by mere force of reasoning, have now been witnessed by Schleiden and many others, who have traced the development of the organs of plants from their earliest condition, through all their modifications, up to the period of complete development, and have found that they are all deviations from a common type subsequent to the first stage of their growth.

MO'RRIS DANCE. A peculiar kind of dance practised in the middle ages. It is supposed to have been first introduced into England from Spain by Edward III., when John of Gaunt returned from that country; but few traces of it are found earlier than the times of Henry VIII.; and it is more probable that it was borrowed either from the French or the Flemings. In the morris dance bells were fixed to the feet of the performer, and the great art consisted in so moving the feet as to produce something like concord from the various bells.

MORS. In Ancient Mythology, the daughter of Night without a father, and goddess of death. The most sub-

lime representation of death personified is to be found in the *Paradise Lost*.

MORTA'LITY, BILLS OF. Bills of Mortality are extracts from parish registers, showing the numbers who have died in some fixed period of time, as a year, a month, or a week; and hence they are called yearly, monthly, or weekly bills. In general, they also contain the numbers of baptisms, and sometimes the numbers of marriages.

The keeping of parish registers was begun in England in the year 1538, in consequence of an injunction issued by Lord Cromwell, the king's vicegerent in ecclesiastical affairs, after the abolition of the papal authority in the kingdom. In Germany they appear to have been introduced at a somewhat earlier period, for Sussmilch has given extracts from the Augsburg bills which go back to the year 1501; and they were established in most countries of Europe about the beginning of the seventeenth century.

The London bills, containing the records of the baptisms and deaths, were begun in the year 1592, but were not kept regularly till after the plague which prevailed in 1603; since which time they have continued weekly, and an annual bill has been also regularly published. Their value, however, was very little understood; nor do they seem to have attracted much notice until 1662, when Graunt published his *Natural and Political Observations on the Bills of Mortality*, a work of great merit, considering the time at which it was written. The ages at which the deaths took place were not inserted in the bills till 1728. Throughout the country the registers were kept, generally speaking, with very little care; but the recent act for the registration of births, marriages, and deaths, which came into operation in 1836, has introduced an incomparably better system; and, as the sex, ages, and causes of death are now recorded, the public will soon be in possession of far more authentic information than has yet existed on some of the most interesting questions of social statistics. (See article "Mortality," in the *Encyc. Brit.*; Preface to the *Population Returns for* 1831; *Annual Reports of the Registrar General of Births, Deaths, and Marriages in England*, 1839, *et seq.*)

MORTA'LITY, LAW OF. By this term is usually understood a mathematical relation subsisting among the numbers of persons living at the different ages of life; such that, having given the number of persons living at any assigned age, the number of them who remain alive at every subsequent age, and consequently the mortality which takes place in the interval, will be expressible by that relation. It must be obvious that, in speaking of a law of this kind, we can only have regard to the averages of large numbers. In respect of a single individual, or a small number of persons, the uncertainty of the duration of life is proverbial; but the case is entirely changed when multitudes are concerned; and there are few classes of contingent events of which the results can be predicted with so little risk of departure from the truth as the average age to which the lives of a considerable number of persons will be prolonged.

The circumstances which affect the mean duration of human life depend upon a great number of different causes; as climate, the facility of obtaining subsistence, the state of civilization, the manner of living, progress of medical science, &c., all of which vary in different countries and at different times. The law of mortality, therefore, must vary with these circumstances; and consequently, if expressible by any mathematical function, it must be one affected by numerical coefficients depending on the particular circumstances, and of which the values can only be determined by observation. The simplest expression which has been proposed for representing the course of mortality is that which is derived from the celebrated hypothesis of Demoivre; namely, that, if a number of individuals be taken in any given year of age, the number of deaths which take place among them will be the same every year until the whole are extinct. In this hypothesis only one numerical quantity requires to be determined, which is the average extreme age. Demoivre adopted 86; and his hypothesis may therefore be simply enunciated as follows: — Out of 86 infants born, 85 will be alive at the end of the first year, 84 at the end of the second, and so on to the extremity of life, the decrement being one in each year. For a considerable number of years, about the middle ages of life, this hypothesis of equal decrements represents the observed facts with tolerable accuracy; and, as it affords considerable facilities in various calculations, it was formerly much used in the computation of life contingencies.

If we suppose a straight line to be divided into a number of equal parts, representing the ages of human life, and perpendiculars to be drawn through the points of division proportional to the number of survivors at each age out of a given number taken at a previous age; a curve line drawn through the extremities of all those perpendiculars will represent the law of mortality as indicated by the observations, and the equation of the curve will be the relation between the age and the mortality. Now it is possible to draw an algebraic curve through any number of points; but, in the present case, this method of proceeding is attended with no advantage; for if the number of points be great, as it necessarily must, the equation is of a high order, and its numerical computation impracticable. Lambert, of Berlin, who appears to have been the first who exhibited the law of mortality by a curve line, constructed a somewhat complicated empirical formula, which represented the mortality observed in London during some part of the last century with considerable accuracy, and which may be adapted to any other set of observations by giving suitable values to its numerical coefficients. But the most ingenious attempt which has been made to deduce a formula from *à priori* considerations is contained in a paper by Mr. Benjamin Gompertz, published in the *Philosophical Transactions for* 1825. Mr. Gompertz assumes as a principle that there is a power in human life to resist the effects of disease, or oppose destruction, which loses equal proportions of its intensity in successive equal small intervals of time; and from this he derives an expression which gives the number of survivors (y) of any number of individuals, taken at any given age, at the end of any number of years (x) counted from that age, in terms of three constants, which may be determined from observations. The formula may be given under this form: —

$$\log. y = \log. l \pm \text{No. whose log. is } (\log. \log. p + x \log. q),$$

l, p, and q being the constants to be determined. On assuming three ages, and taking the corresponding values of x and y from the Carlisle table, and determining the constants by means of the three equations so formed, the formula is found to agree with the table through all the ages, within limits which may be fairly supposed not to exceed the errors of the observations.

On account of the multitude of causes which influence the rate of mortality among the inhabitants of a country, it is plain that any formula deduced from *à priori* considerations can only be trusted so far as it is found to agree with experience; and therefore, for all practical purposes, recourse is had to a table showing for each year of age the number of deaths which are observed to take place out of a large number of persons who enter upon that age. The ratio of those two numbers is the measure of the probability that an individual entering upon that age will not survive the year, and may be assumed as the law of mortality in respect of that age. The table may be exhibited under different forms: the most usual is a table of decrements, which is constructed by supposing a large number of persons, as 10,000, for example, to start together in the same year of age (the year of birth is usually assumed), and to write down in the same column the number of them who remain alive at the end of each successive year. From this the number who die in each year, and the chances of surviving a year, or any number of years, are easily found. For some purposes a table of the probabilities of living over a year at each age, or of dying in the course of the year, is more convenient; but either form can be readily reduced to the other.

The oldest table of mortality we possess is published in the *Philosophical Transactions for* 1693, and was constructed by Halley from the mortuary registers of the town of Breslaw, in Silesia. This town was selected, because the number of births having been nearly equal to the number of deaths for some years, it might be assumed that the population had remained in a nearly stationary state during that time, — an assumption which affords the means of determining the ratio of the number who die at each age to the number who entered upon that age; for it is evident that in a place so circumstanced, and supposing also there is no migration, the number who survive or complete any year of age within a given period is equal to the sum of the deaths at all the greater ages during the same period. For the sake of facilitating calculations from the table, he reduced the numbers proportionally to 1000, by which number he represented the infants of one year of age.

This method of determining the mortality from the mortuary registers, or *bills of mortality*, has been frequently adopted, particularly by Dr. Smart, in the formation of a table showing the mortality in the city of London about the middle of the last century; by St. Maur, in respect of Paris; and by Dr. Price, for the celebrated Northampton table, presently to be described. But it is evident that as the population of a large town or district of country can never be absolutely stationary, and as migration must be constantly taking place to a greater or less extent, the method is not absolutely correct; and, in fact, the results to which it leads must be attended with great uncertainty. In order to obtain accurate results, it is necessary to know the numbers who actually enter upon each year of age, as well as the numbers who die in that age, during the period included in the observation; and hence, in addition to the mortuary register, an enumeration in each year, or at short intervals,

of the community in the several ages of life, is requisite for the accurate solution of the problem. But, although great attention has been given of late years to the statistics of life, in various countries of Europe, it is only in a very few instances that sufficiently accurate data for the construction of a mortality table have been obtained from observations embracing indiscriminately all the different classes of the inhabitants. Of these few, the principal (if not the only) instances are the observations made in Sweden and Norway; those of Dr. Heysham, at Carlisle; and more recently by Dr. Cleland, at Glasgow.

In consequence of the migration which is constantly going on among the inhabitants, it is very difficult to obtain with certainty the data necessary for determining the mortality of any town or district, even where the registers of births and deaths are accurately kept; but there are various associations of individuals with respect to which precise data exist. Such, for example, are the religious houses in Catholic countries; the tontines which were established in different countries of Europe during the last century; the annuitants of the British government; and especially the assurance companies, which are now become so numerous. In all such associations, the numbers who enter upon and die in each year of age can be ascertained with precision from the records of the association, which, therefore, afford the data requisite for determining the rate of mortality at the different ages, without hypothesis of any kind. Tables were thus constructed by Kersseboom, from Dutch registers of annuitants; by De Parcieux, from the lists of the nominees in the French tontines, chiefly of 1689 and 1696, and from the mortuary registers of the Benedictines, and of the nuns in several convents in Paris; and by Mr. Finlaison, from six different classes of annuitants in English and Irish tontines. Of the assurance offices, the Equitable Society is the only one which has as yet published its experience; but there is little doubt that several of the others have accumulated valuable masses of observations.

We shall now give a comparative view of the mean duration of life at the different ages, computed from some of the best known tables, premising a short account of each table. For the method of making the computation, see EXPECTATION OF LIFE.

1. *Northampton Table.* — This table, which perhaps is better known in this country than any other, on account of its having been adopted by the greater number of the assurance offices as the basis of their tables of premiums, was constructed by Dr. Price, from the bills of mortality from 1735 to 1780 of the parish of All Saints, in the city of Northampton. It cannot be considered as possessing much authority, either on account of the accuracy of the data, or the number of lives of which it embraces the history; and the hypotheses made use of in its formation, — namely, that the number of the inhabitants, and the number of annual deaths, remained the same during the forty-six years included in the observations, and also that the migrations all took place at the age of twenty years,— tend further to render it of doubtful value. It differs from the other tables in giving a much lower expectation of life at the younger and middle ages; and although this may be in part owing to an increase in the average duration of life since the middle of the last century, it is probably owing in a much greater degree to the inaccuracy of the observations. For the history of this table, see *Price on Reversionary Payments*, 4th ed. 1783.

2. *Carlisle Table.* — This was constructed by Mr. Milne, from registers kept by Dr. Heysham of the births and deaths which took place in the city of Carlisle and its environs in the nine years from 1779 to 1787, the number of inhabitants having been determined by two enumerations which were made during that interval. On account of the accuracy of the data, and the skilful manner in which they were made use of, this table is of great value, and probably gives the most correct view of the mortality among the inhabitants of England generally which has yet been obtained. (*Milne's Treatise on Annuities, &c.*, 1815.)

3. *Government Tables.*—These tables, as already mentioned, were computed by Mr. Finlaison, from observations of the mortality among the nominees of life annuities granted by the British government. Mr. Finlaison has given twenty-one tables of the probabilities of life; but the recorded facts are contained in only six of them, the others being formed by combinations of these six. The two columns in the subjoined table, for males and females respectively, are deduced from the rate of mortality adopted by the government for determining the values of life annuities. (*Finlaison's Report to the Lords of the Treasury*, published by order of the House of Commons, 1829.)

4. *Equitable Society's Table.* — This table, which was prepared by Mr. Arthur Morgan, and published in 1834, exhibits the mortality which took place in the society from its establishment in 1760 to the end of the year 1829. By reason of the great number of lives contained in it, and the certainty of the data, this is a document of great importance. It will be seen from the subjoined table that, for ages under fifty, it gives a rather more favourable expectation of life than the government table for males, and agrees nearly with the Carlisle table; but for ages above fifty it gives a less favourable expectation than either of those tables. The observations commence at the age of ten.

5. *The Friendly Society's Table.* — This table was prepared by Mr. Ansell, from materials collected by the Society for the Diffusion of Useful Knowledge. It may be considered as representing the mortality of the labouring classes in England. The observations were from 1823 to 1828. (*Ansell's Treatise on Friendly Societies*, 1835.)

For the sake of avoiding decimal points, the numbers in the subjoined table show the mean duration of life for ten individuals, or the number of years enjoyed by ten individuals collectively. In respect of a single individual, the mean duration of life is the tenth part of the number given in the table.

Age.	Northampton.	Carlisle.	Government. (Males.)	Government. (Females.)	Equitable Society.	Friendly Society.
0	252	387	502	555		
5	408	513	489	542		
10	398	488	456	511	483	
15	365	450	418	472	450	413
20	334	415	384	440	417	376
25	309	379	359	408	381	342
30	283	343	332	376	345	309
35	257	310	302	343	309	276
40	231	276	270	311	274	246
45	205	245	238	278	239	216
50	180	211	203	244	204	187
55	156	176	172	208	170	159
60	132	143	144	173	139	133
65	109	118	116	140	111	109
70	86	92	92	110	87	86
75	65	70	71	85	66	65
80	48	55	49	65	48	48
85	34	41	31	48	34	34
90	24	33	20	28	26	24
95	8	35	12	16	11	8

There are many questions of great interest respecting the law of mortality which cannot yet be satisfactorily answered, from the want of sufficient data. The Carlisle table gives only an indication of local mortality; but it may be asked, whether the mortality is the same in different parts even of the same country, or the same in cities as in rural districts? Now, the government annuitants resided in all different parts of the kingdom; and the same may be said of the members of the Equitable Society, though, perhaps, a majority of the latter were resident in London. But the three tables—namely, the Carlisle table, the table computed from the government male annuitants, and the Equitable Society's table — present a remarkable agreement; and, so far as their evidence goes, we cannot draw any positive conclusion, either in favour of a particular district or a select class of individuals.

It seems to be established beyond doubt that the rate of mortality, at least in England, has undergone a very sensible diminution within a century, especially in respect of children and aged people. This may be ascribed in some degree to the discovery of vaccination; but more especially to the general diffusion of comfort, and the improved mode of living, among the labouring classes of the community.

Another question of great importance is, whether the law of mortality is the same for both sexes? In the above table it will be seen that there is a remarkable disparity between the male and female annuitants in favour of the latter. This indication of the greater longevity of females is confirmed by the observations of De Parcieux on the monks and nuns in the French convents; of Kersseboom, on the Dutch annuitants; of Dr. Price, on the mortality at Chester; and also by the tables constructed from the mortality in Sweden, at Montpellier in France, and in the cities of Amsterdam and Brussels. It is still, however, open to doubt whether the superiority shown in the above instances holds generally true. Over the whole population of Belgium, the greater part consisting of peasantry and labourers, it is found that the lives of females are shorter than those of males; while in the towns the advantage is on the side of the females. We believe the experience of some of the assurance offices shows no superiority in the duration of female life.

The following table, showing the proportion of deaths to the population in the principal states of Europe, according to the latest observations, is extracted from a paper in the *Revue Encyclopédique* for July and August, 1833. We cannot vouch for its accuracy, but it is probably not far from the truth.

Countries.	Periods or Epochs.	Ratio of Mortality to Population.
Sweden and Norway	1821–1825	1 in 47
Denmark	1819	1 45
European Russia	1826	1 44
Kingdom of Poland	1829	1 44
British Islands	1818–1821	1 55
Netherlands	1827–1828	1 38
Germany Proper	1825–1828	1 45
Prussia	1821–1826	1 39
Austrian Empire	1828	1 40
France	1825–1827	1 39
Switzerland	1827–1828	1 40
Portugal	1815–1819	1 40
Spain	1801–1826	1 40
Italy	1822–1828	1 30
Greece	1828	1 30
Turkey in Europe	1828	1 30
Northern Europe		1 44
Southern Europe		1 36
The whole of Europe		1 40

For an accurate description of the various mortality tables which have hitherto been published, the reader is referred to the excellent article on the subject, by Mr. Milne, in the *Ency. Britannica.*

MO'RTAR. (Dut. mortar.) In Architecture, a cement for the junction of stones and bricks, made of lime, sand, and water. In the composition of it stone lime is preferable to that burnt from chalk, and river to pit or road sand.

MORTAR. A short wide piece of ordnance for throwing shells, bombs, grape-shot, &c. It is the most ancient kind of cannon.

MORTAR. In Pharmacy, a vessel made either of iron, stone ware, or glass, &c., according to the use to which it is applied, in which substances are either pulverized or dissolved by means of a pestle. In fine chemical processes recourse is often had to mortars made of agate, flint, or porphyry.

MO'RTGAGE. In Law, a mortgage-deed is in effect a conveyance, by which a party grants his interest or a portion of it to another, with a condition that if a sum of money is paid by a stipulated day the grant shall be void. Thus the grantee has a conditional estate, whether of fee-simple or otherwise, according to the terms of the conveyance. During the continuance of this estate the mortgagor, though in possession, is in contemplation of law only tenant-at-will to the mortgagee; and on failure of payment the estate of the mortgagee would become absolute at law. But in equity the mortgagee's estate is subject to an *equity of redemption*, or right to redeem on the part of the mortgagor; and a mortgage is thus redeemable so long as the relation of debtor or creditor appears to subsist between the parties, and for twenty years after the last acknowledgment of that relation by the mortgagee, unless upon his application the right be previously foreclosed by a decree of the court.

MORTIER. (Fr.) The name given to a cap of state of great antiquity worn by the first kings of France, and the form of which is still preserved in the cap worn by the president *de la cour* of Paris.

MORTIFICA'TION. (Lat. mors, *death*, and facio, *I cause.*) Local death, gangrene. When any portion of the body loses its vitality, a process of separation takes place between it and the living parts that surround it; and when this happens in certain parts or organs it is necessarily fatal. The symptoms that attend mortification of the viscera are generally loss of pain, diminution of fever, small sinking pulse, hiccup, delirium, cold sweat, and fainting, which precedes death.

MORTIFICATION, in Scottish Law, is nearly synonymous with mortmain in English. By an act of 1587, land vested in the church was declared to be given for superstitious purposes, and to belong to the crown; and thus the spoliation of the richly endowed church of that country prior to the Reformation was finally legalized.

MO'RTISE (Fr. mortaise), in Architecture, is the junction of two pieces of wood or other material, the cavity cut in one piece being the receiving correspondent portion of the wood of the other, which is called a tenon.

MO'RTMAIN. In Law, an alienation of lands, tenements, or hereditaments, to any corporation, sole or aggregate, guild, or fraternity. The foundation of the statutes of mortmain is Magna Charta; by which it was rendered unlawful for any one to give his lands to a religious house, &c. in order to take them back again to hold of the same house; which was extended, by interpretation, so as to annul gifts of lands which religious houses did not give back to the donor to his own use, but kept in their own hands after taking. A great number of statutes were afterwards passed in order to restrict alienations to religious persons and houses, and various devices formed for the purpose of eluding them; of which the system of uses, which has become in some sort the foundation of our law of real property, was one. (*See* REAL PROPERTY, TRUST.) But during the whole of this time the king had the power of dispensing with the statutes of mortmain by granting licences of alienation; and this power was confirmed to the crown by stat. 7 & 8 W. 3. c. 37. Alienation to charitable uses are exempted from the statutes of mortmain; but they are subjected to particular forms and solemnities by the last mortmain act, 9 G. 2. c. 36. The term mortmain is derived from the Latin words mortua manus (*dead hand*), because the lands so alienated are said to fall into a dead hand; *i. e.* one incapable of performing the usual services required of tenants.

MO'RTUARY. In Law, a fee paid to the incumbent of a parish, by custom peculiar to some places, on the death of a parishioner. It appears to have been a very ancient usage to present the priest, on the solemnization of a funeral, with some personal chattel of the deceased, or a sum of money in lieu of it: under the various titles of pecunia sepulchralis, sedatium; in Saxon *soul-shot*, &c. It had become a legal custom as early as the reign of Henry III., when the reservation of a mortuary appears to have been essential to the validity of a testament of chattels. The amount was fixed by 21 H. 8. c. 6. according to an *ad valorem* taxation of the goods of the deceased. Mortuaries (where due by custom) are recoverable in the ecclesiastical courts; and it should appear, since the statute, at common law; although such actions have not hitherto been brought.

MO'RUS (Lat. *the mulberry tree; Celtic* mor, *black*), is a small genus of plants, containing some species valuable for their foliage, and others for their fruit. The latter is our mulberry tree, *Morus nigra*, whose well-known black juicy berries are a favourite autumn production; the former are *M. alba, philippensis*, and others, which constitute the best of all food for silkworms. The latter are found occasionally in plantations; but they are too tender to bear our climate well, and cannot be usefully cultivated even in the midland country of England.

MOSA'IC, or MUSAIC. (Gr. μουσαικον, *polished, elegant;* from μουσα, as being *fine or ingenious?*) In Painting, a species of representation of objects by means of very minute pieces of stones or pebbles of different colours, carefully inlaid upon a ground generally of metal. In St. Peter's at Rome are to be seen some works of this sort on a magnificent scale. This art was practised at a very early period, and was reintroduced to Italy by the Byzantine Greeks.

MOSA'IC GOLD. Bisulphuret of tin; a yellow flaky substance, sometimes employed in ornamental japan work. This term has lately been applied to a superior kind of brass, and to a yellow alloy of copper, zinc, and gold.

MOSA'IC WORK. In Architecture, the inlaying pavements, walls, &c. with small dies of different-coloured stones or glass, in regular figures, or to represent historical or other subjects.

MOSLEM. *See* MUSSULMAN.

MOSQUE (Arab. medsched.) A Mohammedan place of religious worship. The principal interior decoration of mosques consists in the lamps, which are numerous, and singularly disposed; the floor is covered with carpets: the direction of Mecca is denoted by a niche, or by a tablet inscribed with verses of the Koran, called the Kebla. The principal Arabian and Syrian mosques are most remarkable for their vast quadrangles, surrounded with numerous columns; those of the Turks for the elegance of their cupolas. The original places of worship of the Arabians were the temples dedicated to the religion of the different nations whom they subdued: such, for instance, as the temple of Jerusalem, the temple of Minerva at Athens, and innumerable others in Spain, Asia, and Egypt. It was not until they had consolidated their power that the Arabians devoted themselves to the cultivation of the arts, and gave any indication of that original architectural genius which afterwards displayed itself in the structure of mosques. At the entrance of almost every mosque there is a large court planted with bushy trees, in the centre of which, or under a vestibule paved with marble, are fountains for the prescribed ablutions of the Mussulmans; and to these courts is usually attached a small gallery, on which the apartments of the ministers of religion, &c. abut. But besides mosques for public worship there are others set apart for the instruction of young men in the science of legislation, and the doctrines of the Koran; and to this class belong the so called *royal* mosques, or *jamis*, of Constantinople. Most of these mosques have hospitals for poor, the sick, or deranged persons attached to them. Their revenues are often considerable, and are derived chiefly from endowments in landed property. The term *mosque* is found, with slight variation, in all European languages. The Turkish equivalent is meschil, which is supposed to be derived from the Arabic mesgiad, *a place of adoration;* and from this are derived respectively the Fr. mosquée, the Germ. moschee, the Span. mequita, the Ital. meschcta, and the Eng. mosque. *See* MINARET.

MO'SSES, in common language, are any minute,

small-leaved Cryptogamic plants. Thus club moss is a lycopodium; Iceland and reindeer mosses are lichens; and the numerous species of Jungermannia are all comprehended under the same term. But in systematical botany no plants are considered mosses except such as belong to the natural order *Bryaceæ* or *Musci*. Such plants are simple-leaved; without spiral vessels or stomates; with a distinct axis of growth; and with the spores or reproductive matter enclosed in cases, called sporangia or thecæ, covered by a cup or calyptra. The structure of the sporangia is as complex as that of the stems and leaves is simple. Each sporangium is closed by a lid or operculum; below which is a transverse membrane, closing up the urn left after the fall of the operculum. The edge of the urn is furnished with one or more rows of teeth, in all cases some multiple of 4; in the centre is a columella or column, and between the latter and the sides of the urn are the spores. It is not a little singular that such plants should have cases called staminidia, containing powdery matter; among which are found animalcules, not distinguishable from such as are called spermatic, and which swim about freely in water. None of the mosses are of any known use.

MOSS LAND. Land abounding in peat moss, but not so much saturated with water as to become peat bog, or morass.

MOSS-TROOPERS. In English and Scottish History those inhabitants of the borders of the respective countries who were banded together in clans and lived by rapine received this denomination, from the character of the country over which they "trooped" in their excursions. These banditti were little heard of after the union of the two crowns, but not absolutely suppressed until the union of the kingdoms a century afterwards.

MOTES, among the Anglo-Saxons, were public courts or conventions of the people assembled for municipal or legislative purposes. They were of various kinds; as Wittenagemote, Folkmote, Burgemote, &c. (See these separate articles.) *Moteer* was a customary service or payment at the mote or court of the lord, from which certain persons alone were exempted by charter or other privilege.

MOTE'T. (Ital. motetto.) In Music, a composition consisting of from one to eight parts, of a sacred character.

MO'THER OF PEARL (Fr. nacre de perles; Germ. perlen-mutter), is the hard, silvery, brilliant internal layer of several kinds of shells, particularly oysters, which is often variegated with changing purple and azure colours. The large oysters of the Indian seas alone secrete this coat of sufficient thickness to render their shells available to the purposes of manufactures. The genus of shell fish called *Pentadinæ* furnishes the finest pearls, as well as mother of pearl; it is found in greatest perfection round the coasts of Ceylon, near Ormus in the Persian Gulf, at Cape Comorin, and among some of the Australian seas. The brilliant hues of mother of pearl do not depend upon the nature of the substance, but upon its structure. The microscopic wrinkles or furrows which run across the surface of every slice act upon the reflected light in such a way as to produce the chromatic effect; for Sir David Brewster has shown that if we take, with very fine black wax, or with the fusible alloy of D'Arcet, an impression of mother of pearl, it will possess the iridescent appearance. Mother of pearl is very delicate to work; but it may be fashioned by saws, files, and drills, with the aid sometimes of a corrosive acid, such as the dilute sulphuric or muriatic; and it is polished by colcothar of vitriol. (*Ure's Dictionary of Arts, &c.*)

MO'THER WATER. A term applied by chemists to saline solutions from which crystals have been deposited, and which when poured off and re-evaporated furnish a second crop.

MO'TION. (Lat. motio.) In Mechanical Philosophy, motion is the change of place; that is, of the part of space which the body occupies, or in which it is extended. Motion is *real* or *absolute* when the moving body changes its place in absolute space; it is *relative* when the body changes its place only with relation to surrounding bodies; and it is *apparent* when the body changes its situation with respect to other bodies that appear to us to be at rest. All the phenomena of motion are derived by mathematical deductions from the three following laws of motion of Newton:—

1. A body must continue for ever in a state of rest, or of uniform motion in a straight line, if it be not disturbed by the action of an external cause.

2. Every change of motion produced by any external force is proportional to the force impressed, and in the direction of the straight line in which the force acts.

3. Action and reaction are equal and in contrary directions; that is, equal and contrary changes of motion are produced on bodies which mutually act on each other.

For the formulæ which express the relations between the moving force, the spaces passed over, and the times when bodies move in straight lines or curves, with uniform or accelerated velocities, see FORCE AND VELOCITY. For elementary illustrations of the above three laws, we refer to Maclaurin's Account of *Newton's Principia*.

MOTION. (Lat. motio.) In Painting and Sculpture, the change of place or position which from certain attitudes a figure seems to be making in its representation in a picture. It can be only implied from the attitude which prepares the animal for the given change, and differs from *action*, which see. Upon motion, in art, depends that life which seems to pervade a picture when executed by a master.

MOTION. In Music, the manner of beating the measure so as to hasten or retard the pronunciation of the words or notes.

MO'TION IN COURT. In Law, an occasional application to the court, by the parties or their counsel, for the purpose of obtaining some rule or order of court which becomes necessary in the progress of a cause. Motions are either of a criminal nature, as motions for an attachment for a misbehaviour; or of a civil nature. A motion in the courts of common law is either for a rule absolute, *i. e.* to take effect immediately; or it is for what is termed a rule nisi, or a rule to show cause—*i. e.* a rule to take effect, unless cause be shown against it by a certain day, when, if no cause be shown, the rule is made absolute on a second motion. Motions are accompanied by affidavits stating the facts on which they are grounded, and generally preceded by a notice to the opposite party.

MOTION, QUANTITY OF. This term is used by writers on mechanics to denote the product of the mass or moving body by the velocity. *See* MOMENTUM.

MOTIVE FORCE. The force which tends to produce motion. It is the same with momentum.

MO'TOR, MOVER. A term applied by anatomists to certain muscles, &c.

MO'TTO (Ital.), is used to signify a word or sentence added to a device; and when put upon a scroll it is commonly employed as an external ornament of coat armour. The use of mottos for this purpose is very ancient. The term motto is also applied as a sentence or quotation prefixed to any writing or publication.

MOULD. Soil composed of decayed vegetable matter in a state of minute division, more or less mixed with garden earth. The kinds of mould most in use in horticulture are leaf-mould, formed from the decayed leaves of trees; rich mould, formed of thoroughly decayed stable dung; heath mould, found on the surface of heath lands; and peat mould, formed of thoroughly decomposed peat. In general moulds are distinguished from soils by containing a much greater portion of vegetable matters than of earths.

MOULD. (Span. molde.) In Sculpture, the matrix or hollowed wrought form into which the liquid or plaster, wax or metal, is run in casting works of art.

MOU'LDING. (Fr. moule.) In Architecture, the members of an order, which are shaped into various curved or flat forms, of which there are eight sorts. The fillet, which is square in profile (1); the astragal (2);

the torus (3), being larger than the astragal; the scotia (4); the echinus (5), or quarter round; the inverted cyma, talon, or ogee (6); the cyma, cyma recta, or cymatium (7); and the cavetto or hollow (8).

MOULD LOFT. A large room in a dockyard in which the several parts of the ship are drawn out in their proper dimensions.

MOU'LTING. The fall of the plumage of birds. It may be either partial or total: the complete moult generally takes place annually; the partial moult occurs at the change of plumage to which some species of birds are subject at the breeding season. The moult is always accompanied by the development of a new plumage, which may be of a different colour from that which is lost. *See* INDUMENTUM.

MOU'NTAIN LIMESTONE. A series of limestone strata, the geological position of which is immediately below the coal measures, with which they also sometimes alternate. *See* GEOLOGY.

MOU'NTAIN MILK. A very soft spongy variety of carbonate of lime.

MOUNTAIN. (Lat. mons.) In Geography, the term applied to designate the principal elevations on the earth's surface. Mountains and hills, says Bakewell, are relative terms with respect to each other; the highest elevations being denominated mountains, and the lower hills. In the vicinity of Mont Blanc and Mont Rosa, which are more than 5000 yards high, the mountains in Cumberland and North Wales would be called hills; though Snowdon rises more than 1100 yards, and Skiddaw and Helvellyn more than 1000 above the level of the sea. In England, if hills rise abruptly, and are more than 400

yards above the surrounding country, they are generally called mountains. *See* GEOLOGY.

Arrangement of Mountains. — Mountains are seldom found insulated or detached: sometimes, though rarely, they exist in aggregate groups, branching from a common centre, and not externally connected; but most commonly they are extended in ranges or mountain chains, traversing extensive regions. A single continuous chain is of rare occurrence: in general a number of chains is associated; though there does not seem to be any predominating form of aggregation or direction, at least with reference to the whole surface of the globe. In some instances there is a principal or central chain, with secondary groups branching off from it; in others, several chains are associated, to no one of which the rest can be said to be subordinate; and in others again, as the Cordilleras, a series of chains succeed each other, all running in one constant direction. It has been surmised that the direction of the principal mountain chains is that of the line of greatest length of the continent or region to which they belong; but this idea, though rendered plausible by some remarkable instances, can scarcely be said to be borne out by the facts. In a very general view it may be stated that the predominating direction of the great mountain chains of the old world is from west to east; while those of America range from north to south. *See* GEOGRAPHY.

Another generalization, which seems to be liable to fewer exceptions, is, that mountain chains or ranges present the steepest acclivities on the sides nearest the sea. This arrangement is particularly observable on the shores of the Mediterranean: the mountains of Armenia present their precipitous sides to the Euxine, and those of Caucasus and Mozanderan to the Caspian. The western Ghauts face the Indian ocean; and the whole range of the Cordilleras, with their prolongation to the Arctic ocean, presents its escarpments to the great Pacific. On the hypothesis that the continents and mountain masses have been upheaved by a force acting in the interior of the earth, these peculiarities of configuration afford scope for curious speculation respecting the prodigious efficacy of the subterranean agencies through which the crust of the earth has assumed its actual form.

Altitude of Mountains. — On taking a general view of the surface of the earth, the elevation of the loftiest mountain chains, enormous as it appears to be, is insignificant in comparison of the dimensions of the globe. The radius of the earth is nearly 4000 miles; while the height of the highest peaks above the mean level scarcely exceeds 5 miles: the ratio is accordingly 1 to 800; so that on a 16-inch globe the corresponding inequality would only amount to the hundredth part of an inch. Mountains, however, exercise a very great influence on the climate of a country: and hence it is of great importance in geography to ascertain their altitude and configuration. The methods by which the measurement is effected have been explained under the term HEIGHTS, MEASUREMENT OF.

The following are the altitudes of a few of the most elevated peaks in the four quarters of the world. The most extensive list which we have seen is given in *Gehler's Physicalisches Lexicon*, art. "Höhenpunckte," where the authorities for the different measures are also stated.

Europe. — Mont Blanc, Alps, 15,781 ft.; Mont Rosa, 15,555 ft.; Ortler Spitze, Tyrol, 15,430 ft.; Jungfrauhorn, 13,720 ft.; St. Gothard Pass, 9,975 ft.; Hospice, Great St. Bernard, 8,040 ft.; Mont Perdu, Pyrenees, 11,283 ft.; Le Pic Blanc, do., 10,205 ft.; Monte Corno, Appenines, 9,523 ft.: Lomnitz, Peak of Carpathians, 8,640 ft.; Parnassus, 8,000 ft.; Mulahacen, Sierra Nevada, Spain, 11,673 ft.; Ætna, Sicily, 10,963 ft.; Sneehattan, Norway, 8,115 ft.; Snaefell, Iceland, 6,860 ft.; Helvellyn, England, 3,055 ft.; Ben Macdui, Scotland, 4,418 ft.; Macgillicuddy's Reeks, Ireland, 3,410.

Asia. — Dhawala-giri, Himalaya, 26,862 ft.; Jamautri, do., 25,500 ft.; Elburz, Caucasus, 18,500 ft.; Mouna Kaah, Sandwich Islands, 18,400 ft.; Demavend, Mazanderan, 14,700 ft.; Soomoonang, Thibet, 14,500 ft.; Ophir, Sumatra, 13,842 ft.; Italitzkoi, Altai, 10,735 ft.; Ararat, Armenia, 9,500 ft.; Lebanon, 9520 ft.; Sinai, 5,000 ft.; Tangai, Ural, 4,912 ft.

Africa. — Mountains of Geesh, 15,000 ft.; Peak of Teneriffe, 12,236 ft.; Atlas, 11,400 ft.; Niewveldt, Cape of Good Hope, 10,000 ft.; Gros Morne, Isle of Bourbon, 9,600 ft.; Trigo, Canaries, 7,400 ft.; Tuivo, Madeira, 5,162.

America. — Sorata, Bolivia, 25,000 ft.; Illimani, Peru, 24,450 ft.; Chimborazo, Andes, 21,440 ft.; Antisana, 19,150 ft.; Catopaxi, 18,890 ft.; Volcan de Popocateptl, Mexico, 17,716 ft.; Potosi, 16,000 ft.; Nevado de Mexico, 15,700 ft.; Lake of Titicaca, 12,000 ft.; City of Rio Bamba, 10,800 ft.; White Mountains, Massachusetts, 6,230 ft.

MOU'RNING, may be defined generally as an external indication or manifestation of grief for the death of a friend or relative. Certain usages in regard to mourning have been in force among all nations, barbarous and civilized, from the earliest ages; but except in the grief of which they are intended to be the symbol, no customs exhibit fewer marks of uniformity. Thus, the Chinese mourn in white; the Turks in blue or in violet; the Egyptians in yellow; the Ethiopians in grey. In ancient Rome and Lacedæmon the ladies mourned in white. In Eastern countries it was regarded as a peculiar mark of affliction to cut the hair; and at Rome, on the contrary, to let it grow. The Greeks adopted the Eastern practice, and bestrewed the tombs of those for whom they mourned with their hair. The peculiarities of the ancient Jews in time of mourning are well known; and the various customs of which so minute an account is contained in the Pentateuch are still maintained on these occasions by their descendants. From the commencement of the Christian era the general colour adopted for mourning throughout Europe has been, with very few exceptions, black. The kings of France mourn in violet. Tue duration of the period of mourning differs in different countries, but in all is usually regulated by the nearness of relationship between the survivors and the deceased. Thus in France the period prescribed by usage is, for a husband, one year and six weeks; for a father, mother, wife, or child, six months; for a grandchild four months and a half; for a brother or sister two months; for an uncle or aunt three weeks; for a cousin-german fifteen days, &c. The rules that determine the forms and duration of *court mourning* emanate from the sovereign, but these do not extend beyond the court; and though on the demise of the crown or a relation it is expected, in the language of the *Gazette*, that the people "put themselves into decent mourning," this is seldom generally complied with, except when the character of the deceased has been such as to secure wide popularity. (The art. "Deuil," in the *Encylopedié des Gens du Monde*, gives a very complete view of the chief modes of mourning in use in ancient and modern times.) *See* SEPULTURE, RITES OF.

MOUSE. (Lat. mus; probably from the Greek μυειν, *to hide.*) The pretty but annoying little Rodent quadruped which infests human dwellings and granaries is usually understood by this word; the other small species of the genus *Mus* being distinguished by some prefix, as harvest mouse, field mouse; and the larger species of the same genus being termed "rats." (For the generic characters of the mouse, see MUS.) The common mouse, like the rest of the genus, and indeed the whole of its order, is remarkable for its fecundity; it produces ordinarily five or six young ones at a birth, and this several times in the course of the year. In a fortnight the young are able to leave the mother and assume an independent existence, and these are soon again able to reproduce. The harvest mouse (*Mus messorius*) is the smallest of known mammals; the length of the head and body is two inches and a half. Its nest is beautifully and elaborately constructed of the panicles and leaves of three stems of the common reed interwoven together, and forming a roundish ball suspended on the living plants at a height of about five inches from the ground. The field mouse is about the size of the house mouse, but is distinguished by its larger eyes and ears. Many small mouse-like quadrupeds are commonly termed "mice" which really belong to a different genus, or even order; as the dormouse, the field vole, the shrew, &c.

MOUSE. In Naval Affairs, a hump or knot worked on a rope, to prevent a noose from slipping.

MOUTH. (Sax. muð.) In Architecture, the same as cavetto, which see.

MO'VEABLE FEASTS. Certain festivals held in commemoration of different events recorded in the Gospels and the Acts of the Apostles, and connected with the personal circumstances of Christ during the last year of his earthly life, and after his death. As they are reckoned backward and forward from his resurrection, and as the celebration of that day depends on the time of new moon, which varies at different times through the space of a month, these dependent festivals also vary in the same way. Easter is always the first Sunday after the first new moon after the 21st of March; and from this all the others are reckoned for each year.

MO'VEMENT The train of wheel work of a clock or watch. *See* HOROLOGY.

MOVEMENT. In Politics, an expression that has been adopted of late years into the political vocabulary of most European nations, signifying that party in a state whose principles consist in a restless endeavour to obtain such concessions in favour of popular rights as will ultimately place the chief functions of government in the hands of the people. It is opposed to the Conservative party, or the *parti de resistance*.

MOW. A mass of corn in the sheaf, built up in one end of the barn preparatory to being threshed.

MOW'ING. The act of cutting down grass, herbage, or corn with a scythe. Mown grass, or herbage, is either given to horses and cattle in a green state, or dried and

stacked for winter use. When corn or pulse are mown, they are dried and stacked till a convenient season occurs for separating the corn or pulse from the straw or haum by threshing.

MO'XA. A soft woolly substance made in Japan from the leaves of the *Artemisia Chinensis*, or Chinese mugworts. It is used as an actual cautery, by placing a small cone of it upon the skin and setting fire to it, when it burns down to the part and makes a sore, which is kept open if requisite.

MOYA. Mud poured out from volcanos.

MUCI'VORA. (Lat. mucus, *slime*, voro, *I devour*.) A name applied to a family of Dipterous insects, comprehending those which feed on the mucus or other juices of plants or of decomposing animal bodies.

MUCK, RUNNING A. A phrase which has been adopted into the English language to signify an indiscriminate attack upon friends and enemies; as in the well-known verse,

> Who runs a *muck*, and tilts at all he meets.

This expression is derived from the Javan word amok, which means *to kill*; the inhabitants of Java, and many other of the Asiatic islands, being remarkable for an irresistible phrenzy resulting from a desire of vengeance, which leads them to aim at indiscriminate destruction, and thus to subject themselves to be treated like wild beasts which it is impossible to take alive. These fits of desperation were long considered peculiar to the class of slaves in the islands above mentioned; but there are many instances on record where whole villages, and even armies, have under the influence of a *mok* devoted themselves to inevitable destruction to avenge an injury or an insult. The accounts of the wars of the Javans, says Raffles, in his *History of Java*, as well as of the Maláyus, abound with instances of warriors running *amok*; of combatants, giving up all idea of preserving their own lives, rushing on the enemy, committing indiscriminate slaughter, and never surrendering themselves alive. The cause of these fits of desperation has been attributed to an intemperate indulgence in opium-eating.

MU'COUS MEMBRANE. The membranous lining of the canals and cavities of the body which are exposed to the contact of air or other inorganic substances. The basis of this membrane is compact cellular tissue, not gelatinous or adipose, and having a peculiar cuticular covering, beset in some cases with abundant nervous papillæ, in others with the orifices of secretory glands.

MU'CUS. (Lat.) The secretion of the mucous membranes, the most characteristic of which is that from the nasal membrane. Mucus is viscid, and acquires apparent fluidity in water, without being actually dissolved; but gives a ropiness to it when present to a less amount than 1 per cent. With pure water of the temperature of 95°, this appearance ensues in a few hours; but if the apparent solution be filtered, the mucus remains upon the paper and gradually thickens. It may be repeatedly dried and moistened without material change of properties; it, however, becomes less transparent, yellow, and at length has a purulent appearance. When boiled in water it does not harden and shrink, but becomes tough, and on cooling is found to retain its former characters. When dried it is yellow and translucent; and subjected to distillation, it yields carbonate of ammonia and empyreumatic oil, and phosphate and carbonate of lime and carbonate of soda are found in the ash. It is soluble in dilute sulphuric acid, and blackened by the concentrated acid; it is not soluble in acetic acid, but yields but a trace of albumen. According to Henle, mucus consists of the scales of the epithelium which covers the open cavities of the body. This epithelium or cuticle consists of minute cells of various forms, which are continually wearing off and being renovated; it thus yields scales which mix with the watery secretion, and constitute mucus.

MU'DAR. The Indian name of *Calotropis gigantea*, a plant of the Asclepiadaceous order; a substance used medicinally in that country, with great effect in scrofulous cases, but not admitted into the Materia Medica of Europe. It gives its name to *mudarine*, a peculiar chemical principle, having the singular property of softening by cold and hardening by heat.

MUE'ZZIN, in Mohammedan countries, is the general appellation of those officers, or clerks of the mosques, whose duty it is to proclaim the ezam or summons to prayers, at the five canonical hours; viz. at dawn, noon, 4 o'clock P. M., sunset, and nightfall.

MUFFLE. An arched vessel with a flat bottom, in which substances may be exposed to a red heat without coming into contact with the fuel. *See* ASSAYING.

MU'FTI. The Turkish title of a doctor of the law of the Koran; derived from *fetvas*, a rescript or answer to a question of law addressed to the competent authority; which fetvas it is the province of the mufti to issue. The mufti of Constantinople, or Sheikh-ul-Islam, is the chief functionary of the Turkish church, and represents the sultan in spiritual matters, as the grand vizier does in temporal.

MUGGLETO'NIANS. A sect of Christians who sprung up in England in 1561, and derived their name from one Muggleton, a tailor, who, together with an associate called Reeves, gave themselves out for the two last and greatest prophets of Jesus Christ, and asserted that they had power to save or to ruin in a future state whomsoever they pleased. Notwithstanding the absurdity of their pretensions, they obtained many adherents; and the belief in their inspiration has been maintained, though by a comparatively insignificant number, from the period of their first promulgating their opinions down to the present time. A collection of the writings of Muggleton and Reeves, together with other Muggletonian tracts, was published in 3 vols. 4to. in 1832, in which the reader will find the singular doctrines of this sect fully, but, as appears to us, not very intelligibly set forth. In the religious controversy to which the promulgation of their doctrines gave rise, their chief opponents were the Quakers, and among these were George Fox and William Penn.

MU'GILOIDS. (Lat. mugil, *a mullet*.) A family of Acanthopterygian fishes in the system of Cuvier, characterized by having an almost cylindrical body covered with large scales, and furnished with two separate dorsals, the first of which has but four spinous rays. The mouth is either edentulous, or is provided with teeth of extremely minute size. This family includes the genera *Mugil*, *Tetragonurus*, and *Atherina*: it is included in the Cycloid order in the system of Agassiz.

MULA'TTO. A term in general use in American countries, in which there exists a mixed population of different races and colours, for the offspring of a union between a white and a negro.

In our West Indian possessions the offspring of a white and a mulatto is called a *quadroon*, or one quarter black; of a white and quadroon a *muster*, or one eighth black; of a white and muster a *mustafina*, or one sixteenth black; after which they are said to be *whitewashed*, and are considered as Europeans. On the other hand, the offspring of a mulatto and a negro is called a *cabre*; of a cabre and negro a *griffe*; and, generally speaking, after this there is no distinctive appellation but negro. All this is sufficiently simple; but in the Spanish and Portuguese colonial possessions, the intermixture of Europeans with negroes, mulattoes, &c., and these again with other classes, has given rise to a multiplicity of denominations sufficiently vague and indefinite even in these languages, but wholly untranslateable into English. It must be admitted, however, that great ingenuity has been displayed in tracing the amount of European and negro blood that flows in the veins of the mixed races, as the following list of terms (which might be considerably augmented) will prove: — Zambi, quatralvi, tresalvi, saltatras, coyote, zambaigi, cambusos, giveros, puchuelas, albarassados, barrinos, &c. All these again may be multiplied in arithmetical progression, thus forming a host of modifications, each, however, retaining more or less his original characteristics in proportion to the relation in which he stands to his original stock.

In Spain, the term Mulatto has been employed to designate persons having a tincture of Moorish blood.

MU'LBERRY. The so called paper mulberry is the *Broussonetia papyrifera*, and not a morus; its tenacious pliable inner bark furnishing a valuable material for the dress of the South Sea Islanders and Chinese. The yellow dye wood called fustick is the produce of another species of this genus, the *Broussonetia tinctoria*. *See* MORUS.

MU'LBERRY CA'LCULUS. An urinary concretion, consisting chiefly or entirely of oxalate of lime. Many of these calculi in form and colour somewhat resemble the fruit of the mulberry.

MULCH. Straw or litter half rotten. In Horticulture when this material is applied round the roots or stems of plants to protect them from the drought or from frost, they are said to be mulched.

MULL. A term used in Scotland almost synonymously with Cape, which see; and applied to various projecting portions of the island, as the Mull of Galloway, of Cantyre, &c.

MU'LLAS. The priests of Tartary are so called. They form one of the three grand classes into which the Tartars are divided; the other two being the *murzas* or nobility, and the peasantry. Their chief duty consists in reading the Koran; but their stock of knowledge is generally so scanty, that they are seldom able to interpret the Arabic in which the office of the mosque is performed. The village mullas are generally decently behaved and respectable men; "a little too much given to sell charms for the ague, but living for the most part among their neighbours a quiet and charitable life, the arbitrators as well as curates of their sequestered valleys; and frequently possessing, in addition to these weighty charges, the sinecure office of parish schoolmaster." (*Quart. Rev.* vol. xxix. p. 129.) The Tartar *mulla* and the Persian *mollah* (which see) have evidently a common origin; but their rank and offices are wholly distinct.

MU'LLET, in Heraldry, represents the rowel of a

spur. In English blazonry it is depicted of five points: in French of six. It is used as the filial distinction of the third son. *See* DIFFERENCE.

MULLET. The name of the fishes of the genus *Mugil*, which, in addition to the family characters of the Mugiloids, have the middle of the under jaw produced into an elevated angular point, adapted, when the mouth is closed, to a corresponding groove in the upper jaw; the number of the branchiostegous rays is six. Of this genus there are three British species; viz. the grey mullet (*Mugil capito*, Cuv.); the thick-lipped mullet (*Mugil chelo*, Cuv.); and the short mullet (*Mugil curtus*, Yarrell); of these the first species is the least rare. The red mullets (*Mullus surmuletus*, Cuv.; and *Mullus barbatus*, Linn.) belong to a different family of fishes: the former of these species was the fish so greatly esteemed by the ancient Romans, and for which such extravagant prices were given when it had attained an unusually large size.

MU'LLION, or MANNON. In Architecture, the upright post or bar dividing two lights in a window.

MULTA'NGULAR FIGURES, MULTILATERAL FIGURES, or POLYGONS. Rectilineal figures of more than four sides, and each specially denoted by the number of its angular points; as a pentagon, hexagon, decagon, &c., which have five, six, ten sides or angles respectively.

MU'LTIARTI'CULATE (Lat. multus; articulus, *a joint*), in Zoology, is applied to the antennæ of insects, and to the legs of Crustaceans and Cirripeds, when they are composed of a great number of joints; also to bivalve shells which have numerous teeth in the hinge.

MULTICARI'NATE (Lat. multus, carina, *a keel*), in Conchology, is applied to a shell which is traversed by many keel-like ridges; as the *Fusus multicarinatus*, *Terebratula multicarinata*.

MULTIDE'NTATE. (Lat. multus; dens, *a tooth*.) In Zoology, when a part is armed with many teeth or tooth-like processes. A family of Nereids is hence termed *Multidentatæ* by De Blainville, on account of the structure of their horny jaws.

MULTILO'CULAR. (Lat. multus; loculus, *a lodge*.) In Conchology, this term is applied to those shells which, like the nautilus, have their cavity divided into many chambers.

MULTINO'MIAL. (Lat. multus; nomen, *name*.) In Algebra, an expression consisting of several terms (more than two), which are connected by the signs of addition or subtraction, + or —. Sometimes it is called a polynomial; and in modern works, after the French writers, a *polynome*.

MULTINOMIAL THEOREM. A theorem discovered by Demoivre for forming the numeral co-efficients which arise in raising any multinomial to any given power without the trouble of actual involution. The binomial theorem of Newton is a particular case of this; viz. that in which the number of terms is only two.

MU'LTIPLE. (Lat. multiplex.) Any quantity which contains another an exact number of times without a remainder is a *multiple* of the latter, and the latter is a *submultiple* or part of the former.

MULTIPLE POINTS. In Analytical Geometry, when two or more branches of a curve pass through the same point it is called a multiple point.

MULTIPLE VALUES, in Algebra, signify symbols which fulfil the algebraical conditions of a problem when several different values are given them; as the roots of an equation, certain functions of an arc or angle, &c.

MU'LTIPLICA'ND, in Multiplication, is the number or quantity that is to be repeated the number of times denoted by the multiplier.

MULTIPLICA'TION. In Arithmetic, an abbreviated process by which, when a number is to be repeated several times, a result equal to the sum arising from all the repetitions is obtained. (*See* ARITHMETIC, and FRACTIONS.) A considerable abbreviation of this is effected by the use of logarithms (*see* LOGARITHMS); and other methods of shortening the work or lessening the degree of attention requisite in performing it have at different times been devised, as Napier's rods, and the logarithmic slide rule of Gunter. *See* NAPIER'S RODS.

MULTISPI'RAL. (Lat. multus; spira, *a spiral turn*.) In Conchology, this term is applied to those opercula of univalve shells which exhibit very numerous and narrow spiral coils round a submedian centre.

MULTISTRI'ATE. (Lat. multus; stria, *a streak*.) In Zoology, when an animal or part is marked with many streaks.

MULTIVA'LVE. (Lat. multus; valva, *a valve*.) In Conchology, when a shell consists of several calcareous pieces; as that of the chiton or barnacle.

MULTO'CA. The name given to the code of laws by which the Turkish empire is governed; consisting of the precepts contained in the Koran, the oral injunctions of Mohammed, and the decisions of the early caliphs and doctors. It relates to every subject of life, and comprises various matters appertaining to government, the sultan being the sole judge of its application to particular cases. (*See* SULTAN, VIZIR. See also *Edin. Review*, vol. x. p. 259.)

MULTU'NGULATE. (Lat. multus; ungula, *a hoof*.) In Mammalogy, when a quadruped has the hoof divided into more than two parts corresponding with three or more digits; as the elephant, rhinoceros, &c. Ray so denominated a family of hoofed quadrupeds corresponding with the *Polyschidæ* of Aristotle.

MU'MMIFORM. (Lat. mumia, *a mummy*; forma, *form*.) In Entomology, the nymphs of certain Lepidoptera are so called which resemble an Egyptian mummy.

MU'MMY. (Arab. mumia; from mum, *wax*.) The name given to the dead bodies of men or animals which are by any means preserved in a dry state from the process of putrefaction. Mummies have usually been divided into two classes — natural and artificial; the former arising from peculiar conditions of soil and atmosphere, which permit the drying of the animal tissues to be effected with such rapidity that the body is preserved; the latter embracing the various means that have been employed from the earliest ages to preserve dead bodies from corruption. Of the former or natural class of mummies some well-known instances are to be found in the vaults of several Continental churches, particularly at Strasburg, Toulouse, and Bordeaux.

The *art* of embalming owes its origin to the extreme veneration with which the ancient Egyptians regarded the corpses of their relatives, and was practised with such success that at the lapse of 3000 years the mummies found in the numerous catacombs of Egypt are still objects of admiration. But it was not to the dead bodies of the human species alone that the ancient Egyptians restricted their reverence; they practised embalming also on all the animals which their religion held sacred, and of these upwards of fifty different species have been found embalmed.

The art of embalming was practised also to a considerable extent by the ancient Jews, Greeks, and Romans, though it never attained such celebrity or perfection among them as among the people from whom it was borrowed. It was also adopted as a national custom by the Guanches, the ancient inhabitants of the Canary Islands; a full account of which is to be found in the *Essai sur les Isles Fortunées*, by M. Bory de St. Vincent.

The account which Herodotus has left us of the Egyptian process of embalming is so minute, and has besides been so amply confirmed in the most essential particulars, not only by the subsequent writers of antiquity, but in still more recent times (see the *Memoir* of M. de Rouyer), that we cannot refrain from embodying it in our pages. There are, says he, persons resident in Egypt who make this art their profession. When a dead body is brought to them, they show the bearers three wooden models of mummies imitated in painting, the most elaborate of which are said to be of him (Osiris) whose name I do not think it right to mention on this occasion. The second which they show is simpler and less expensive; and the third is the cheapest of all. They then demand of the bearers which model they wish to be adopted; and the latter having decided upon the price, depart. The most expensive preparation is as follows: — First they extract the brain through the nostrils by means of a hooked iron instrument, — partly by pulling it out, and partly by the infusion of drugs. They then with a sharp Æthiopian stone make an incision in the side in order to extract all the viscera, which they wash with palm wine and purify with pulverized perfumes. Having next filled the belly with pure ground myrrh, cassia, and all other odoriferous herbs except frankincense, they sow it up; and rubbing the whole corpse with natron, bury it for 70 days, — a longer period not being admissible. At the expiration of the 70 days they wrap the whole corpse in bandages of fine linen, and smear it all over with gum, which the Egyptians are in the habit of using instead of glue. The friends of the deceased, on again receiving the body, have a wooden case made in the form of a human figure, in which they place it; and having shut it up, deposit it in a sepulchral building, setting it upright against the wall.

For those again who, on account of the great expense of this mode of embalming, adopt the middle course, the bodies are thus prepared: — They fill all the intestines with cedar oil, without either cutting into the body or extracting the viscera; and, taking means to prevent the egress of the injected liquid, they salt the body for the prescribed number of days. The cedar oil is then taken out; and such is the power with which it operates that it brings with it the bowels and all the viscera in a state of dissolution. The natron also destroys the flesh of the body, leaving only the skin and the bones. The body is then returned.

The third mode of embalming is that practised on the poor. In this case they inject into the body a mixture of salt and water, wrap it up in natron for 70 days, and then deliver it to the relatives. (*Herod.* b. 2. c. 186.)

It was long a matter of uncertainty what became of the intestines after they had been removed from the body of those embalmed according to the first process. Porphyry and Plutarch have both asserted that they were thrown into the Nile; but modern discoveries in the tombs leave no doubt of the fact that they were embalmed separately, and deposited in four vases in the coffin. (See *Sir G. Wilkinson's Manners and Customs of the Ancient Egyptians*, vol. ii. p. 467. 2d Series.)

Diodorus mentions three different classes of persons who assisted in preparing the body for the funeral: the scribe, who regulated the incision in the side; the *paraschistes* *, or cutter; and the embalmers. To these may be added the undertakers, who wrapped the body in bandages, and who had workmen in their employment to make the cases in which it was deposited. Many different trades and branches of art were constantly called upon to supply the undertakers with those things required for funereal purposes: as the painters of mummy cases; those who made images of stone, porcelain, wood, and other materials; the manufacturers of alabaster, earthenware, and bronze vases; those who worked in ivory; the leather cutters, and many others.

With regard to the question, when the custom of embalming the body ceased in Egypt, some are of opinion that it ceased at an early time, when Egypt became a Roman province. But this has been fully disproved by modern discoveries; and it not only appears that the early Christians embalmed their dead, but, according to St. Augustine, mummies were made in his time, at the end of the 5th century. The origin of this opinion is perhaps to be sought for in the circumstance that at the period of the Roman invasion of Egypt the custom may not have been universal; and Sir G. Wilkinson maintains that it in all probability gradually fell into disuse, rather than that it was suddenly abandoned from any accidental cause connected with change of custom, or from religious scruple.

Since the commencement of the present century, the attention of the learned in the chief countries of Europe has been particularly directed to the subject of embalming the dead; and the researches of numerous travellers from Belzoni downwards to Sir G. Wilkinson, aided by the scientific manipulations of Pettigrew and others, have cleared up many points that were formerly obscure in reference to this art, which was so general in ancient, though wholly unknown in modern Egypt. The following observations, borrowed from *Dr. Nuttall's Classical and Archæological Dictionary, &c.*, will at once exhibit briefly the state in which the mummies are found at the present day, and serve as an appropriate commentary on the description of the process of embalming, as detailed above. The practice of embalming upon the immense scale of the population of a country such as Egypt involves a problem of the highest interest. If to those numberless pits and catacombs of human corpses are also conjoined the mummies of the ibis, dog, ape, cat, and crocodile; the bull Mnevis, Apis, and Isis; the ram, the fox, and horned asp; in short, of every reptile of the land, — we are lost in surprise and amazement how such a process could be established; and if by resins, drugs, or spices, from whence such profuse quantities could be procured and supplied. These bodies, also, are often enveloped in silks and bandages of stained linen of surprising brightness (and sometimes measuring 1000 yards in length —*Sir G. Wilkinson*); they are ornamented with gilding as fresh as when first laid on; with pieces of coloured glass imitative of the finest gems, evidencing their knowledge of staining and cutting them in a manner which merits notice, as well as their enamels also. All these ornaments found around the mummies are highly preserved, and, as well as the sycamore chests, resist all the injuries of time, and subsist fresh and perfect for the examination of the curious. They usually have the Nubian cast of countenance; the outline figure traced in black; and the colours, four in number — blue, red, yellow, and green — laid on without any mixture of shading, but altogether forming a composition of very considerable interest. These chests usually have within them small scarabæi, or the idols of Isis and other deities, in clay and coloured glass and beautiful enamels. One scarabeus, mentioned in *Greaves's Pyramidographia*, was of magnet, which, although 3000 years since it was taken from the rock, its natural bed, still retained its attractive magnetic virtue. The recent discoveries of M. Belzoni add also to our stock of information upon the articles of the wrappers, and prove in this also the science and the labour of their embalming, by evincing that there were distinct modes of preservation and of envelopes for every caste, — that of the priesthood particularly, with a scrupulosity of minute detail that astonishes and marks their high privileges. Upon examining mummies that have been brought to Europe, a decided similarity of ornament is observable: the better-conditioned being covered with glass ornaments, cut as precious stones, and disposed with the same arrangement of colours, and offering the same construction as the other mummies that are painted; testifying that the ornaments which were costly were preserved for principal personages, while the inferior classes contented themselves with tracing the decorations in paintings.

It has been frequently maintained that the doctrine of metempsychosis formed part of the ancient Egyptian creed; but it would seem that the practice of embalming the dead is wholly irreconcileable with such a doctrine. Others have explained this Egyptian usage as if it proceeded from a belief in materialism; but it can surely never be argued that unbelievers in the immortality of the soul would be most anxious to guard against the dissolution of the body. On the contrary, as Schlegel has well observed, this usage seems rather to set forth an indistinct feeling that this apparently dead matter is still important, — some mistaken and imperfect presentiment that the bond between the soul and matter is not altogether dissolved, and shall yet one day be restored, — and that even this matter shall have its portion in immortality, and be again animated and awakened.

MUMPS. This term is generally applied to inflammation of the parotid glands. It is seldom attended by fever or constitutional symptoms, but is occasionally translated to other glandular parts. A gentle dose of physic, and the application of a piece of flannel dipped in warm salt water or in solution of acetate of ammonia, is generally all the treatment required. From the way in which this complaint sometimes spreads in families or schools, there is some reason to believe it to be contagious or infectious.

MU'NDIC. A Cornish name for iron pyrites.

MUNDI'FICANT. (Lat. mundare, *to cleanse*.) A term applied in old pharmacy to certain healing and cleansing ointments and plasters.

MUNI'CIPAL, MUNICIPALITY. The word *municeps*, in the language of early Roman jurisprudence, signified a person capable of holding an office or dignity (from munus or munium, *an office*, and capio, *I take*). It was appropriated in its more particular meaning to those who, by the constitution of Rome, were admissible to certain privileges and honours, but not to the right of suffrage or magistracy, in consequence of not being full citizens. These were the strangers who in various ways became incorporated with the Roman people without acquiring the right of citizenship. The jurisconsult Paulus (as cited by Festus) notices three sorts of municipes:—1. Free strangers settled in Rome; 2. Citizens of commonwealths which became absorbed in that of Rome by conquest or submission (quarum civitas universa in civitatem Romanam venit); such were Aricia, Cere, Anagnia; 3. Citizens of allied commonwealths, who retained their citizenship at home while at the same time they became municipes of Rome: such were Tibur, Pisa, Arpinum. It is plain that this last is the sense in which the citizen of one state was said to be municeps of another. Towns of the last two descriptions (if the passage of Paulus is correctly understood) were probably comprehended by the Romans under the title of *municipia*; *i.e.* towns which possessed their own rights, and the burgesses of which were also municipes of Rome. Such burgesses often acquired full Roman citizenship and even dignity, but seem to have been always (in the republican times) regarded as of recent and comparatively ignoble franchise: as in the passage of Juvenal respecting Cicero (ignobilis et modo Romæ municipalis eques); *i.e.* one coming from the municipium of Arpinum. By later writers, municipia are sometimes confounded with colonies. The word municipal and its derivatives have passed into modern usage in two different senses: 1. The local government of a small district, especially of a town, and particularly if elective, is termed a municipality: such are municipal corporations in England; 2. Every Latin municipium had its own customary law (*jus municipale*). Hence with later jurists municipal law came to signify the law of particular towns, districts, and provinces. In this latter sense the customs of the French cities and provinces were called municipal laws. And among modern publicists the word has received a still greater extension; the positive law of a country (in opposition both to natural or moral law and to the law of nations) being often called its municipal law. The same term is also sometimes used rather vaguely in contradistinction to the constitutional or political law of a state; as where crimes are divided into offences against the state and municipal offences.

MU'NIMENTS. A common name, in legal phraseology, for deeds, charters, &c., chiefly those belonging to public bodies: great ecclesiastical corporations have generally a "muniment-room" in which these are kept.

* The office of *paraschistes*, or dissector, was held in infamy. "As soon," says Diodorus, "as the paraschistes has made his incision, he runs away, being pursued by those who are present, who throw stones at him amidst bitter execrations, as if to cast upon him all the odium of this necessary act." For the Egyptians look upon every one who has offered violence to, or inflicted a wound or any other injury upon a human body, to be hateful; but the embalmers, on the contrary, are held in the greatest consideration and respect, being the associates of the priests, and permitted free access to the temples as sacred persons.

Derived from Lat. munio, *I defend;* because, as it is said, these evidences serve to defend the title.

MURÆ'NOIDS. (Lat. muræna, *a species of eel.*) The name of a family of Apodal fishes, including the true eels (*Anguilla*), and the eels without pectoral fins (*Muræna*). The fishes of the latter genus are more voracious, and have their jaws armed with more formidable teeth than the *Anguillæ*. One species (*Muræna Helena*) was much esteemed by the ancients, who fattened it in ponds expressly constructed for the purpose. The history of Vædius Pollio, who caused his transgressing slaves to be flung into these ponds as food for the *Murænæ*, is well known.

MU'RAL ARC, or ARCH (Lat. murus, *a wall*), is a segment of a large circle fixed in the meridian against the wall of an observatory, for the measurement of the meridian altitudes or zenith distances of the heavenly bodies.

MU'RAL CIRCLE, MURAL QUADRANT, in Astronomy, is an instrument, generally of a large size, attached to a stone wall or pier of solid masonry, and fixed in the meridian for the purpose of measuring the distances of stars from the pole or the zenith. The first mural quadrant, or rather arch, used at Greenwich, was erected by Flamsteed in 1689, and divided by Abraham Sharp. There are still two quadrants in the Observatory, each about eight feet radius: one of them was erected by Graham in 1725, for the observations of Halley, and was redivided by Bird in 1753; the other was constructed by Bird in 1750, and is the instrument with which Bradley and Maskelyne made their most important observations. Experience having shown that entire circles are susceptible of much more accurate division, and much less liable to derangement than quadrants, a mural circle was constructed by Troughton, and placed in the Observatory in 1812. Since that time the advantages of this construction have been fully appreciated; and a mural circle is now regarded as the principal fixed instrument in all the great public observatories.

Troughton's mural circle is six feet in diameter. It is formed of brass, and fixed by means of sixteen conical radii, concentric to and at right angles with a conical axis nearly four feet long, seven inches in diameter at the extremity at which the circle is fixed, but only half as much at the other extremity. The axis rests and turns in two collars, one towards each end of the cone, fixed at the front and back of a stone pier about four feet in depth. The degrees are cut into five spaces, on a narrow ring of white metal composed of gold and palladium. The divisions are read by six micrometers, placed at equal distances round the circle, and securely fixed to the stone pier. The telescope is fixed at right angles to an axis which works within the conical axis of the circle. It consequently moves in the plane of the circle, and can be clamped in any position, so that the readings may be made on different parts of the circle. In order that the circle may move easily round its axis, and that the lower side of the front socket may be relieved from the load of the instrument, two large friction wheels are suspended in front of the pier from the arms of two levers, which, by means of counterpoises, may be made to support the whole or any part of the weight. The details of construction, however, admit of being varied in many different ways.

The use of the mural circle is to measure angular distances in the meridian. The axis must therefore be placed exactly horizontal, and the plane of the circle vertical and in the meridian, and the line of sight at right angles to the axis and parallel to the plane of the circle. Small errors, however, in the adjustments, scarcely affect the results. The advantages of the mural above all other astronomical circles consist in the permanence of the microscopes, and the facilities for observing stars by reflection. (For a detailed description of this instrument see *Pearson's Practical Astronomy;* also *Dr. Robinson's Description of the Mural Circle of the Armagh Observatory*, in vol. ix. of the *Memoirs of the Royal Astron. Society.*)

MU'RCHISONITE. A variety of crystallized felspar found in the new red sandstone near Exeter: its component parts are silica 686; potash 148; alumina 166: so called from its discoverer, Mr. Murchison.

MURDER, in the English law, is defined to be the killing any person under the king's peace, with malice prepense or aforethought, either express or implied by law. The word is of the same origin with the German *mord*, Fr. *meurtre;* in law Latin, *murdrare*, — to which word, in an indictment, an exception was taken by a prisoner in the reign of W. 3. as not being of good Latinity, which was overruled with contempt. The malice prepense is the chief characteristic which distinguishes murder from other species of homicide; and it is the great office of the jury to determine whether or not such malice has been shown: either express, as evinced by outward circumstances; or *implied*, as where one deliberately kills another without provocation the law implies malice. Malice is also *implied* where persons having authority to arrest or imprison using the proper means for that purpose are resisted in so doing, and killed, which offence is murder. Killing in the prosecution of an unlawful act, when the act is done deliberately and with intention of mischief, either indiscriminately or to particular individuals, is likewise murder, whether or not there was a premeditated design of killing the individual slain. So where particular malice against an individual is wreaked, by mistake, against another. Whenever, also, death ensues on an unlawful act done in prosecution of a *felonious* intention, it is murder; as where a man is killed by a shot discharged at an animal with intent to kill and steal it; or where the intent is only to do some great bodily harm, and death ensues. When several assemble to commit a breach of the peace forcefully, and happen to kill a man in the prosecution of such intention, they are all guilty of murder. In some cases, also, murder may be the consequence of a lawful act criminally or improperly performed, as by duress in a gaol.

The execution, in cases of murder, by 25 G. 2. c. 37., was to take place the next day but one after sentence, unless staid by the discretion of the judge; with an exception for Sunday, by 9 G. 4. c. 31.: and it was usual to sentence on Friday, in order that the Sunday might intervene before execution. But by 6 & 7 W. 4. c. 30. the time before execution was made the same as in other capital offences. It happened, at a trial for murder at the Devonshire assizes, only a few days after the passing of this act, when two men were convicted, that during the interval which elapsed sufficient doubt was raised as to the identity of one of the prisoners to prevent the execution.

By the French code pénal of 1810, the several kinds of homicide are accurately defined; and the crimes of "assassinat, parricide, infanticide, and empoisonnement," are capital. But the power given to the jury by the code of 1808, of pronouncing *under what circumstances* a criminal act has been committed, materially modifies the severity of the law. If extenuating circumstances are found by the jury, the punishment is diminished.

MU'REX. (Lat. murex, *a shell-fish.*) A name applied by Linnæus to a genus of the Vermes Testacea having a univalve spiral shell, with an oval aperture ending in an entire, straight, or slightly ascending canal. The Mollusks thus characterized form a family (*Muricidæ*, or rock-shells) in the Buccinoid tribe of Pectinibranchiate Gastropods of the system of Cuvier, and include the following genera: — *Murex* proper, *Brontis*, Montf.; *Typhis*, Montf.; *Chicoracea*, Montf.; *Aquilla*, Montf; *Lotorium*, Mart.; *Tritonium*, Montf; *Trophona*, Montf.; *Ranella*, Lam.; *Apolles*, Montf.; *Fusus*, Lam.; *Lathira*, Mart.; *Struthiolaria*, Lam.; *Pleurotoma*, Lam.; *Clavatula*, Lam.; *Pyrula*, Lam.; *Fulgur*, Montf.; *Fasciolaria*, Lam.; *Turbinella*, Lam.

MU'RIACITE. An anhydrous sulphate of lime, containing a little common salt.

MURIA'TIC ACID, or HYDROCHLORIC ACID. This acid was originally discovered by Glauber, and called by him *spirit of salt.* In its pure or gaseous form it was first obtained by Priestley in 1774; and its true composition was shown by Davy in 1809, who proved it to be a compound of hydrogen and chlorine; hence it has been termed *hydrochloric acid.* Muriatic acid gas is procured by acting upon common salt (which is a chloride of sodium) by concentrated sulphuric acid: the water of the acid is decomposed, and its hydrogen combines with the chlorine of the salt to form muriatic acid; whilst the oxygen is transferred to the sodium, which is thus converted into soda, and this unites to the sulphuric acid to form sulphate of soda. 60 parts of common salt, and 49 parts of concentrated sulphuric acid, afford, by this mutual action, 37 parts of muriatic acid, and 72 of sulphate of soda. Muriatic acid gas may also be formed by passing an electric spark through a mixture of equal volumes of chlorine and hydrogen; or by exposing such mixture to the sun's rays, or inflaming them by a taper, they burn with explosion, and form a volume of muriatic acid equal to the united volumes of the gases. As the specific gravity of hydrogen is to that of chlorine as 1 to 36, the specific gravity of the resulting muriatic acid gas compared with hydrogen will be 18·5, and 100 cubic inches of it will weigh 39·3 grains. Muriatic acid gas is rendered liquid under a pressure of 40 atmospheres of the temperature of 50°; it extinguishes flame, and is intensely sour, powerfully reddening vegetable blues. Water absorbs it with much violence, taking up about 480 times its volume. This is the state in which muriatic acid is generally used. Its specific gravity is about 1·19, and it is commonly obtained by distilling a mixture of equal weights of salt, sulphuric acid, and water. When muriatic acid acts upon metallic oxides, it generally happens that a mutual decomposition of the oxide and acid ensues; the oxygen of the oxide unites to the hydrogen of the acid to form water, and the metal to the chlorine to form a metallic chloride. Thus it is that soda and muriatic acid form a chloride of sodium or common salt. The most effective test of the presence of muriatic acid is nitrate of silver, which forms an insoluble chloride

of silver in all solutions containing muriatic acid or muriates.

MU'RICATE. (Lat. muricatus, *thorny.*) In Zoology, where a surface is armed with short, but not close-set cones, having a sharp apex.

MURI'DÆ. (Lat. mus, *a mouse.*) The family of Rodents of which the genus *Mus* is the type: by some naturalists it is restricted to the genera *Mus*, *Hesperomys*, *Dendromys*, *Gerbillus*, *Hydromys*, *Hapalotis*, and *Pseudomys*; by other naturalists it is extended to include the *Jerboidæ*, *Myoxidæ*, and *Castoridæ*.

MU'RINES. (Lat. mus, *a mouse.*) The name of a tribe of Rodent quadrupeds, of which the genus *Mus* is the type: it includes the families *Muridæ*, *Aroicolidæ*, and *Sciuridæ*, and is the most widely distributed of all the Rodent tribes.

MURRA'IN (Fr.), is the popular term of a malignant epizootic influenza to which cattle are subject, and which has at various times made terrible havoc among them. It appears to have been long known; and, from the accounts handed down, does not seem to have changed its characters materially.

This disease extensively raged on the Continent from 1710 to 1746 (Lancisi, *Disputatio Historica de Bovilla Peste*); and serious visitations of the malady were also witnessed during the years 1730 and 1731, and from 1744 to 1746: at that time many written descriptions were produced of this pest, among which the work of Sauvages, the celebrated professor of medicine at Montpelier, stands pre-eminent. It produced, in 1757, an extreme fatality among the cattle of this country; an account of which was published in an excellent work by Dr. Layard, a physician of London.

This disease, as it is met with in England, may be characterized as an extremely malignant inflammatory œdema, attacking, and indeed confining itself for the most part to one of the hind quarters of the animal. It is most common in the seasons of spring and autumn, and affects principally young cows. The most prominent features are tumefaction and a discolouring of the side affected, with consequent lameness and inability to move; a peculiar emphysema of different parts of the body, but particularly over the region of the spine; and all the symptoms of putrid fever present in diseases of a typhoid character. It speedily runs on to gangrene, and few animals survive an attack of this kind more than ten or a dozen hours.

Although the English murrain is somewhat modified in its virulence by season, locality, and the condition of the sufferer, it is nevertheless generally looked upon as incurable. When, however, remedial measures are had recourse to, extensive scarification, or rather incisions of the affected side, fomentations, and purgatives are most likely to effect the desired object.

It may be necessary also to remark, that this malady is known to farmers and others in the different counties of England by a variety of terms, none of which are either elegant or expressive; and, on the other hand, that diseases different altogether from the one under consideration have received the same name: indeed the word murrain is often used to denote any epizootic affection in cattle. The one just described may, however, be looked upon as the true murrain of this country.

The murrain which broke out in England about two years ago, and has ever since committed such havoc among the cattle, is travelling steadily northwards; but the disease has lost much of its original virulence, as almost always happens in the case of epidemics travelling from one country to another. Accidental circumstances aggravate the complaint, but in a general way it runs its course now in a few days; and to all appearance, condition lessened, or "taking-on" stayed, exceeds not from a fortnight to three weeks. Much depends upon the condition of the animal, and in numerous instances the distemper touches rather than skaithes. The doctoring process has been generally discontinued; and the best of all recipes is the warmth communicated by sheltered fields or sheds, rest, and the absence of disturbing influences.

The prevention of this disease is even perhaps more important than the medical treatment, and consists in allowing a free access of air to all the buildings, stalls, &c., with daily fumigation of them by chlorine or chloride of lime. Care should be taken to examine three or four times a day the cattle on every farm, so as to remove as speedily as possible the healthy ones from those that are affected.

MU'RRHINE. (Lat. murrhina vasa, Gr. μοῤῥινος.) Murrhine vases were a species of ware often mentioned by writers of the Roman empire, the material of which has been much disputed by modern antiquaries. They came from the East, and, according to Pliny, were made of some precious stone found chiefly in Parthia; but some have conjectured that this was an erroneous opinion prevalent among the Romans, and that they were in reality of porcelain, of which the manufacture was unknown to the western nations. (See *Plin. Hist. Nat.* l. 37.; and a memoir in the 43d vol. of the *Mem. de l'Ac. des Inscr.*; and *Maurice's Indian Antiquities*, vol. vii.)

MU'RRY, or SANGUINE. In Heraldry, a dark red; one of the colours or tinctures employed in blazonry. It is expressed in engraving by opposite diagonal lines crossing each other: reckoned a dishonourable colour; rarely to be met with in English coats of arms.

MU'RZAS. The name given to the hereditary nobility of the Tartars, or, more strictly perhaps, to the second class of their nobility; the first or principal class being designated beys. This titular appellation is also sometimes conferred on the descendants of public officers; but the latter are looked upon as upstarts by the older nobility, and regarded as an inferior race. The Murzas have from the earliest ages been distinguished for their bold and refractory character; and the peculiar privileges they formerly possessed supplied them with the means of giving effect to their turbulent dispositions. Since the conquest of Tartary, they have sunk into comparative insignificance; though many of them retain a large share of their former property, and have considerable influence among their own countrymen. (See *Quart. Rev.* vol. xxix. p. 128.) The Tartar *murza* is evidently of the same origin with the Persian *mirza*; with which, however, it must not be confounded. *See* MIRZA.

MUSA'CEÆ (Musa, one of the genera), constitute a small but very important natural order of plants, related to the orders yielding ginger, arrow-root, and similar substances; but differing in having several stamens instead of one only. The plantain (*Musa sapientum*), the most valuable product of the vegetable kingdom in hot countries, in consequence of the abundance of nutritious food yielded by its fruit, and the application of its leaves to the purposes of thatching, and of thread obtained from its petioles in the manufacture of the finest muslins, is the representative of the order. Another species is the *Musa paradisiaca*, or banana; and the singular plants called Strelitzias, with their orange and blue flowers, are also members of *Musaceæ*.

MU'SCA. (Lat. *a fly.*) A Linnæan genus of Dipterous insects, now expanded into a family (*Muscidæ*) of the fifth tribe (*Athericera*), of the order *Diptera* in Latreille's system. It is distinguished by a proboscis always very apparent, membranous, and bilabiate, generally bearing two palpi, and capable of being entirely withdrawn into the oral cavity; and a sucker of two pieces. The antennæ always terminate in a plate with a lateral setæ. The *Muscidæ* are divided into the subfamilies *Creophilæ*, which includes the meat-fly (*Musca vomitoria*), and the common house fly (*Musca domestica*); the *Anthornyzæ*, the *Hydrornyzæ*, the *Scatornyzæ*, the *Dolichocera*, the *Leptopoditæ*, the *Caprornyzæ*, the *Gymnornyzæ*, and the *Hypocera*.

MU'SCHEL KALK (German), signifies shell-limestone. This name is applied by some English geologists to a limestone formation belonging to the red sandstone group: it has not yet been found in England.

MUSCI. *See* MOSSES.

MUSCI'CAPA. (Lat. musca, *a fly*; capio, *I take.*) A genus of Dentirostral Passerine birds, characterized by a depressed beak, furnished with hairs at its base, and with the point more or less hooked and emarginate. The genus is now split into various subgenera; as *Tyrannus*, *Gymnocephalus*, *Muscipeta*, and *Muscicapa* proper, &c., included in the family name of *Muscicapidæ*. Their general habits are cruel and predatory, like those of the shrikes; and, according to their size and strength, they live on small birds or insects. The smallest and weakest of the *Muscicapidæ* gradually approach the form of the wagtails.

MUSCI'DÆ. The family of Dipterous insects, of which the fly (*Musca*) is the type.

MUSCIFO'RMES. (Lat. musca, *a fly*; forma, *form.*) The name of a tribe of *Tipulidæ*, or crane-flies, comprehending those which have a stout body and short legs, resembling the common flies.

MU'SCLE BAND. In Coal-mines, the black shale containing embedded muscle shells.

MU'SCLE. (Lat. musculus, diminutive of mus, *a mouse*, from its resemblance to a flayed mouse.) Fleshy fibres susceptible of contractions and relaxations. Some of the muscles are obedient to the will, and therefore called *voluntary*; others, such as the heart, are independent of the will, or *involuntary*; and others, as the diaphragm and muscles of respiration generally, have a *mixed* action, being to a certain extent only dependent upon the will. Muscles are aggregates of minute muscular fibres, which appear to be composed of small globules; but we are, in fact, ignorant of the ultimate structure of the muscles, and of the causes on which their wonderful powers depend. They are enveloped in and penetrated by cellular membrane, and abundantly supplied by nerves, blood-vessels, and lymphatics.

Their principal constituent or proximate elementary structure consists of albumen, besides which gelatin and fat are derived from their cellular membrane; and hæmatosin, osmazome, and other constituents of the blood are

also found in them: they therefore constitute the most nutritious species of animal food. *See* ALBUMEN and GELATIN.

All the muscles are under the immediate influence of the brain and nerves; and consequently when this influence is abstracted, as by the division of the nervous trunks by which they are supplied, the powers and functions of the muscles, whether voluntary or involuntary, are in the first instance disturbed, and afterwards cease altogether. Electricity is capable to a certain extent of recalling the action of the muscles, provided it be applied before rigidity ensues; hence the supposed identity of that power of matter and certain properties of the nerves. The arrangement of the fibres of muscles is infinitely various, and adapted to the particular purposes which each has to fulfil. In the voluntary muscles the fibres are generally parallel, or nearly so; but in the involuntary muscles they are more or less interwoven and interlaced. When muscles contract, they become shorter, harder, and thicker, and their bundles of fibres are thrown into undulated lines, with a tremulous or vibratory motion, most rapid where the contraction is most powerful, and producing a distinct sound, which may be most easily heard when the tip of the finger is put into the ear; it occasions a noise like that of carriages rumbling over a distant pavement. (Wollaston, *Philos. Trans.*, 1809.) The number of these vibrations amount to between twenty or thirty in a second: these muscular sounds are importantly concerned in the diagnosis of certain diseases through the medium of the stethoscope.

MUSCOVA'DO. The name given to unrefined or moist sugar.

MU'SES. (Gr. Μοῦσαι, Lat. *Musæ*.) In the Greek and Roman Mythology, nymphs or inferior divinities, distinguished as the peculiar protectresses of poetry, painting, rhetoric, music, and generally of the *belles lettres* and liberal arts; with which, indeed, they are sometimes identified: — *Quis est omnium, qui modo cum Musis, id est cum humanitate et cum doctrina, habeat aliquod commercium, qui*, &c. (Cicero, *Tusculan.* lib. v. cap. 23.) Helicon and the region round Parnassus was the favourite seat of the Muses, where they were supposed, under the presidency of Apollo, to be perpetually engaged in song and dance, and in elevating the style and conceptions of their favoured votaries. It appears probable that the early Grecian poets, struck with the beauty and sublimity of the scenery in this part of Greece, ascribed the humanizing influence it was so well fitted to exercise over the mind to the agency of the nymphs and other tutelary deities of the place, to whom they gave the name of Muses. Originally there appear to have been only three of these divinities *; and their names — *Mneme*, *Melete*, and *Aœde*, or Memory, Reflection, and Song — sufficiently show the nature of the faculties over which they were supposed to preside. According as the fine and liberal arts were cultivated and expanded, the province of each muse seems to have been more restricted; and additions were made to their number, which ultimately was fixed at nine. Their names and functions are succinctly stated in the following verses of Ausonius: —

> CLIO gesta canens, transactis tempora reddit.
> MELPOMENE tragico proclamat mœsta boatu.
> Comica lascivo gaudet sermone THALIA.
> Dulciloquos calamos EUTERPE flatibus urget.
> TERPSICHORE affectus citharis movet, imperat, auget.
> Plectra gerens ERATO, saltat pede, carmine, vultu.
> Carmina CALLIOPE libris heroica mandat.
> URANIA cœli motus scrutatur, et astra.
> Signat cuncta manu, loquitur POLYHYMNIA gestu.
> Mentis Apollineæ vis has movet undique Musas.
> In medio residens complectitur omnia Phœbus.
>
> EDYLL. 20.

MUSE'TTE. A name sometimes given by the Continental nations to the bagpipe. The itinerant performers on the musette, who were formerly very numerous in many European countries, were called *musars*.

MUSE'UM. (Gr. *μουσειον*; from *μουσα, a muse.*) A collection of curious objects in nature and art; but, in most instances, the former. The name denotes a temple or place sacred to the Muses; and is said to have been first given by Ptolemy Philadelphus to that part of the royal palace at Alexandria in which he placed the famous library. In England, the museum at Oxford is the most ancient institution bearing the name. It was founded in 1679, and enriched, in the first instance, chiefly by the contributions of Elias Ashmole; but want of room and of funds has prevented it from affording an adequate exhibition of the various classes of objects for which it was originally destined, and which modern discoveries have so greatly augmented. The foundation of the British Museum, in London, was laid by Sir Richard Cotton's presenting to it his collection of manuscripts. Since that period the library has been increased by the addition of the Harleian, Lansdowne, Egerton, and several other collections of MSS.; by extensive purchases out of funds afforded by government; by the deposit of copies of newly published works, according to the legal right conferred on this institution; and by the donations of George III. and IV., the latter of whom presented to it his father's library. In sculpture, the British Museum possesses the collection of marbles brought by Lord Elgin from Greece, together with that called the Townley marbles, and a fine assemblage of Egyptian works of art. It contains also the Hamilton vases, and the famous Barberini or Portland vase. In several departments of natural history, especially in mineralogy, it is extremely rich. It was founded by Sir Hans Sloane in 1733, and fills the mansion known by the name of Montague House, together with adjoining buildings more recently erected. The most celebrated museum in Italy is the Vatican, at Rome; next to it, that of Florence; and the Museo Borbonico, at Naples. In France, as well as in Italy, galleries of pictures are considered as within the meaning of the general term "musée;" and the museum of the Louvre is chiefly remarkable for its contents of this description.

MU'SHROOM (Fr. mousseron, a kind of agaric used in sauces), is, properly speaking, the *Agaricus compositis*, or eatable agaric, — a species common in pastures, and well known for its excellence as an ingredient in sauces; but the term is generally used in a more extended sense, and applied indiscriminately to all firm fleshy species of the genus *Agaricus*, whether eatable or not.

MUSIC. (Gr. *μουσικη*.) The art of combining sounds agreeable to the ear. This art becomes a profound science when we investigate the principles on which its combinations are founded, and the causes of the emotions it produces.

Hebrew Music. — Notwithstanding the great labours of the early fathers of the church, and of many other learned men, there are few materials, even in the Scriptures themselves, for a very satisfactory account of the music of the Jewish nation, whose restricted intercourse with other nations prevents our receiving any illustration of it from contemporary writers. All that can be done is to cite a few passages from holy writ relative to the first ages of the world; from which it will be seen that, from a very early period, the art constantly ministered to the religious ceremonies of the Hebrews. Moses (*Gen.* iv. 21.) tells us that Jubal, sixth in descent from Cain, was "the father of all such as handle the harp and organ." The organ here mentioned, according to the commentators, was the syrinx, or a species of Pan's pipes. This must have been but a short period after the deluge. Six hundred years after this period Laban reproaches Jacob thus: "Wherefore didst thou flee away secretly, and steal away from me? and didst not tell me, that I might have sent thee away with mirth and with songs, with tabret and with harp?" So that at this time vocal and instrumental music was not unusual. For two hundred and fifty years after this period nothing occurs relative to music, when we find Moses, after the passage of the Red Sea, singing with the Israelites on the occasion. Miriam, Aaron's sister, "took a timbrel in her hand; and all the women went out after her with timbrels and with dances." There seems ground for conjecturing that Miriam, by birth Egyptian, and educated in Egypt, might have learnt the use of the timbrel and the dance in that country. The instruments mentioned, during the administration of Moses, appear to have been confined to the trumpet and tambourine. After the siege of Jericho, where the rams' horns that were blown were rather military signals than instruments of music, we have no record of music till the appearance of the canticle of Barak and Deborah, which seems to have been sung in dialogue without instruments, excepting the timbrel and the trumpet before mentioned. From several passages music appears to have been united with prophecy. Samuel (b. 1. ch. x. v. 5.) says to Saul, "Thou shalt meet a company of prophets coming down from the high place, with a psaltery, and a tabret, and a pipe, and a harp before them." These prophets were doubtless poets or psalmodists, improvisatori of verses which they sung to the accompaniment of an instrument; and many of the fathers have supposed that the Jews had a college or school of prophets, which was also a school of music, for they almost universally accompanied themselves, or were accompanied by others, with musical instruments. David, who had cultivated music from his infancy, seems to have been destined by his family to the profession of a prophet; and Saint Ambrose says that he was chosen by God, above all the other prophets, to compose the Psalms. The power that the harp of David had upon Saul, when he was tormented with the evil spirit, is an example, among many others, of the influence of music on the maladies of the mind, and especially in cases of melancholy. Under the reign of David music was much esteemed. He appointed a great corps of musicians for the celebration of the religious ceremonies, and his patronage necessarily extended its influence. David, on all occasions, seems to have been interested in the solemnities of his time: we find him continually dancing and

* Cicero says four (*De Nat. Deorum*, iii. cap. 21.); but in this he is at variance with the Greek authorities. (*Pausanias*, lib. ix.)

playing before the Lord, with songs, harps, psalteries, timbrels, cymbals, cornets, and trumpets. As in Egypt, the musicians were confined to one family, that of Levi, which was exclusively consecrated to the service of the Lord and the cultivation of music. When Solomon was made king, four thousand were the number "which praised the Lord with instruments." Dr. Burney calls the reign of Solomon the Augustan age of the Jews; and though Solomon, unlike his father, was not himself a performer, and ranked "men-singers and women-singers, and the delights of the sons of men, such as musical instruments," among the vanities of the world, yet he continued the priests and Levites in his employ. In the reign of Jehoshaphat, the Levites were useful in the field of battle, and were, by their songs, the cause of the victory that was gained; and indeed this was not the only instance in which they were similarly serviceable. Some time before the destruction of the temple and the first Babylonish captivity, music and the sacred rites had met with interruption, both on account of war, and by their intercourse with foreign nations. The captivity was a mortal blow to the endeavours they had made to recover their music; and sixty-six years, the period of its duration, was sufficient to efface all from their remembrance. This oblivion is feelingly deplored in the 137th Psalm, "How shall we sing the Lord's song in a strange land?" Re-established, but soon afterwards captives a second time; again delivered, and then conquered by the Egyptians, Persians, and Romans successively, — the unfortunate Jews had no leisure to cultivate the arts; and it appears probable that their music, which scarcely deserved the name till the reign of David, even at its best epoch, depended for effect more upon the number of the performers than upon any refined knowledge of the art.

Among the modern Jews, instrumental as well as vocal music was excluded from the synagogue from the time of the destruction of Jerusalem. The singing they allow at the present day is a modern innovation; for, according to a passage of their prophets, the Jews consider it contrary to their law, or at least improper, to sing or rejoice until the coming of the Messiah. The German are the only Jews in the present day who have a regular musical establishment in their synagogues. They sing in parts, and have preserved traditional melodies, which are considered very ancient. At Prague an organ is used to accompany the singing.

Egyptian Music. — The opinion of the ancients was pretty general that Pythagoras was indebted to the lessons of the Egyptian priests for nearly all the science he possessed, and especially that of music. Though Diodorus Siculus assures us that the Egyptians were not allowed to cultivate music, and that they considered it useless and even injurious to society, and the cause of effeminacy; yet Plato, who had visited Egypt, observes, in one of his Dialogues, that none but excellent music was allowed where the youth were assembled. Though he admits others of their habits were bad, he excepts the music. Strabo tells us that the youth were instructed at the earliest age in music, that the songs were fixed by law, and that the sort of music used was established by the government exclusive of every other sort. The Greeks even attributed the invention of some of their musical instruments to the Egyptians; such as the triangular lyre, the single flute, the drum, and the systrum. Herodotus says the Dorians were of Egyptian extraction; and as the three most ancient modes of Grecian music were the Dorian, the Phrygian, and the Lydian, it is probable that the Egyptian colony that peopled that province carried thither the music and instruments of their country. Like all other professions in Egypt, that of music was hereditary. A similar custom, as we have above stated, prevailed among the Jews; and Herodotus tells us that the inhabitants of Lacedæmonia, who were Dorians, resembled their ancestors, the Egyptians, in this, that their musicians were all of the same family; and that their priests, like those of Egypt, were taught medicine, and the art of playing upon stringed instruments, when they were initiated into the mysteries of religion. The same author mentions that in the processions of Osiris the Egyptians carried statues of the god, singing his praises, and were preceded by a flute. There is a singular proof of the antiquity of this art to be met with at Rome, on the Guglia Rotta, which Augustus brought to Rome, being one of the largest obelisks that was removed from Egypt, and which was thrown down and broken at the sacking of the city, in 1527, by the constable of Bourbon. It is, among other hieroglyphics, the representation of an instrument, as here given, very like the

colascione (a species of guitar) still in use in Naples. From the pegs it is evident two strings were employed; and the length of the finger board, if the strings were tuned at a great interval from each other, would afford a very considerable scale of notes. This instrument alone proves to what extent music was cultivated in Egypt, and that its inhabitants were acquainted with the method of repeating the scale. Hermes, Toth, or the ancient Mercury Trismegistus, to whom is ascribed the invention of writing, astronomy, religious rites and ceremonies, has the credit also of having invented the lyre with three strings, which, it is pleasantly said, were types of the three seasons of the year, there being a fourth season neither in Egypt nor among the ancient Greeks. The lowest chord, say they, was the type of winter, the middle one of spring, and the highest of summer. The following, according to Apollodorus, was the origin of the invention:—The Nile, after its inundation on one occasion, left on retiring a quantity of dead animals, and among the rest a tortoise. The flesh soon perished and dried up, from the heat of the sun; nothing but the shell and the cartilages were left, and from their contraction they had become sonorous. Mercury, strolling on the banks of the river, struck his foot against this tortoise-shell, and was agreeably surprised by the sound it produced; and this furnished him with the first idea of a lyre. He gave his instrument the general form of the shell, and strung it with the dried tendons of animals, resembling the gut-strings of the present day. The single flute, however, *monaulos*, also invented in Egypt, seems to have greater claims to antiquity than the lyre itself. It was called *photinx*, or curved flute, by the Egyptians; its form being something like that of a bullock's horn.

Apuleius, describing the mysteries of Isis, tells us the form of this instrument, as well as the manner in which it was held; and all the representations of it show that it resembled the bullock's horn. Indeed, there can be no doubt that, in the remotest period, the horns themselves were made use of. But it is certain that the Egyptians had instruments much more susceptible of inflection than those whereof we have been speaking; for on the ceilings and walls of the chambers of the tomb of Osymandyas,

at Thebes, which are described very circumstantially by Diodorus, are, amongother decorations, several representations of musical instruments; one of which, from Denon, we here subjoin, for the purpose of showing the reader that the harp of the present day is in general form not very dissimilar to that then in Egyptian use, and that performance upon it must have required considerable skill. Other representations of harps occur; one has been given by Dr. Burney. There is one at Ptolemais, a city built by Ptolemy Philadelphus, with fifteen strings, or two complete octaves: this, however, is more triangular in shape, and much more similar to the modern harp. The instruments in Abyssinia were found by Mr. Bruce to have a close resemblance to those of Egypt. The arts which flourished in this nation at so early a period would doubtless have continued to do so under their own kings; but after the subjugation of the nation by Cambyses, 525 years before Christ, the arts and sciences under a foreign yoke disappeared, or rather ceased to be indigenous in Egypt. The Ptolemies, indeed, encouraged them; but under their reigns the professors of the arts were chiefly Grecian. The Egyptians had degenerated from the knowledge of their ancestors, whose hieroglyphics they themselves no longer understood. It is probable, however, that music was cultivated under these princes; for at a feast of Bacchus, given by Ptolemy Philadelphus, Athenæus says that the choir was composed of six hundred musicians, and of that number one half were performers on the cithara. According to the same author, under the seventh Ptolemy, Egypt abounded with musicians; and at this period the practice of music was so common in the country, that there was not a peasant or labourer in the vicinity of Alexandria that was unable to play on the lyre and flute. The father of Cleopatra, who was the last of the Ptolemies, from his skill on the flute took the title of Auletes; that is, player upon the flute. Strabo says that notwithstanding the debauched life he led, he found time to apply himself particularly to the practice of this instrument. He thought so highly of his talent in this respect that he established musical competitions in his palace, and himself disputed the prize with the first musicians of the day. Such was the flourishing state of the art in Egypt up to the time of Cleopatra's misfortunes; — an event which ends the history of the empire, and that of the Egyptians. Among the modern Egyptians no remains or traces of the ancient state of the art are now to be found. Still they are passionately fond of music; and there are, according to Savary, to be found among them both male and female musicians who sing and accompany themselves. This author describes them as most successful in their plaintive music; to which, he says, even

the Turks themselves, the enemies of art, will pass whole nights in listening.

Grecian Music. — The fables of mythology are so mixed up with the ancient history of all the arts that it is difficult to separate fact from fable. Hence the most celebrated authors of the history of music, after delivering faithfully what the ancients have recorded on the subject, have left the reader to shift for himself in analyzing the mass. Burney, of whose history in the two previous articles we have largely availed ourselves, we propose to follow in the following short account of Grecian music. The Phœnicians came into Greece with Cadmus, the son of Agenor: amongst them were a class of men well versed in the arts and sciences of their country, who were called Curetes. These established themselves in Phrygia, where they were called Corybantes; in Crete, where they received the name of Dactyli: they spread also into Rhodes, Samothracia, and other places. In these places writing and music were the arts principally taught by them. Cadmus, in Samothracia, took to wife Harmonia (sister of Jasius and Dardanus), who was so skilled in music that the Greeks gave her name to the art. Diodorus, in describing the marriage feast of the parties, makes the gods themselves guests. Mercury came with his lyre, Apollo brought a similar instrument, Minerva assisted with a flute, and the Muses also brought their flutes; Electra, the mother of the bride, celebrated the mysteries of Cybele with dancing, tambourines, and cymbals. How Diodorus was informed of these particulars he does not condescend to tell his readers; but it seems probable that the story was founded on ceremonies which the priests, at certain festivals, performed in honour of Harmonia and Cadmus. Jupiter, they say, was born at the epoch of the arrival of the Phœnicians; and the Curetes, it appears, brought him up. At that time they were not acquainted with any musical instruments, save those of percussion: they could not, therefore, have taught the Greeks more than the use of these, and they could convey no musical notions except those of rhythm. The inferior divinities — Minerva, Mercury, Apollo, and the Muses — afterwards became the protectors of the art, and invented wind and stringed instruments.

These two circumstances are, as the reader will perceive, irreconcileable; and Diodorus committed an anachronism, which may be accounted for if his description was taken from some religious spectacle. The flute with holes, by stopping which many notes were produced, was certainly a more ingenious instrument than the pipes of Pan. This was the invention of Minerva, who performed upon it until she was derided by Juno and Venus for the grimace and wry faces consequent on playing it, when she renounced it in favour of the lyre. The employments assigned to Mercury by the Greeks may be learnt from the pleasantry of Lucian. The same personage as the Hermes of the Egyptians, he had the credit of having invented music, and in those days its principal instrument, the lyre. In Greece the lyre he invented had seven strings, whereas that which he gave the Egyptians had three only. Apollo was another of the Grecian deities whose origin was in Egypt. He was a performer on the lyre; and there is no necessity to repeat in this place his contest with Pan, and the decision of Midas, under whose form the silly king of Phrygia was represented by some neglected poet. Marsyas was another of Apollo's unfortunate victims; upon him he wreaked his vengeance with such cruelty that he himself was afterwards ashamed of his conduct, and actually threw aside his lyre for a considerable period, which, it is said, retarded the progress and perfection of that instrument. Fortunio Liceti, a modern writer, thus explains the story of the flaying Marsyas alive by Apollo. Before the invention of the lyre, the flute was considered the most important instrument, and its practice enriched the performers on it. As soon as the lyre was heard, it was so captivating that nobody listened to flute-players, and they fell into discredit and were ruined. Now the money of those days, being made from leather hides, gave rise to the story that Apollo had stripped Marsyas of his hide. The priestess of Apollo at Delphi delivered, says Plutarch, her oracles to the sound of the flute. Afterwards, when her oracle was in the greatest renown, there were attendant choirs and instruments, and dancing and singing. At first the Muses were nothing more than a band of singers and musicians in the service of Osiris, or the Egyptian Bacchus, under the superintendence of his son Osiris. The Greeks made them the daughters of Mnemosyne by Jupiter. Those who make them the daughters of Pierus, king of Thrace, do not alter the first account; for the female musicians of Osiris, before they were taken into his service, had been celebrated in Thrace under the name of Muses, and the daughters of that Pierus who initiated them became celebrated under the same name. Bacchus has been so celebrated in the musical world that we cannot leave him out. Diodorus makes him the inventor of theatrical representations and schools of music, in which those who excelled were exempt from military service. Hence the author says that musical societies have since enjoyed many privileges. Certain it is that the Dithyrambi, who originated dramatic representations, were as ancient as the worship of Bacchus. In Athens and in Rome all persons who appeared on the stage, singing, dancing, or reciting verses for the amusement of the people, were called servants of Bacchus; and at all the processions, triumphs, and ceremonies instituted by the ancients in honour of the god, music entered largely into the programme. This is constantly seen in the bas-reliefs that have come down to us; for wherever there are fauns, satyrs, and bacchanals, we always find a certain set of musicians of some sort in attendance.

Pan seems to enjoy the first rank in the second class of divinities who patronised music. The Egyptians, however, ranked him higher than did the Greeks. Pan, say some, was the inventor of the flute called the syrinx. The fable is pretty which gave rise to the invention. Syrinx, a nymph, being pursued by Pan, flies to the banks of a river, whose nymphs she implores to save her. Pan thinks to catch her, but embraces only the reeds. Under this new form, Syrinx, shaken by the winds, emits certain melodious tones. The god, pleased with the sound, makes an instrument from the reeds, to which he gives the name of Syrinx. Pan is the companion and counsellor of Bacchus. Shepherd, musician, dancer, hunter, and warrior, he directs the movements of the bacchanals; but the perfection with which he plays the flute is such that Bacchus is never happy without him. The satyrs follow in Pan's train. Silenus was the inventor of several instruments. Like Marsyas, he was bold enough to challenge Apollo; with better fortune, however, as regards the result.

Such was the state of music in Greece under the gods and demi-gods; that is to say, in those primitive times when every one who had signalized himself by a useful invention was deified after his death, and considered the protector of the art he had invented. The heroic age followed this; and, divesting the subject of fable as much as possible, we shall now proceed to the music of that period. Amphion, Chiron, Orpheus, Linus, were at once the first poets and the first civilizers of Greece. Amphion is the first Theban musician mentioned in the history of the art. Homer, however, is silent on his wonderful skill in music, and of his having erected the walls of Thebes by the aid of the lyre. Pausanias thinks his musical reputation was acquired by his alliance with Niobe, and Pliny is of the same opinion. Both of them allege that Amphion learnt the art in Lydia, and that, having brought it into Greece, he was thence accounted the inventor of the Lydian mode. Chiron, whom Plutarch calls the wise centaur, accounted the son of Saturn and Philyra, was born among the centaurs in Thessaly; that is, among the people of Greece who first trained and rode the horse. With the reputation of inventor of medicine, botany, and surgery, he lived at the foot of Mount Pelion, in a cavern, which his science made the principal and most frequented school of Greece. Plutarch makes him the instructor of Hercules in music, medicine, and law; though Diodorous says that Linus was his master. And here let it be observed that ancient authors always considered music among the indispensable accomplishments of their heroes. "Nec fides didicit nec natare" was anciently a reproach to any one above the commonest class. Achilles was the most renowned pupil of Chiron, who bestowed much of his time to instruct him in this art, as the means of not only softening the impetuosity of his character, but of exciting him to heroic actions. One of the most beautiful paintings of Herculaneum represents Chiron teaching the young Achilles to play upon the lyre. After Chiron, Linus and Orpheus appear to have been the first poets and musicians of Greece; but it is difficult to decide which was the pupil of the other. Diodorus says that Linus has the priority, and that he added the chord lichanos to the lyre of Mercury, and invented rhythm and melody. The majority of the ancients make him the instructor of Hercules, whom, say they, he found so stupid and obstinate, that having on one occasion given him a blow, the young hero seized his preceptor's instrument and beat his brains out with it. Orpheus, however, whether before or after Linus, acquired the greatest name in Greece. His reputation was fully established at the time of the Argonautic expedition, in which he was one of the adventurers. Apollonius Rhodius observes, that he not only excited his comrades by the sound of his lyre, but that he also silenced the syrens by the superiority of his singing. The fables universally say that Orpheus travelled in Egypt, where he was instructed in the mysteries of religion, theology, and poetry, and that he was the first who transplanted them to the Grecian shores. According to the custom of the time, he united with the knowledge of music that of the sublime sciences. Preferring the lyre to all other instruments, of which before him the flute seems to have been the principal, those who followed were content to be his imitators. We pass over the story of his losing Eurydice, his wife, the effect his lyre had upon Cerberus and the god of the infernal regions, as known to every reader.

The instrument that produced these effects was but a seven-stringed lyre; two strings having been added by himself, by which addition the second tetrachord was completed.

Obloquitur numero septem discrimina vocum. — VIRG.

From the little power which such an instrument possessed, compared with those of modern times, we may infer that it must have been the novelty of the art or the beauty of the poetry which produced such extraordinary impressions, or perhaps both acted upon a very susceptible race of people. The mastery which Orpheus possessed over the Thracians made the women of that country jealous of him; and by them, history relates, he was massacred. In the time of Plutarch, the females of Thrace continued to be reproached with this barbarity. The fable says that his lyre, at the time of his murder, fell into the river Hebrus, down which it floated to Lesbos, where it was deposited in the temple of Apollo. Neanthus, who afterwards purchased it of the priests of the temple, thought, like the nobleman who bought Punchinello, that the possession of it would inspire him: no sooner had he begun to use it than the dogs of his neighbourhood tore him to pieces. After the Argonautic expedition, the most important event in Grecian history is that of the siege of Troy. Homer, who sang three centuries after this period, is the only historian from whom we can extract knowledge respecting the art. He has preserved the names of several musicians; and these are the only ones known from the time of Orpheus up to the time of celebrating the Olympic games.

The instruments mentioned by Homer, in the *Iliad* and *Odyssey*, are the lyre, the flute, the syrinx, or Pan's pipes. The lyre is by him called φορμιγξ, κιθαρα, and χελυς; Aristophanes being the first Greek poet who calls it λυρα. Though Homer speaks of the trumpet, it is thought that this instrument, though common in his time, was unknown to the Greeks at the siege of Troy. With Homer music and poetry are inseparable: *αοιδος, a singer*, is the word used by him to express a poet. By him Achilles and Paris are both exhibited as playing the lyre; but the former does it to console himself for the insult that had been offered to him; whilst the latter exercises his skill to forget the disgrace of having sought safety in flight. Achilles sings the deeds of heroes. The song of Paris was more "to the lascivious pleasing of the lute," in recounting tales of love. The earliest poet who united music with his art was Tiresias: he was also gifted with prophecy, and was a priest. Thamyris receives from Homer the appellation *κιθαριστης, one who sang to the lyre*. Plutarch, in his Dialogue on Music, says that he was born in Thrace, the country of Orpheus; that his voice, though loud, possessed the quality of softness; but that he was punished with blindness for daring to contend with the Muses in poetry and singing; and that to this punishment was also added the loss of voice, and the talent of touching the lyre. This circumstance is mentioned in the catalogue of the ships. (Lib. ii. v. 594.) According to Diodorus, Thamyris was of the school of Linus, and Suidas places him eighth of the epic poets who preceded Homer. Clemens of Alexandria says he was the inventor of the Dorian mode; but he is probably wrong, inasmuch as this had before his time been imported into Greece by the Egyptians, who invaded that part of Greece which bore the name of Doria. In the eighth book of the *Odyssey*, Homer gives an eminent place to Demodocus, whom he describes in his character of poet and singer as the glory of the human race. Some have thought that under this name the poet was painting his own portrait. He places him on a throne, a herald announces him, and he has a private table, and in every circumstance speaks of the honours that were paid to him. Like Tiresias and Thamyris he paints him blind, which it will be recollected was his own case. The blindness of these great poets did not escape Milton, who likens himself to them in this respect, and the coincidence is certainly very singular. The last musician celebrated by Homer is Phemius, who, according to Eustathius, had been his master. He is immortalized in the *Odyssey*. The poets and musicians of Greece appear to have much resembled the Celtic bards. They wandered about, singing their works in great cities, and usually found admission to the palaces of princes, where they were treated as though endued with inspiration. Hyagnis and Olympus were also celebrated, before the time of Homer, for their musical talents: the first, according to the Arundelian marbles, flourished 1506 years B.C. He was the inventor of the Phrygian flute, and the airs or *nomes* that were sung to the mother of the gods, to Pan, Bacchus, and other divinities of the country. The second is honourably mentioned by the Greek writers. Two musicians of antiquity bore the name of Olympus. The most ancient was the most celebrated. He was a native of Mysia, and the disciple of Marsyas. Burney, in speaking of him, remarks that religion only can impart permanence to any system of music; and he conjectures that the airs that were sung in the temples in the time of Plutarch were then of the same relative antiquity as to us is the plain chant of the beautiful hymns of the Catholic church. Plato, Porphyry, Athenæus, and the scholiast of Pindar, speak highly of the talents of Thaletas of Crete, the next poet and musician after Hesiod and Homer. There were two of this name, of the same country too. If we are to credit Plutarch, Archilochus contributed more than any other to the advancement of poetry and music. Herodotus makes him the cotemporary of Candaules, and of Gyges, king of Lydia, 724 years before Christ; but modern chronologists place him much later. He was a native of Paros.

Without entering into particulars, it is sufficient to mention that at this period melody was strictly confined by the measure of the verse. A different set of feet in a verse necessarily required new airs in the music. Hexameter was the most ancient species of measure, and so continued till the introduction of lyric poetry. If Archilochus was the inventor of music different to that which suited the hexameter verse, he was indeed the inventor of lyric poetry, which after his time became a species of versification totally distinct from that of the heroic. Archilochus is generally allowed to have been one of the first conquerors at the Pythian games. Tyrtæus, who was a soldier as well as musician, was particularly celebrated for his military songs or airs. The scholiast of Horace makes the Lacedæmonians indebted to him for a victory gained by them, in which he led them on to the sound of the military flute, for which they rewarded him with the rights of citizenship. The authors who have written on the progressive state of the Grecian music unanimously celebrate the talents of Terpander; but neither the exact time of his appearance, nor the place of his birth, can be ascertained. According to the Arundelian marbles, the former was 671 years before Christ. Many have given him the credit of having added the three strings to the lyre: it, however, appears clear that he was the first who used the seven-stringed lyre among the Lacedæmonians, by which he gave great offence to the people. The Spartans disliked innovation, and Plutarch relates that the Ephori fined him for his invention. The Arundelian marbles state that he obtained the first prize in music at the games instituted at Sparta to avert the anger of Apollo for the murder of one of his priests by the Dorians. Plutarch says that no other proof of his skill could be wanting, seeing that his name appears four times on the register of the Pythian games, where he carried off successively four of the prizes. At the Grecian games music formed a principal part of the ceremony: the combats were to the sound of music. In the dramatic representations, the declamation was accompanied by an orchestra, and there were moreover particular prizes allotted to the professors of the art. The Olympic games were established in honour of Jupiter Olympius, from which, or from being celebrated near the temple of Olympia, they took their name. They were not at first celebrated at stated intervals, but, after the year 776 B.C., on the second month after the expiration of every fourth year. At first music had but little share in them, but at a later period prizes were given to successful competitors in this art. It is well authenticated that, at a comparatively late period, Nero appeared at them, and of course carried off the prize. The Pythian games, founded for preserving the remembrance of Apollo's victory over the serpent Python, were at first confined to poetical and lyrical contests; but in these music was afterwards admitted to her share of the prizes; and, in the year 559 before Christ, a crown was decreed to the best performer on the lyre, or, rather, on an instrument with strings. The prize was nothing more than a laurel crown, in memory of the love of Apollo for Daphne; though afterwards the apple, a fruit consecrated to Apollo, was added. At these games a peculiar musical composition was performed of considerable length, in allusion to the contest of the god with the serpent: it was composed by Sacadas, and sung for the first time by him at Delphi. The other musicians and poets who distinguished themselves at these games were Alcman of Sardis; Alcæus of Mitylene, the cotemporary of Sappho (to the latter of whom Aristoxenus and Plutarch attribute the invention of the Mixolydian mode, of which Plato, the advocate of simplicity in music, much complains); Mimnermus, famous for his performances on the flute, in the 6th century before the Christian era; Hesichorus (a sobriquet), whose right name was Tisias; Simonides, born at Ceos, 538 B.C., the master of Pindar; Pindar himself, born at Thebes, in Bœotia, about 520 years before our era; Myrtis, and Astinous. The Pythian games were held at Miletus, Magnesia, and other places, as well as at Delphi, and music and poetry were the chief subjects of contests in them. The Nemæan games, which took their name from Nemæa, a village in Arcadia, were of such high antiquity that their true origin was unknown even to the ancients. The contests were somewhat similar to those at the Olympic games, and it is known that those in music formed a portion. It was at these games that the musician Pylādes, of Megalopolis, sang, accompanied by the lyre, an air composed by Timotheus, in which the

words were so suited to the circumstances of the battle of Mantinea, that the audience immediately turned their eyes to Philopœmen, who was present, and interrupted the singer by shouts and acclamations of applause. Timotheus, born at Miletus, 446 B. C., was one of the most celebrated poets and musicians of antiquity. Pausanias tells us that to the seven strings of the lyre he added four more; though Suidas says that he added but two, the tenth and the eleventh: the consequence whereof was that for the innovation he was banished from Sparta, and ordered to cut off the additional strings, that he might not corrupt the ears of the youth with too great a variety of notes. We have above stated that the Spartans behaved in an equally barbarous manner to Terpander. This Timotheus, who died two years before the birth of Alexander, must not be confounded with the celebrated flute-player who was so great a favourite with that prince, and whose tones animated him to arms. The Isthmian did not differ from the games already described: they received their name from being celebrated on the Isthmus of Corinth. Other games existed in different cities, as, for instance, the Panathenaic at Athens. Music was cultivated at all, and held in much esteem.

At Athens, in the time of Pericles, music was considered so necessary a part of education, that not to understand it nor play any instrument was considered a disgrace. Pericles was especially zealous in his patronage of music. Besides regulating the form and increasing the number of musical competitions at the Panathenaic festivals, he built an edifice called the Odeum, for the express purpose of rehearsals previous to performance in the theatre. It was during his era that Antigonides and Dorion, the two most eminent flute-players, flourished. So great appears to have been the passion for flute-playing, that as much as three talents (upwards of 600*l.*) were given for a single flute; fortunes were realized in manufacturing them; and the performers lived in a splendid and magnificent style. Even the women were performers on the flute. Of these the most renowned was Lamia, to whom, for the benefits she had prevailed on Demetrius to confer upon the city, the Athenians rendered divine honours, and dedicated a temple to her, under the name of Venus Lamia. It seems that execution on this instrument was carried to a great extent; for Aristotle cries out against the difficult passages that used to be practised, and even against music generally. The people, however, who, as a mass, are never disposed to give up the pleasures of sense for those of the mind, continued to encourage these novelties and their authors; and, from being the handmaid, music became the mistress of poetry. The justice of the complaints of Plato and Aristotle on this point is confirmed by Aristoxenus himself, well skilled in the art; and Plutarch frequently laments that the theatre had ruined music: though what the latter says must be taken with some allowance, seeing that he was a priest of Apollo, and anxious, doubtless, to confine music to the service of religion. After the complete subjugation of the Greeks, like the rest of the arts, music fell to decay. They continued, indeed, to cultivate music under the Roman emperors, and under their own: even afterwards, under the Turks, it was one of their amusements; but so barbarous is it in the present day, that it is difficult to conceive that the same nation ever possessed a music which drew down the admiring plaudits of thousands. To form any idea of the ancient Greek music is now past all hope: materials upon which we could judge have long since passed away; but we will add, in conclusion to this section, the opinion of M. Ginguené on the subject. "We see in the poetical works of the Greeks the variety and liveliness of their passions, and these same passions could not be expressed in music without an equal variety of air and modulation. I do not mean by that to say that Greek music was entirely similar to our own: to decide that point it would be necessary to hear and compare the one with the other. I maintain only that Greek music was full of harmony; that it admitted that variety of modulation which alone can give pleasure to cultivated minds; and that to suppose that the Greeks were pleased with a music that comprehended but four notes is one of the greatest follies that can be imagined."

Roman Music.—It is scarcely possible for any nation to exist without some sort of music; and it appears that, at a very remote period, such was not the case with the Romans. At its commencement rude and barbarous, their intercourse with the Etruscans, who were much farther advanced in the arts than themselves, would soon have had effect upon it. Strabo and Livy affirm that public music, as used at sacrifices, was especially learnt by this nation of the Etruscans. Servius Tullius, 600 years before Christ, in his division of the people into classes or centuries, directed that two entire centuries should consist of trumpeters, horn-players, and those who sounded the charge, which proves at least the number of military musicians. One hundred and fifty years afterwards, the marshal at funerals was, by the laws of the twelve tables, directed to provide six flute-players. Among the Romans, as was also the case with the Greek music (see above), music and the drama were inseparable. In the end these exhibitions became offensive; but the further notice of these is unnecessary in this place. Music, however, was for a long period confined to sacred uses; and it was only after the defeat of Antiochus the Great that the Asiatic custom was introduced of having female musicians,—*psaltriæ*,—to play at festivals and private banquets. The Etruscan music, which we have already slightly mentioned, was cultivated with success; for all the instruments of the Greeks, which are known to us from their bass-reliefs, are to be found in paintings on Etruscan vases: so that it may be safely assumed that the Romans were accustomed to the best music that the age afforded. Under Augustus, who was not a great patron of the art, music was not much esteemed: it is possible he might not have had much taste for it; and yet, when he was getting into years, he engaged a musician to regulate the intonation of his voice. Tiberius banished musicians from the city, which under him became as sad as in the days of Augustus it had been lively. Caligula, however, recalled them. Claudius, though he patronized gladiatorial fights in preference to music, still encouraged the art; but under Nero it shone in all its ancient splendour. Such was this emperor's delight in it, that he passed a great portion of his time in taking lessons of Torpus, the most skilful harpist and lyrist of his day. We have before stated his ardour in the pursuit of the art to have been so great that he contended at the Grecian games. Nero's successors were patrons of the public games, and of dramatic and musical exhibitions throughout the empire. Adrian had always been attached to the arts of Greece. He instituted new games, which his successor Antonine continued. Commodus, whose disposition was similar to Nero's in cruelty, resembled him also in an intense passion for the stage, on which he delighted to appear as a singer and dancer. The fall of the empire necessarily induced the fall of the arts, and music, of course, among the rest: in short, it disappeared with them—with them to spring into new life and surpass all its former glory, after centuries had passed away, and all art seemed to have been lost for ever.

Italian Music.—Italy has been to the rest of Europe in modern times what ancient Greece was to Rome. Though we cannot so well trace the art of music in its early restoration as we can the arts of design, we know that to the religion and church which brought them forward we are indebted for the foundation of all that is good in the musical art. The plain chant of the Catholic church, the foundation to which we allude, is said to owe its origin to Ambrosius, archbishop of Milan, in the fourth century. He, it is generally understood, brought it into form and based it upon rules. Two centuries afterwards Pope Gregory carried it to such perfection that, up to the present hour, it has needed no improvement, indeed seems incapable of improvement, and remains one of the noblest monuments that the art has produced. The music of Italy, aided by a language which Metastasio called *musica stessa*, notwithstanding the revolutions it at first underwent, at length became the guide for the rest of Europe. Even out of the church, as early as the 13th century, music was cultivated; for Prince Conrad, in 1268, went out against Charles I. of Sicily with a female choir singing, accompanied by cymbals, drums, flutes, violins, and other instruments; and it is known that all the courts of Italy were filled with musicians, for the amusement of their sovereigns. At Florence is still in existence a manuscript collection of sacred songs, entitled *Laudi Spirituali*, in honour of God, the Virgin, saints and martyrs, which as early as 1310 used to be sung by a society called the *Laudisti*. A society of this sort existed when Dr. Burney was at Florence in 1770; and he states that he often heard them singing about the streets in three parts, accompanied by a portable organ. When Petrarch was crowned with laurel at Rome, in 1341, music was introduced to grace the ceremony; and from the account of that ceremony, printed at Padua in 1549, it appears that it consisted of instrumental as well as vocal music. To return back a little, it appears that, in 1022, Guido, a Benedictine monk of Arezzo, was the first who imagined the scheme of designating by points, distributed upon lines and spaces, the different sounds of the octave. The French have claimed for Hubald and Odo the credit of this invention, a century before the time of Guido, but we do not think the claim established.

Guido gave to the notes the names ut, re, mi, fa, sol, la, taking them from the first syllables of the hymn of St. John the Baptist, in which they are certainly found:—

> *Ut* queant laxis *re*sonare fibris,
> *Mi*ra gestorum *fa*muli tuorum,
> *Sol*ve polluti *la*bii reatum.

The syllable *si* was afterwards added by a musician called Le Maire. From a manuscript in the Vatican dedicated to Charles, king of Sicily, above mentioned, it appears that Marchetto of Padua had improved the art; for the MS. proves that he was acquainted with dissonances and chro-

matic counterpoint. That the science was making vast strides from the old plain chant is clear from the bull of Pope John XXII., in the early part of the 14th century, wherein complaint is made of what he was pleased to call the abuse of descant, whereby the principles of the antiphonal and gradual had fallen into such contempt that the singers could no longer recognize the foundations upon which melodies were established, and that it exceeded the bounds which the ecclesiastical tones prescribed. Without particularizing the steps by which it continued to advance, the *Ars contrapuncti* of John de Muris, in 1330, laid down laws of harmony, some of which are observed in composition at the present hour. He says that, in the scale of the octave, there are six species of consonances, — three perfect and three imperfect. Of the first sort are the unison, the octave, and the fifth ; of the second sort, the two thirds, major and minor, and the sixth major. It is curious that he did not place the minor sixth among the number of consonances, since it is but an inversion of the major third, which he admits to be a consonance. Prosdoscimus, in 1412, speaks of the fourth, of which no mention is made by De Muris, and treats it as a dissonance ; though, he says, it is less so than the second and the seventh, and that it may be placed in a middle class, between consonances and dissonances. Advanced, however, as the science became at this period, it was not until the middle of the 15th century that the laws of harmony were fixed on that foundation that still bears the superstructure of the refined combinations of even modern music. The first treatise on music that was printed in Italy was towards the end of the 15th century, by John Tinctor ; but that published a few years afterwards, by Franchino Gafforio (printed in 1496 at Milan), excelled its precursor. The claim of the Italians to the invention of counterpoint has been disputed in favour of the Flemings, and also of the English. There is no doubt that the former contributed much to its advancement and perfection ; but the works that are extant, if we are to judge from them, satisfy us that the claim cannot be maintained. In the compositions of this period there is a want of melody which all the display of science and curious combinations they contain could not atone for ; but in the 16th century melody and counterpoint were united by the splendid genius of Palestrina, and some of his cotemporaries and disciples ; and the art was enriched by the treatises of Peter Aaron, Zarlino, Artusi of Bologna, the Venetian Zacconi, and many others, which spread throughout Europe, and left scarcely more to be desired on the first principles of music as a science. Palestrina, the principal cause of this revolution, began his career by a diligent study of the masters who had preceded him, making himself familiar with their difficulties and with their styles. Applying himself to the simplification and purification of harmony, and to the discovery of more flowing and natural melodies, he nevertheless paid a degree of homage to the preceding school, whose pedantry and obscurity he knew how to correct.

The Gothic style of composing masses and motetts on a canto fermo, which he practised in his early compositions, he entirely abandoned after 1570. His style, upon which he was continually refining, became at last the model of the age ; and after his time, for a considerable period, the best ecclesiastical compositions were honoured by being called *alla Palestrina*. Nanino, his fellow student and intimate friend, Cifra, his disciple, Luca Marenzio, and many other masters of the Roman school, gloried to tread in his steps ; whilst Zarlino at Venice, Costanzo Porta at Padua, Orazio Vecchi and Monteverde at Mantua, Bottrigari and Orturi at Bologna, endeavoured, and with considerable success, to build their counterpoint with the clearness, purity, and elegance of the great master of modern music. Among these, Monteverde is particularly to be noticed, for his passing beyond the master whom he followed. He was the first who used double discords, such as the ninth and fourth, the seventh and ninth, and the seventh and second ; as also the unprepared false fifth and seventh. This at the time created great disputes in the republic of music. Monteverde, in prefaces and letters, defended his practice ; but his best defence was to be found in the progress he made. The licences he took, far from being offensive to the ear, were soon adopted by others who had abused them. The passion for fugues, canons, and other difficult compositions of that nature, requiring the highest degree of science, continued in the 17th century, which produced many learned musicians. One of the most extraordinary of these was Francesco Soriano, who published 110 canons upon the hymn *Ave Maria Stella*, for four, five, six, seven, and eight voices ; but Pietro Valentini went far beyond him, and has left, it is to be apprehended, all future canonists in a hopeless condition. He wrote one to the words *Illos tuos misericordes oculos*, &c. resolved in more than two hundred different ways, for two, three, four, and five voices ; another for ninety-six voices ; a third for twenty voices only, but with four different subjects going at the same time. Other masters employed themselves in a similar manner. Of the Roman school, also, Luca Marenzio merits special mention here : though great in church music, he is best known and admired in the exquisite madrigals he composed, which still continue to be performed in this country. Marenzio died at Rome, in 1599. At the head of the Venetian school, the Italians themselves place Adrian Willaert, a Fleming. To him Zarlino attributes the invention of composition for more than one choir. He was maestro di capella of the church of St. Mark at Venice. The works he left are voluminous : his disciples were Cipriano Rore, Zarlino, and Costanzo Porta. The Neapolitan school was one of the most celebrated in Italy, and was established in the 15th century, under the reign of Ferdinand of Arragon, a great patron of all the arts. It was at Naples that Gafforio and Tinctor, whom we have before alluded to, Guarnerio, and many others, distinguished themselves. Church and madrigal music there flourished. In the latter branch, Carlo Gesualdo, Prince of Venosa, showed in an eminent degree the powers of that style of writing. The Lombard school registers the names of Costanzo Porta, its head ; Gastoldi, Guiseppe Biffi, and Paola Cima, of Milan ; Pietro Ponzio of Parma ; Orazio Vecchi of Modena ; and Claudio Monteverde, before alluded to. The most celebrated disciples of Porta were Balbi and Piccioli. Orazio Vecchi was among the first composers of dramatic music, and for a considerable time maestro di capella at Mantua. The Bolognese school comprises few writers in the 16th century, though in that following its professors equalled those of the first rank throughout Europe. Andrea Rota may be considered the head of it. Florence in music seems to take no distinguished place : we know of Alessandro Striggio and Francesco Cortuccia only who enjoyed much reputation.

Dramatic music appeared in Italy in the 15th century, a musical tragedy having been acted at Rome in 1480 ; but the real epoch of the music of the drama can scarcely be dated before 1597, and its first appearance was at Florence. Ottavio Rinuccini is recorded as the poet, and Peri as the musician, both Florentines, and the name of the piece *Daphne*. This priority is, however, disputed in favour of Vincenzo Galileo, the father of the celebrated astronomer, who, desirous of recovering the musical declamation of the Greeks, imagined a recitative applied to the episode of Ugolino in Dante. Up to the middle of the seventeenth century the drama was principally recitative, when, in 1649, Cavalli began to introduce more airs than had hitherto been used, which practice was further extended in the *Doria* of Cesti, composed in 1663 ; after which, for some time, it degenerated so much into *spectacle*, that, in the works represented about the end of the 17th century, neither poet, composer, nor singers are recorded, but the machinist and decorator only. Among the composers were, however, men of great knowledge and genius, such as Gasparini, Perti, Colonna, Lotti, and Alexander Scarlatti, who is said to have been the inventor of the obligato recitative. Great improvements were introduced in the beginning of the 18th century by the pupils of Scarlatti ; viz. Leo, Vinci, Sarro, Hasse, Porpora, Feo, Abos, and particularly Pergolese. About the middle of the century appeared Jomelli, Piccini, Sacchini, Guglielmi, Traetta, Anfossi, and others, whose names are not less celebrated than their predecessors, and the century closes with Paisiello and Cimarosa. It remained, however, for a Bohemian, Gluck, to accomplish the revolution which has brought the opera to its present state in Europe. The great improvement in instrumental music towards the end of the last century induced operatic accompaniments with all the richness of the symphony, which, under Haydn, Mozart, Cherubini, Spohr, Weber, and many others, seems to have reached almost the height of power and effect that music can give.

Europe is as much indebted to Italy for the introduction of instrumental as for that of vocal music : the Italians have been the instructors in both. Violin music was cultivated by Corelli and Tartini, and their pupils, before other nations had thought of it ; and the same may be said of the harpsichord, from Frescobaldi to Clementi. So, in concerted pieces, Boccherini introduced the quintett ; and indeed, short of the symphony, which we owe to the Germans, their early superiority cannot be disputed. In our time a sensible decay is visible in Italian music ; the art seems to have left its ancient seat to abide in Germany, where it has been cultivated with an ardour and success perfectly astonishing.

German Music. — Like all other nations, the Germans owe their music to the Italians. They received the Gregorian chant from Italy ; and, though they may not have equalled their masters in vocal melody, they have greatly surpassed them in instrumental music. It is certain that, at the beginning of the 17th century, the music of Germany was greatly inferior to that of Italy ; and it was not till the end of this century that the Germans began to evince high and successful talent for the art. We are not acquainted with any of the earlier music of the German church, — similar in character, we mean, to that produced by the school of Palestrina in Italy ; but in later times the

writings for that church, by Graun, Haydn, and Mozart, have never been surpassed nor equalled; and though these very much partake of the symphony and drama, there is a pathos and sublimity about them calculated in the highest degree to inspire devotion. In the madrigal style we believe they exhibit no specimens, which is the more remarkable, from the circumstance of the German school having been considered by some to have been of as early an origin as the Flemish. Their oratorios possess the greatest beauties: we need only name the *Ascension* and the *Israelites*, by Bach; the *Death of Jesus*, by Graun; and the *Messiah*, by Handel. Though not so old as that of Italy, the German theatre is nevertheless of early origin; but until Keyser appeared to compose for the theatre at Hamburg, about the end of the 17th century, it was without celebrity. During the whole of the last century, the German composers bred in the Neapolitan school carried their style into Germany, where it became predominant, and the model of the country. John Adolphus Hasse had the principal share in the transference of this style, which, improved by Graun, Neumann, Gluck, and carried still further by Haydn and Mozart, has travelled back to Italy, to shine second-hand in Rossini and others, but without the lustre of the Germans. Gluck, of whom we have spoken above, though by birth a German, belongs properly to France; for, strange to say, he was not properly appreciated by his own countrymen, though in later years they found out their error, and acknowledge it still by the rapture with which his works are now received. Germany derives its greatest reputation from the success with which it has cultivated instrumental music. In harpsichord and piano-forte music, it may be safely said they have surpassed all other nations; for it would be difficult to place names in that respect of equal reputation by those of J. S. Bach and his children, of Haydn, Kozebech, Mozart, Dussek, Cramer, and a host of others. The music of wind instruments seems to belong now almost exclusively to Germany: their organists are excellent, and their orchestras well regulated. In musical literature they are superior to every other nation: witness the works of Fux, Mattheson, Marpurg, Kirberger, E. Bach, Albrechtsberger, Forkel, Koch, and a host of others, most of them of the 18th century. In the present day, it is by no means surprising that the success of the Germans should be so extraordinary, seeing that there is no school *for the education of youth in the country* at which music is not taught and cultivated, even down to those where children receive gratuitous instruction.

Flemish Music.—The Flemish have been frequently confounded with French musicians; so that it is rather difficult to separate, at times, the one from the other. Louis Guicciardini (*Descrizione di tutti i paesi bassi*, published 1556) gives a list of all the musicians born in the Low Countries, who were then dispersed in different parts of Europe, which robs the French catalogue of some of its most distinguished names. From the 15th century Flanders, from its commerce, and wealth, and superfluous riches, was enabled to patronise the fine arts; and most especially was that the case in the times of Charles V. and Francis I. Upon these monarchs, who lived less in their own capitals than elsewhere, the arts seem every where to have been attendant; and when we recollect their frequent sojourn at Brussels, Antwerp, and other cities of Flanders, we are not surprised at the number of excellent musicians that Flanders produced. The John Tinctor of whom we have heretofore spoken flourished about 1474: he was a native of Flanders, and maestro di capella to Ferdinand of Arragon, King of Sicily and Naples. He is the earliest theoretician whose name has reached us. Soon after, or contemporary with him, was John Okenheim, the first composer of music in parts. From the fragments which have been preserved by Glareanus, he appears to have been a learned writer, whose works seem more calculated to please the eye than the ear; and from the authors of the following century who notice him, we learn that he was the writer of a motett in 36 parts. Josquin, or, as the Italians call him, Josquino del Prato, was Okenheim's most celebrated scholar. The laws and difficulties of canon, fugue, augmentation, diminution, inversion, and other practices of church music, were by him observed and overcome in the most felicitous manner; and he has by some been dignified with the title of father of modern harmony, inasmuch as his era is nearly a century before that of Palestrina, Orlando di Lasso, &c. It is proper to state that Guicciardini claims Josquin as an Italian; and, at least, there can be no doubt he was educated in Italy, inasmuch as he was a singer in the chapel of Sextus IV. His compositions were extremely numerous, and as often executed in the beginning of the 16th century as those of Handel were in England fifty or sixty years ago. His death took place at Brussels; and his monument is still to be seen in the church of St. Gudula. Hobrect, or Obrect, was a good composer of this period, and adds to his talent the honour of having been selected by Erasmus to instruct him in the principles of his art. We must pass shortly over the names of Pierre de la Rue, or Petrus Platensis, as he was sometimes called, Jean Mouton, Verdelot, Nicolas Gambert, maestro di capella of Charles V., Jacques de Wert, Pevernage, Lupi, Waelrent or Wraelrent, Verdonk, Arkadelt, and others, many of whom are still known to the musical antiquary by their madrigal compositions, though they were called only songs for parts in Flanders. Between 1544 and 1555 there were more than twenty collections of these *chansons* or madrigals published at Antwerp and Louvain, by Tylman, Susaro, and Pierre Phalaise, who were themselves good composers; as were, in the same century, the publishers Rhau at Wittenberg, Gardano and Scotto at Venice, Ballard in France, and Tallis and Bird in England. After Clemens (non papa), an elegant and exquisite, though not voluminous writer, and Cypriano Rore, a pupil of Adrian Willaert, must be recorded the name of Orlando di Lasso, one of the most diligent and celebrated writers of the 16th century. He was born at Mons in 1520, and died at Munich in 1593. Living to a great age, the number of his works exceed those even of Palestrina. Fifty collections of his different works are still extant, consisting of masses, motetts, passions, psalms, and songs or madrigals, printed in Italy, Germany, France, and the Low Countries. Such was his reputation, that the following verse was written for his epitaph:—

Hic ille Orlandus Lassum, qui recreat orbem.

M. Ginguene, to whom we are much indebted for the account of the restoration of music, speaking of Cypriano Rore and Orlando di Lasso, says, "These two Flemings, having passed the greater portion of their lives in the courts of princes, had acquired a lighter style, and a species of melody more appropriate to secular music, than that of Palestrina, who, residing at Rome, and writing principally for the church, exhibits in all his productions a gravity belonging to the species." And again, "They were two masters of harmony; and, the church excepted, they prepared the colours and set the palettes of musicians with many new tints of harmony and modulation, which were exceedingly serviceable to those who came after them." These were the two first masters who ventured upon chromatic passages, and upon accidental flats and sharps. From the epoch of these men Flanders ceased to have a school of music especially belonging to itself.

French Music.—We have stated, in another place, that Hubald de St. Amand and Eudes de Cluni have been named by the French writers as having preceded Guido in the knowledge of the scale; but, as we are not in a condition to decide between the claimants, we shall content ourselves with the declaration of our conviction, from all that we have read, that France, as respects the art and science of music, was much advanced at a very early period, and that the country certainly boasted of many church musicians between the 8th and 11th centuries; for, besides the two we have named, we have Remi, a monk of St. Germain d'Auxerre, Gerbert le Scholastique, and others whose knowledge is well authenticated. In the 14th century Philippe de Vitry, archbishop of Meaux, applied himself to music and poetry with considerable success. A manuscript preserved in the Vatican proves him to have been well informed upon counterpoint, as far as it was then known and practised: he not only applied himself to church music, but wrote motetts; but these are lost, and perhaps would, if we had them, be now difficult to decipher. Belonging to this century, also, we have, by the assiduity of the Abbé le Bœuf, the account of a manuscript by Guillaume de Machau. This MS. consists of two volumes of French and Latin poems, and a great number of *lays*, *virelays*, *ballades*, and *rondeaux*, all set to music; some for a single voice, others in three and four parts,—triplum, tenor, contra-tenor, and a part without title. In the second volume is an entire mass, including the *Credo*, in four parts, which it is believed was sung at the coronation of Charles V. in 1364.

During the 15th and 16th centuries, the art made but little progress in France. Under Francis the First not near so many musicians were to be found in France as in Italy, Germany, England, and the Low Countries. The works of Claude de Jeune, who probably ought to be placed with the Flemish school, and of Orlando di Lasso, seem to have been admired and performed at this period in the country in which Josquin was also a favourite. The dearth of writers on the science at this period is no less remarkable. There is, however, one singular work of this period, by Clement Jaunequin, entitled *La Bataille ou Defaite des Suisses a la Journée de Marignan*, in which imitations of the sounds of battle occur. He published a collection in 1544, called *Inventions Musicales a quatre et cinq Parties*. The masters about this period were Didier Lupi, Guillaume Belleu, Philibert Jambe-de-fer, Sauterne, and Noë Faignent. It is extraordinary that some of the bloodiest tyrants have been great patrons of music and its professors: to Nero and our Henry VIII. may be added, for France, Charles IX., about whom were constantly good musicians. Of them, Claude Gondimel did not escape, in the massacre of the Protestants at Lyons in 1572. At the end of the 16th century were some minor

artists, such as Jean de Castre, Louis Bisson, Nicholas Duchemin, Francois Roussel, Jean Peroin, and others, by whom are collections of madrigals. Francois Eustache de Caurroy, born in 1549, called, by his cotemporaries, "le prince des professeurs de musique," was maestro di capella to Charles IX., Henry III., and Henry IV., and enjoyed considerable reputation; his works, however, are but little above mediocrity. Jacques Mauduit was a similar instance of mediocrity rising into celebrity. He composed the requiem for the funeral of the celebrated Ronsard, which was afterwards performed at that of Henry IV., whose reign was too short to allow the arts of peace to make much progress in France. His son, who came to the throne at the early age of six years, was a great friend to music, and appears to have kept up what might be called a considerable band for that period. During the reign of Louis XIII., Jean Baptiste Boesset wrote several part songs, as they were called. About the middle of the 17th century Michael Lambert, who died in 1696, appears to have attracted many scholars by his skill in composition. Dramatic music was introduced into France about 1645. In 1660, at the celebration of the marriage of Louis XIV., the opera of *Ercole Amanti* was produced, and the foundation of the French opera was thus laid. At this period Lulli, of Florentine birth, had been patronised by the Chevalier de Guise, through whose offices he was put under the best masters of the time. Till the year 1686, in which his last opera was brought out, he seems to have been the idol of the court, and to have been considered in France the *ne plus ultra* of composers. Compared, however, with the Italian opera of the same epoch, his compositions are not far behind, though it was a misfortune for the country that, for so long a period, every thing which was not an imitation of the style of Lulli was considered an inferior production. Instrumental music made but little progress in the 17th century. The most distinguished organists were, the three Bournonvilles, and the three Couperins; Charbonieres, who died in 1670; Dumont, a good composer of church music, who first introduced violin accompaniments into France; the Abbé de la Barre; and, lastly, Lalande, the most celebrated French composer of ecclesiastical music, at the end of the 17th and beginning of the 18th century. Rameau, born at Dijon in 1683, was destined to rouse the French nation, which seemed to have slept since their loss of Lulli. In the space of twenty-seven years after 1733 he produced 22 operas, and became so great a favourite with the people that it was dangerous to criticise his works. The time has, however, passed in which his operas would be listened to; and but for his theoretical works, the only solid base of his glory, he would long since have been forgotten. Rameau died in 1767. His school lasted till about 1775, though since 1750 the comic opera has been on the Italian model. Under this, with Dauvergne, le Borde, Floquet, J. J. Rousseau, Duni, and Philidor, French melody has regenerated; and Monsigny, Gossec, and Gretry completed its improvements. The reform thus effected prepared the French for the reception of the *Iphigenie* of Gluck, in 1774, at which time he had Piccini and Lucchini for rivals. These musicians have been succeeded by a school which comprises the names of Berton, Mehul, Boildieu, Kreutzer, and others; and among the Italians who joined their ranks are found those of Cherubini, Spontini, and Winter. In instrumental composition the French have not been so original, though latterly they have considerably advanced. France is considered deficient in musical literature, and does not attend to its cultivation with that ardour that is so manifest in Italy and Germany. Their conservatory, however, is an establishment likely to do honour to the nation; and the work of Choron, — entitled *Principes de Composition des Ecoles d'Italie, adoptés par le Gouvernement Français, pour servir à l'Instruction des Eleves des Maîtrises de Cathedrales. Ouvrage classique, formé de la Reunion des Modeles les plus parfaites en tout genre*, in 3 vols. fol., — is alone sufficient to redeem the French from the accusation of wanting musical literature.

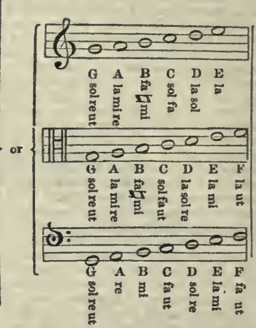
English music.—We are not acquainted with writers in this country of earlier date than those of Italy; but, for the honour of this country, however much we may have been behind Italy in the restoration of other arts, in that of music we were formerly quite on a par with the Continent; and it is singular that in later years we should have lost our character, and we fear deservedly, among other nations. It is certain that England can boast masses in four, five, and six parts, written by natives, as ancient as those of the Italians themselves; we have also secular music in two and three parts, and in good counterpoint, in the latter end of the 15th and beginning of the 16th century, about which period to the English musician the names of William of Newark, Sheryngham, Turges, Tudor, Banester, Browne, and others, are familiar. The first named was one of the musicians of Henry VI.; and the compositions of Tudor are known from Prince Henry's (Hen. VIII.) music-book. Henry VIII. is known as a composer, from a beautiful anthem in Boyce's collection of cathedral music; and his patronage of Christopher Tye, the composer of *Laudate Nomen Domini*, a motett frequently sung at madrigal meetings in the present day, shows that good music was then first esteemed as it ought to be. Marbeck, in 1550, published the whole of the reformed cathedral service to musical notes, and for his exertions as a reformer he had nearly been brought to the stake. During the reign of Elizabeth the talents displayed by our countrymen appear to have been surpassed in no other country, and music here was then indeed in its palmy state. Tallis, Bird, Morley, Dowland, and Bull, were the principal composers of the reign: Elizabeth herself could have been no mean performer, if she was able to play the pieces in her virginal book. Though it does not appear that James I. took much delight in music, it nevertheless continued to prosper during his sway; indeed, the compositions of Gibbons were, as pieces of church music, perhaps never surpassed in any age or nation: neither are his secular pieces of inferior character. This reign as well as the preceding was fruitful in madrigal writers as well as composers for the church; among the former of whom were Michael and Thomas Este, Bateson, Ward, Litchfield, Pilkington, Wilbye, Bennett, Farmer, Ford, and others; and among the last Tomkins, Elway Bevin, and Dr. Nathaniel Gyles. In the time of Charles I. instrumental music was coming into vogue; the monarch was a pupil of Cooper (who was wont to be called Coperario), and used to practise the viol-di-gamba. He had a band of performers, eighteen of whom are known, including Nicholas Laniére, who was the master of it. The most celebrated men of this reign were Dr. Wilson, William and Henry Lawes, and Dr. Child, who died in 1697, aged 90, after having been organist of St. George's chapel, Windsor, during the extraordinary period of sixty-five years. So intent was Charles upon advancing music, that he granted a charter to the most eminent musicians of that day, with many great privileges. The art had been sinking for some years, but its fall was accelerated by the suppression of the cathedral service in 1643; and the only persons of whom we hear during the time of Cromwell were William and Henry Lawes. Though these men were favourites of Milton, and the subject of some of his verses, they were sadly inferior to Tallis, Bird, and Gibbons. During the interregnum the musical flame was chiefly fed at Oxford; but even there, from the year 1646, in which the king was forced to leave the city, after the battle of Naseby, until 1656, it was nearly extinguished. At the Restoration it appeared again to flourish: Child, Christopher Gibbons, Rogers, and Wilson, were made doctors of Oxford; the choirs again obtained good masters; and the organs, which had been destroyed by the fiend-like rage of the Puritans, were again set up, though with difficulty, from the scanty supply of organ-builders. Among the musicians who were attached to the court of Charles II. was Henry Purcell, of whom Dr. Burney says, that he, "during a short life, and in an age almost barbarous for every species of music but that of the church, manifested more original genius than any musician under similar circumstances, that any inquiries into the history of the art have yet discovered in any part of Europe." This truly great man died Nov. 21. 1695, in the thirty-seventh year of his age; his principal contemporaries were Dr. Blow, his master, Pelham Humphreys, and John Weldon. After Purcell's death some skilful men appeared as amateurs in the service of the church; namely, Doctors Holder, Aldrich, and Creyghton: among the professors were Jeremiah Clarke, Goldwin, and Doctors Croft, Green, Boyce, and Nares. Croft of all these was undoubtedly the greatest; he, like Purcell, was a disciple of Blow: always elegant and simple in his strains, frequently grand and masterly, he has not left a composition that does not exhibit great learning. His death occurred in 1727, in the fiftieth year of his age. Dr. Boyce occupied the void which Croft's death had created; he was a good musician, always pleasing, but rarely grand in his compositions. His contemporary, Jonathan Battishill, wrote some fine compositions for the church, and prepared the way in glee writing for a race of English musicians who are an honour to their country. The reader will recognize the truth of this assertion when he glances at the names of Alcock, Arne, Attwood, W. Beale, Callcott, Dr. Cooke, Robert Cooke, Crotch, Danby, James Elliott, Harington, Horsley, Thomas Linley, the Earl of Mornington, Shield, Stafford Smith, Spofforth, the Wesleys, &c. In dramatic and symphony writing, we regret to say, England is still in her infancy.

Chinese Music.—The Chinese have had a system of music from a most remote period, and in its scale it seems to have more resemblance to the Grecian than any other to which it could be compared. From the time of Yao and Chun, which their chronology would carry back two-and-twenty centuries before Christ, they have had what they call eight species of sounds: 1st, The sound of dried skins, such as drums; 2d, The sound emanating from stone, called *king;* 3d, That of metal, as bells; 4th, That of baked earth, called *hiven;* 5th, That from silk, called *kin* and *che;* 6th, That from wood,

called *ya* and *tihou;* 7th, That from bamboo, such as flutes, called *koan;* 8th, That from the gourd, called *cheng*. Their scale consists of 14 notes, of which the seven middle notes correspond to our gamut from *f* upwards. They seem unacquainted with harmony, and we ought, perhaps, to apologise for saying so much of it.

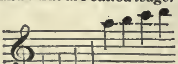
Hungarian Music.—About the 9th century the Hungarians left Asia to settle in Europe, when they conquered the country that bears their name. Like all the Asiatics, they were attached to music, and at first, doubtless, used only Asiatic instruments: these were nearly all wind instruments, and consisted of the trumpet, the flute, the cymbal, and several others. Till the time of Mathias Corvin it was in a state of mediocrity; he incited the Hungarians to vie with other nations in sciences and arts, of which he himself was particularly fond. Under Ladislas and Louis II. music was cultivated with great care; their national songs were, however, the only vocal music they possessed till the time of Stephen, king of Hungary, when the ecclesiastical chant appears to have been introduced. In a diploma of Bela III., A.D. 1192, it appears that prince sent an envoy to Paris to be instructed in melody; perhaps induced to do so by his second wife Margaret, who was daughter of Louis VII. of France.

All musical ideas are expressed by means of *notes* on a *staff;* that is, five equidistant horizontal lines, on or between which the notes are placed. The *gamut* is a table whereon these notes are placed; and their relative situations as to acuteness or gravity of tone is ascertained by *clefs*. The names of the notes, which are six in number, are *ut, re, mi, fa, sol, la*, the lowest of these being the gamma of the scale. Modern musicians have used as equivalents the first seven letters of the alphabet. The arrangement in question is exhibited in the diagram below, a note having been added by the moderns to complete the octave.



From this diagram it will be seen that the bass clef, also called the F fa ut clef, on whatever lines placed, makes the notes on the line between the dots F or fa ut, whence reckoning is made upwards or downwards; that the tenor or C sol fa ut clef makes all the notes on the line between the cross or horizontal bars or sol fa ut; and that the treble or G sol re ut clef makes all the notes on the line round which the character turns G sol re ut; and it is to be observed that these several clefs may be put on any lines of the staff notes, which then take the name F, C, or G, as the case may be. Thus,

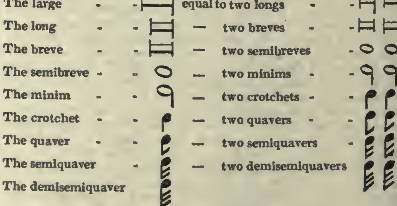
One of the most important ends gained by the use of these clefs is the avoidance of notes running off the staff, which they otherwise would do, and what are called *ledger* lines would be wanted; thus,



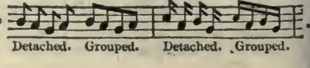
where the ledger lines are those upon which the notes out of the staff are placed. The lines of a staff are reckoned upwards; thus the lowest line is called the first, the lowest but one the second, and so on. When the F clef is placed on the third line, it is called the *barytone* clef; when on the fourth, the *bass* clef. When the C clef is placed on the first line, it takes the name of the *soprano* clef; when on the second, the *mezzo soprano;* when on the third, the *alto* or *countertenor* clef; and when on the fourth, the *tenor* clef. The G clef is rarely or never now placed on any but the second line, and is then called the *treble* clef. It may be sometimes seen in old books placed on the first line; when so found, it is called the *high treble* clef. In keyed instruments the C nearest the middle of the instrument is the note of the tenor or C clef; the G above it to the right is the treble or G clef; and the F below to the left is the F or bass clef note. When to the seven primary notes (see diagram) another is added above, the arrangement is called an octave; thus,

After which, if more be added either upwards or downwards, it will be but a return to similar notes either more acute or more grave in pitch; that is, an octave above or below them respectively. This, which is called the *scale*, has between its notes seven intervals, of which those between *c* and *d*, *d* and *e*, *f* and *g*, *g* and *a*, and *a* and *b* are equal, and are called *tones* or *whole tones;* whilst those between *e* and *f* and *b* and *c* are *semitones*. To inquire how nature has implanted on the ear dissatisfaction from any other position of these semitones in the scale of the octave, is not the object of this treatise. That it is so is certain; and the most uneducated whistler could not avoid it without exertion. The scale is also divided into two *tetrachords*, from *c* to *f* and from *g* to *c:* each of these consists of two tones and a semitone. There is not a strict mathematical equality between these fourths; but for our purpose here—and the difference indeed is imperceptible except to the finest ear—that equality may be assumed. As all *melody* or *air*, which is an artful succession of tones, depends on a right perception of the places of the semitones, the above preliminaries must be well understood by the student.

By the particular form of a note its duration, or length of time it is to be held on, is known. There are nine of these forms, which are exhibited in the subjoined table, in which the two first are now rarely used, though in old ecclesiastical music they are constantly met with.



The notes with hooks appended to their tails are frequently grouped together; this does not alter their value, but it assists the eye in reading off the proportions of the notes. Thus,



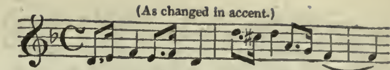
If a dot be added to the right hand of any note, thus ♩·, it increases its duration exactly one half. The duration of a note is measured by the musician from habit, and is regulated by *beating time;* that is, by the elevation and depression of the hand or foot quicker or slower according to the nature of the music performed. A musical piece is divided into *measures*, which are equal portions of time; and the vertical lines which so divide it are called *bars*, single lines taking merely that name; and the two thick ones at the end of a strain *double bars*. Thus, . Every measure must contain a certain number of notes according to the time marked at the beginning of the movement; and that time is of two sorts, — *common time* and *triple time*, — in which two all others originate. The first is of two sorts: 1st, that in which each bar is equal to a semibreve in duration; 2d, that in which a minim in duration is equal to a bar. Those common times in which a semibreve is the measure are marked by a C after the clef at the beginning of the staff; thus, . When the C has a bar through it, thus , it denotes a quicker measure, thus 
, and is called *alla breve*, but it is now usually written by dividing the breve into halves. There is another sort of movement now very rarely used; it is very quick, and it is thus marked, . The other characters of common time are ; signifying that there are two crotchets in the bar, of which (the denominator) four make a semibreve. Triple time is so called from the bars being divisible into three parts: it is beat with the hand down at the beginning of the bar, raised a little in the middle, and quite up at the close of it. In this time the denominator of the figures placed at the beginning of the staff is a measure of a semibreve: thus, if 2 be the denominator, the measure is a minim, because two minims make a semibreve; if 4, the measure is a crotchet; and so on. Hence  signifies three minims in a bar;  three crotchets;  three quavers. So again with multiples of 3 for the numerator:  signifies three crotchets;  six quavers;  nine quavers;  nine semiquavers;  twelve quavers. Other sorts of triple time are used; but if the reader keep in mind that the denominator always expresses the division of the semibreve, and the numerator the number of those divisions in each bar, no mistake can ever arise.

There is a certain stress laid on some part or parts of every bar, which is called *accent;* hence each bar or measure is divided into accented and unaccented parts: the accented are the principal, and those on which the pathos and spirit mainly depend. The beginning and the middle, or the beginning of the first half of the bar and the beginning of the latter half, in common time, and the beginning or first of three notes in triple time, are universally accented parts of the measure; so the first and third crotchet of the bar are on the accented part of the measure in common time. In triple time, where the notes, as we have explained, go by threes, the note in the middle is unaccented, and the first and last accented; the accent, however, on the first is so preponderant, that the last is almost accounted as though it had none. It is on account of accent that it is frequently necessary to begin a movement with only part of a measure. Thus in the Welsh tune *Griffith ap Cwnan*, —

(As written.)

it will immediately be seen that the alteration of the accent entirely changes

(As changed in accent.)



the character of the air. When the last note of a bar (as in the last bar of the lower example) is connected with the first of the following bar, so as to make only one note of both, it is called *syncopation*. This is also sometimes used in the middle of a measure; also when a note of one part ends in the middle of a note of the other: the latter, however, is called *binding* or *legature*.

A *rest* is a pause or interval inserted when silence is required in the part to which it is written, which silence is to be preserved during the time denoted by the species of rest used. The following are the rests that are used: —

Long. Breve. Semibreve. Minim.

Crotchet. Quaver. Semiquaver. Demisemiquaver.

It has been already noticed that in the ascent of a note to an octave, there are between the third and the fourth note, and between the seventh and the octave, semitones instead of whole tones; and this is what is called the *diatonic scale*. It must therefore be evident, from this inequality, that supposing it were necessary, for the sake of the voice's compass or any other cause, to commence a piece of music higher or lower than it was originally written, the mere shifting the notes higher or lower on the lines and spaces would not represent the same relative proportions in all the intervals; because the places of the semitones would remain the same on the staff, whilst their position with respect to the notes would be altered. An expedient is therefore wanted by which the places of the notes may be raised or depressed the value of a semitone. The former, that is raising them, is effected by placing sharps before them, thus ♯; and the latter by means of flats, thus ♭. If we want to restore any note that has been thus treated to its original place, it is effected by means of a natural, thus ♮. Two other characters are also used, — the double sharp, thus ×, which raises a note two semitones; and the double flat ♭♭, which equally depresses it. Upon keyed instruments, such as the pianoforte and organ, these sharps and flats are represented by the short black keys, and there is no distinction between D♯ and E♭, and such want of distinction is an imperfection in the instrument; for, as we have before hinted, there is not a strict mathematical equality between the semitones of the diatonic scale. The number of these flats and sharps at the beginning of a staff affect all the notes of the line or space on which they are placed, and are termed the *signature*. If, in addition to these, in the course of a movement any other occur, they are termed *accidental*, and only affect the notes which they immediately precede, and those also in the same bar; but if in the same bar any note after having been accidentally raised, on being repeated is preceded by a natural, such natural restores it to its original place.

The ornaments of musical melody are called *graces;* the principal of which are the *appoggiatura*, the *shake*, the *turn*, and the *beat;* with the *mordente*, *beat*, *slide*, and *spring* peculiar to the Germans: those of musical harmony are the *arpeggio*, the *tremando*, &c. The appoggiatura, which always occurs on the accented part of the measure, is a small note placed before a large one of longer duration, which it usually deprives of half its value; thus, , wherein the small notes are appoggiaturas. Occasionally, the appoggiatura is only one quarter of the note it precedes. The shake is a quick alternate repetition of a note with the note above it, the mark *tr* being placed on the lower, and the upper one not expressed; thus 
, performed . When there are a series of ascending or descending shakes, the Italians call it *una catena di trilli*. What the Germans call the *passing shake* is thus marked over the note where it is intended, thus , performed 
The mordente of the Italian school is used similarly;

thus , performed . The turn employs the note above and that below in the following way, ; performed . The inverted turn, thus marked ~, turns from the note below that marked instead of above it. Turns on dotted notes are very frequently used; they are written as follows  performed . The beat is the reverse of the shake without the turn, and is generally made at the distance of the semitone below; hence all the natural notes, except C and F, require the note below them to be accidentally sharpened for the beat; thus , performed . The half-beat is most frequently used in the bass, and is very similar to the acciacatura of the Italians. The inferior note is struck only once, and at the same time with the principal note; but is immediately quitted, as . The Italians use the degree above. The German mordente is a beat commencing with the note itself, and is either long or short; thus,  . This differs

(long) (short)

from the mordente we have already described by being made with the next degree below. The Italians use the degree above. The German beat consists of two small notes, forming a skip, descending one degree upon the principal note; written thus , performed . Naumberger calls this grace a double appoggiatura. The German slide consists of two small notes, which move by degrees; written thus , performed . The German spring, like the Italian mordente, consists of two small notes, sounded distinctly; thus , performed . It is the practice of the composer to mark, where necessary, the occasional alteration of these graces by sharps, flats, or naturals. The graces that belong to harmony are, the *tremolo*, or reiteration of one of a chord; the *tremando*, or general trembling of the whole chord; and the *arpeggio*, which is an imitation of the harp, the notes of the chord being struck in quick and repeated succession. The following characters are also used in Music:—the *pause* 𝄐, which, placed over a note, signifies that a long continuance of the sound is to be made on that part of the measure, and is equally effective when placed over a rest; the *repeat* 𝄋, which is a sign placed to show where the performer must return to repeat the passage,—the Italians call it *il segno*; the *direct* w, always placed at the end of the staff on the line or space which the following note occupies. The dots which are found in the inner side of bars show that the measures or bars included by them are to be repeated; thus, , shows that these two bars are to be played twice over, the same object being sometimes effected by writing the word *bis* over them.

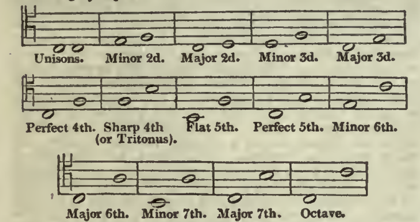
We have already mentioned the single and double bar; all that we have to add on them here is, that as every bar or measure contains a certain number of notes, so every *strain* consists of a certain number of measures, which are terminated by the double bar.

Expression, in music, is indicated by the following marks:—The *tye*, which is a convex line over ⌒ or a concave line under ‿ two notes on the same line or space, uniting them into one. It is also used to express syncopated notes where the bar divides them. The *slur* is a similar line, used over notes not on the same lines or spaces, showing that such notes are to be played smoothly; and in vocal music it also means that all the notes connected by it are to be sung to the same syllable. The *dash* is a small vertical stroke ǀ placed over notes that are to be distinctly marked. Sometimes, instead of this, the *point* is used, though it is mostly employed to distinguish those notes from which an intermediate effect between the slur and dash is wanted, yet uniting the one and the other; thus, . The other marks of expression are the *crescendo* <, by which the sound is to be increased from soft to loud; the *diminuendo* >, which is exactly the converse of the last,—the union of these two <> indicating that the first part is gradually increased from soft to loud in the middle, and then to soft again; and the *rinforzando*, for which smaller marks of the same sort are used > <, which increase or diminish the sound so marked. In order to save time in writing and copying music, the following abbreviations are used:—A single stroke placed over or under a semibreve, or through the stem of a minim or crotchet, divides it into quavers, a double stroke into semiquavers, and a triple stroke into demisemiquavers; thus, . The other kind of abbreviation is much used in modern music, and is effected by grouping the stems of minims like those of quavers; thus , performed .

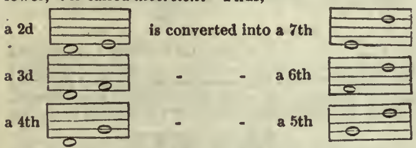
Melody, which will be perhaps better understood by the term *a tune*, is a particular succession of sounds in a single part, and is produced by the voice or an instrument. The artful manner of introducing the notes of different lengths, and succeeding one another at intervals pleasing to the ear, is one of the desiderata of the musician; the other being the successful accompaniment of these single sounds by others, according to the laws of harmony. As respects tune or air, melody has two motions,—either by degrees or by skips: by the former when it moves to the line or space immediately above or below it; and by skips when one or more degrees are omitted between the preceding and following note. The following example shows each motion .

The distance between any two notes is called an interval, and it is customary to measure it from the lower of the two notes which by their names indicate the number of degrees whereof the interval consists; remembering that in the diatonic scale whole tones are divisible into semitones. It may be as well to explain here the term *diatonic*. It is derived from two Greek words, *δια*, *through*, and *τονος*, *a tone;* because, through the majority of notes in this scale, it proceeds by whole tones, five out of the seven being of that description, and the other two being semitones. And again, that the notion of an interval between sounds may be properly acquired and felt, we would hint that it may be comprehended by stretching a string between two fixed points so that upon being struck its vibrations are free and will yield a sound. Now a string half the length similarly stretched will yield a sound exactly one octave higher; the intermediate lengths, therefore, between 1, which we will assume the first string to have been, and ½, the length of the second at a certain place, according to a certain ratio, will yield the different sounds of the octave: thus we may acquire a distinct notion of intervals of sound by absolute intervals of length. To return, then, to different intervals in the octave. If we count from the lower note to its octave, there will be found the following intervals:—First, the *unison*, which in harmony is

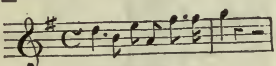
accounted an interval, though it be the same identical sound. Second, the *minor second*, sometimes called the *flat second*, is the interval formed by two sounds at the distance of a diatonic semitone from each other. Third, the *major second*, consisting of a whole tone. Fourth, the *minor third*, containing a whole tone and a diatonic semitone. Fifth, the *major third*, consisting of two whole tones. Sixth, the *perfect fourth*, containing two tones and a diatonic semitone. Seventh, the *sharp fourth*, containing three whole tones, and called thence by the ancients the *tritonus*. Eighth, the *flat fifth*, containing two tones and two semitones; which, however, are not equal to three whole tones, but rather to two minor thirds. Ninth, the *perfect fifth*, containing three tones and one semitone, equal to a major and a minor third. Tenth, the *minor sixth*, consisting of three tones and two semitones. Eleventh, the *major sixth*, which consists of four tones and one semitone. Twelfth, the *minor seventh*, containing four tones and two semitones, or ten semitones. Thirteenth, the *major* or *sharp seventh*, composed of five tones and one semitone, or eleven semitones. Fourteenth and last, the *octave*, consisting of eight degrees. The above fourteen intervals are given in the following synopsis:—



By inserting the semitones between these intervals, the number which we have above stated in each will be easily discovered. When the lower note of any interval is placed an octave higher, or the higher note an octave lower, it is called *inversion*. Thus,



By this operation major are converted into minor intervals, and the converse; for instance, the sharp fourth becomes a flat fifth, and the unison becomes an octave. We will here mention an ancient division of melodies, which at least ought to be understood by a student,—namely, into that of *authentic* and *plagal* melodies. The former are those whose principal notes are between the key note and its octave, of which the following is the example given by Calcott, in his Grammar, from Handel's *Jephtha*,—



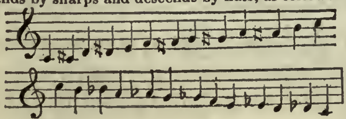
(Waft her, angels.)

The latter, on the contrary, have their principal notes contained between the fifth of the key and its octave, or twelfth; as,

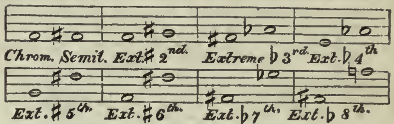
(Streams of pleasure.)

from Handel's *Theodora*.

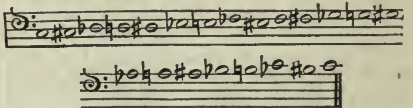
There are three scales occasionally used in music: the *diatonic*, which has already been explained; the *chromatic*; and the *enharmonic*. The chromatic,—which, according to some, takes its name from the Greek word χρῶμα, *colour*, because they suppose the Greeks distinguished it by different-coloured characters; according to others, because holding the mean place between the diatonic and enharmonic system, it was like colour between black and white; or, as others say, because, like colours in painting, it embellishes the diatonic by its semitones,—usually ascends by sharps and descends by flats, as follows:—



From this it appears that the chromatic scale consists of thirteen tones, with twelve intervals between them, whereof we have already, among the diatonic intervals, described seven; the other five form a distinct species of intervals called *chromatic*. First, the *chromatic semitone* is the interval between any note and the same depressed by a flat or raised by a sharp. Second, the *extreme sharp second*, which consists of a tone and a chromatic semitone, being composed of two degrees. Third, the *extreme flat third*, which contains two diatonic semitones, consisting of three degrees; or it is the minor third diminished by a chromatic semitone. Fourth, the *extreme flat fourth*, containing a tone and two diatonic semitones, and consisting of four degrees; or it is the perfect fourth diminished by the chromatic semitone. Fifth, the *extreme sharp fifth*, which is the perfect fifth increased by the chromatic semitone. Sixth, the *extreme sharp sixth*, or the major sixth increased by the chromatic semitone, consisting of five degrees; it is divisible into a major third and sharp fourth. Seventh, the *extreme flat seventh*, or the minor seventh diminished by a chromatic semitone; it is composed of four tones and two diatonic semitones, and is divisible into three minor thirds. Eighth, the *extreme flat eighth*, or octave diminished by the chromatic semitone. This is never used in melody. The above intervals are exhibited in the subjoined synopsis.



The enharmonic scale, so called from the augment εν, and signifying extremely harmonious, or well knit together, is a series formed by uniting the ascending and descending scale of the chromatic genus. It contains intervals smaller than the semitone: not, indeed, exactly half the semitone; but, from their near approximation to it, called the *diësis*, a Greek word signifying *a division*. We have before hinted that there is not a strict mathematical equality between the tones in an octave. Our limits do not permit to pursue that question further than to say, that that tone which is between the fourth and fifth of the scale is divided into nine small parts, called *commas;* whilst that between the fifth and sixth of the major scale contains only eight commas. The diatonic semitone contains five commas; and the chromatic semitone three or four, according to the magnitude of the tone. Now the enharmonic scale divides each tone into two chromatic semitones and a quarter tone; but we subjoin a diagram of it.



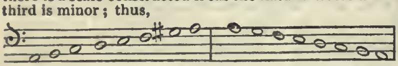
In this scale we have inserted the intervals E♭ and and E♮; also C♭ and B♮; but they do not properly belong to the scale, as their distance is less than a quarter tone. We have omitted above to state that there is another interval, which, by calculation, is found to be a comma and a half, and is called *hyperoche*, or an *excess*.

As in oratory there is a principal subject whereon the speaker constantly dwells, and to which, after diverging from it, he always returns; so in music there is one sound in which the piece begins and ends, which regulates the rest, and to which regard must be had in all the other sounds of the piece; and this sound is called the *key*, and the principal note the *key note*, or *tonic*. From the diatonic scale we have seen that the semitones lie between E and F, and B and C; the key note being C. Now if we wish to make G the key note, it is clear that without some contrivance the writing the notes from G to its octave will throw one of the semitones out of its place; namely, that between E and F, which, instead of being, as it ought to be, between the seventh and the octave, is between the sixth and the seventh. It is obvious, then, if we raise the natural F a semitone by means of a ♯, we shall restore the semitone to a situation similar to that which it held in the key of C. By comparing the subjoined scales, this will be more distinctly seen.

Now if D be taken as the key note, we shall find it will be necessary to sharpen the C as well as the F, in order to bring the semitones into the places they ought to occupy in the octave; and we shall have two sharps. In order to save the constant repetition of these sharps, it is usual to put them at the beginning of the staff, where they are called *signatures;* thus,

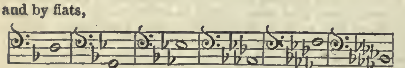
In the same way the keys bearing flats are marked, saving that the seventh of the original key bears the first flat, as follows:—

Besides these scales, which are all constructed with the major third, and are therefore called major keys, there is a scale constructed from the natural notes whose third is minor; thus,



In which it must be observed, first, that the places of the semitones are different; and, second, that the ascending scale always requires the seventh to be sharpened, though it is not sharpened in the descending scale. The sharp in question is, however, always omitted in the signature, and marked accidentally where the melody requires it. It must be here noted, that between the F♮ and G♯ a harsh chromatic interval, called an *extreme sharp second*, occurs; to avoid which the sixth is sharpened, by which the scale of the minor mode has two notes different from the signature; but in the descending scale no accidentals are required. The minor modes, whether proceeding by sharps or flats, have exactly the same signatures as the major mode. Thus by sharps we have

and by flats,

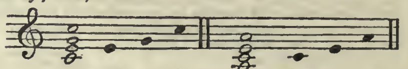


Major and minor scales which have the same signatures are denominated *relative*. Thus the relative minor keys of A is E ♮; in which case the tonic or key note of the minor mode is found to be the sixth note ascending of the major scale bearing the signature; and the tonics are always one degree below the last sharp of the signature, but in flat signatures always the third degree above the last flat.

The change of a melody from its original to a higher or lower pitch is called *transposition*, and this may be effected by altering the signature according to the pitch of the new tonic or key note. This alteration may be also accomplished in every minor melody. If a melody is performed in the relative or tonic minor being originally major, the change is not called transposition, but *variation*. *Modulation* is the motion of the melody on the key in which it has commenced, and the alteration by new flats and sharps of the original scale. Modulation comprehends the regular progression of several parts through the sounds that are in the harmony of any particular key, as well as the proceeding naturally and regularly from one key to another. Every scale is immediately connected with two others: oneon the fifth above, which adds a sharp to the signature; the other on the fifth below or fourth above, by which a new flat is added to the signature. These were called by Dr. Boyce *attendant keys*. Minor scales have in like manner their attendant keys.

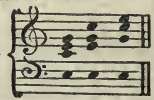
We here subjoin, from the late Dr. Callcott's excellent Musical Grammar, the names given to certain notes in the scale as peculiarly marking their character, though we do not intend to use them in the following part of this short essay. 1st, The *tonic*, or key note, is the chief sound upon which all regular melodies depend, and with which they all terminate. All its octaves above and below are called by the same name. 2d, The *dominant*, or fifth above the key note, is that sound which from its immediate connection with the tonic is said to *govern it;* that is, to require the tonic to be heard after it, at the final cadence in the bass. 3d, The *sub-dominant*, or fifth below the key note, is also a species of governing note, as it requires the tonic to be heard after it in the plagal cadence. It is the fourth in the regular ascending scale of seven notes, and is a tone below the dominant; but the term arises from its relation to the tonic, as the fifth below. These three principal sounds are the radical parts of every scale, of the minor as well as the major; and all melodies are derived from them. 4th, The leading note, or sharp seventh of the scale, is in Germany called the *subsemitone* of the mode; it is always the major third above the dominant, and therefore in the minor scales requires an accidental sharp or natural whenever it occurs. 5th, The *mediant*, or middle note between the tonic and the dominant ascending, varies according to the mode; being the greater third in the major scale, and the lesser third in the minor scale. 6th, The *submediant*, or middle note between the tonic and subdominant descending, varies also according to the mode; being the greater sixth in the major scale, and the lesser sixth in the minor scale. 7th, The *supertonic*, or second above the key note, has seldom been distinguished in England by this or any other appellation. In theory it is considered as a *variable* sound, being a comma higher in the major scale than when the mode changes to the relative minor.

Harmony consists in the combination of two or more sounds or melodies heard at the same moment, the intervals between such sounds having been already defined. A *concord* is an agreeable relation of two sounds as respects the ear, such sounds which are agreeable compounds singly being agreeable also in succession, subject to certain laws. Concord is therefore included under the term harmony, though more properly applied to the agreeable effect of two sounds in consonance; whereas harmony involves the agreement of a greater number of sounds than two. When two sounds either in consonance or succession are disagreeable to the ear, the relation between them is called a *discord*. The concord then may be called a harmonical interval, and the discord an inharmonical one; yet by the proper interposition of discords the harmonies of a passage receive a lustre and value from the contrast. They must, however, as we shall presently show, be properly *prepared* and *resolved*, as it is technically called. The union of any sound with its third (major or minor) and its perfect fifth is called a *common chord;* to which if the octave to the sound be added, we have a combination of four sounds in the harmony; thus,



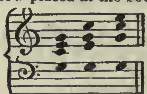
Major. Minor.

So long as in these chords the C or the A remain the lower note, the chord is called the common chord of C or A respectively; but the moment the position of the lower note is changed, the name of the chord also changes. Thus if E of the common chord of C be used as the lowest or bass note, thus



, the chord is called a *sixth;* because the key note is then the interval of a sixth upwards from the bass note, and that sixth has for its accompaniment a minor third from E to G.

If G be now placed at the bottom and used as the bass note, thus



, the key note is an interval of a fourth above the bass, and the chord is called a *fourth*, and, as the example shows, is accompanied by a sixth. From this it is manifest that the sixth and fourth are no more than inversions of the common chord, having the same note C for their expressed or understood bass, which is called the *fundamental bass*, because it is that on which they are founded; and the same arrangement equally exists in the common chord with a minor third. The common chord is expressed shortly thus, $\begin{smallmatrix}3\\5\\8\end{smallmatrix}\begin{smallmatrix}5\\8\\3\end{smallmatrix}$, or $\begin{smallmatrix}8\\3\\5\end{smallmatrix}$; but they are frequently omitted. The second example, or chord of the sixth, is merely figured with a 6; and the third example, where G is the lowest note, is denoted by the figures $\begin{smallmatrix}6\\4\end{smallmatrix}$.

Of discords the most simple is the minor seventh, or, as some call it, the *dominant seventh;* because it occurs only on the fifth or dominant of the key, and requires that part in which it occurs always to descend one degree. We here give its full accompaniment of four real parts

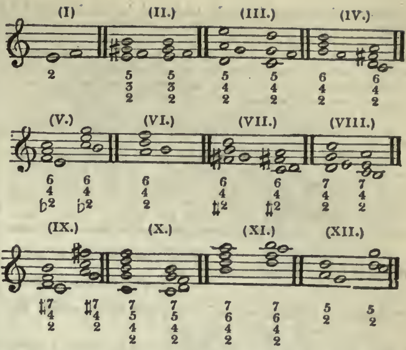
. As in the common chord either of these four sounds may be placed as the bass or lower note of the chord, yet as with C in the common chord the fundamental note of it will be G; B being a

third, D a perfect fifth, and F a minor seventh; thus, ; in each of which cases it would carry the figure 7 below it. Sometimes, however, it is figured below, $\substack{3\\5\\7}\ \substack{7\\5\\3\\8}\ \substack{5\\3\\7}\ \substack{3\\7\\5}$; such positions containing the tenth, twelfth, and fourteenth of the root, when the octave is removed. When B becomes the bass note, as  the chord by inversion consists of a minor third, an imperfect flat or false fifth, and a minor sixth, and is, as in the example, figured $\substack{6\\5}$. If D be next taken as the bass note, thus , the chord consists of a minor third, perfect fourth, and major sixth, and is, as in the example, figured thereunder $\substack{4\\3}$. If F be used for the lower or bass note, thus , the chord is composed of a major second, sharp fourth, and major sixth, and is figured $\substack{4\\2}$.

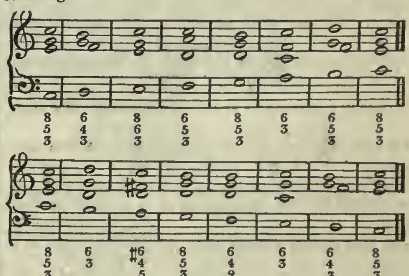
From these observations it appears, therefore, that the three last chords are properly called derivatives of the minor seventh when accompanied with a major third and perfect fifth. By some authors these three chords are called the syncopated fifth, the syncopated third, and the syncopated second respectively. Besides the chords within the compass of the octave, there is the *ninth*, which is usually accompanied with a third and fifth; thus, . When used in a composition of four parts, and marked by a single 9, it has the accompaniment of a third and fifth; thus, . Frequently, however, it is accompanied by a fourth and fifth, and then is marked with a double row of figures; thus, 

When the composition is in only three parts, the fifth is not used. With the third and fifth as an accompaniment the ninth becomes then an appoggiatura, continued in the place of the eighth. The ninth has two inversions: one of them figured with a seventh on the third of the fundamental note; the other figured with a fifth and a sixth on the fifth of the fundamental note.

When the figures 4 and 6 are dashed, thus $\not 4\ \not 6$, it indicates that they represent a sharp fourth and a sharp sixth. It will perhaps be useful, in this place, to place before the reader a synopsis of all the discords: from the seventh upwards they are all inversions of the seventh sharp or flat, with major or minor thirds.



In the above table, I. is the second, and it is the lower note which is the discord; II. contains four real parts without octaves or unisons, and its use is to retard the $\substack{6\\4\\3}$ or $\substack{6\\5}$; IV. is also with four real parts, three of which form a common chord above the bass, which note is the discord; VI. is the imperfect common chord, with a whole tone added below; VII. is the major second, perfect fourth, and minor seventh, and is used to retard the common chord by an appoggiatura in the bass; X. is called the chord of the eleventh, of which the figure 4 is the representation, sometimes called the sharp seventh; XI. is the chord of the thirteenth, — the sixth may be either major or minor; in XII. the fifth must be perfect, the second either major or minor, and either the one or the other may be doubled. The above is a concise view of the *figured* or *thorough bass*, called by the Italians *basso continuo;* and the reader will recollect that all chords may be reduced to the fundamental bass by bringing them to the form of the perfect chord, or to that of the seventh. Chords are called *relative* or *irrelative*, according as a sound is or is not common to both. Thus in , these two chords, which are irrelative, it will be seen there is no sound in either that is common to both; in the chords , the G being found in both chords, they are relative. If in proceeding from one chord to another any note of the previous chord is kept in that which follows, the process will produce correct harmony. The discords, where they appear, must of course be *prepared* and *resolved*, whereof we shall hereafter speak; and care must be taken to avoid progressions of fifths and octaves between the extreme parts when both move the same way. Before leaving this part of the subject, we subjoin, as properly belonging to it, what is called the harmony of the scale; that is, the accompaniment which it carries in ascending and descending: —

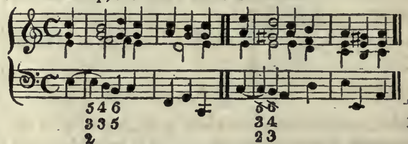


Composition is the art of joining and combining concords and discords in such a manner that their succession and progression may be agreeable to the ear. It may be here mentioned that melody being chiefly the business of the imagination, its rules serve only to prescribe limits to it; beyond which the imagination in searching out the variety and beauty of the airs ought not to go. But harmony is the work of the judgment; and its rules are more certain and extensive, and more difficult in

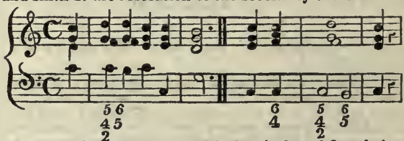
practice. A person, indeed, unskilled in music may by chance make a piece of good melody; but a person of judgment does it with certainty. In harmony, the invention has not so much to do; for the composition is conducted from a nice observation of its rules, assisted also by the imagination. It is not to be expected that in the compass of this article space can be afforded for a complete treatise on this part of the subject; all that we propose is to present to the reader some of the leading rules of the science.

The different motions of the parts which constitute harmony are *direct* and *contrary*. In the former the parts move the same way, ascending or descending. There is also a third motion, according to some, called *oblique motion;* but that may be classed under contrary motion. In direct motion, the parts move the same way, ascending or descending, . In contrary motion, one of the parts rises whilst the other falls, . The use of these motions enables the composer to avoid harmonical irregularities in the use of octaves and fifths, and in other points. The following are the leading rules of harmony, as regards the motions and successions of concords:— First, octaves and fifths must not be consecutive in direct motion. For instance, , where the motion is direct, may be avoided by giving the passage contrary motion; thus, 
Second, unnecessary and distant skips must be avoided as much as possible, and the chords should be kept as close and as much connected as may be. Third, false relations, such as the extreme sharp second, must be avoided, unless the same be required for the purpose of expressing some particular effect. Fourth, the regular motion of the different parts in harmony must be observed: sharp intervals should ascend after the sharp, whilst minor or flat intervals must descend after the flat. In observing this rule, however, that of avoiding consecutive octaves and fifths must nevertheless be observed: neither is to be strictly observed where certain effects are required. It is customary for compositions to begin with one of the perfect concords of its key note, namely, the octave or fifth; and it should end in the key note with its common chord for the harmony. It should not begin or end with a sixth, though it sometimes may with a third. To these we may add, that you must not go from an imperfect concord to a perfect concord by similar motion; such passages being said to contain *hidden* octaves or fifths, which will be seen by filling up the diatonic degrees through which one of the parts is conceived to pass. With these prefatory remarks, we shall now proceed to some few details of the laws of harmony. In proceeding from the unison, when both parts move, it is better to go from it to the third minor than the third major. We may go to the minor either by oblique or contrary motion, ; but to the major it must be by oblique or by similar motion, the first being the best, . A fifth after a unison by similar motion must be avoided: it is good in oblique motion, and is allowed in contrary motion, one part moving a single degree, . From the unison we may go to the sixth minor by contrary motion, : it is not good by the other motions, because of the large leap. But from the unison to the sixth major is forbidden. An octave after a unison except by oblique motion must be avoided, inasmuch as in two unisons or two octaves it is but the division of a large note into smaller.

In the *second*, the lowest note is the discord. It may be *prepared* in any concord, and *resolved* in any but the eighth; it must therefore descend to the resolution, . The *preparation of a discord* is effected by taking care that the note which is the discord is heard in the preceding harmony, its resolution being its descent either a tone or a semitone, according to the mode, after it has been struck. Those seconds are called *transient* which are introduced without preparation on the accented part of the bar, thus ; and if these transient seconds be removed to the accented part of the bar, they then become appoggiaturas. When the second is attended by the fifth and third, it becomes a chord of four real parts, and retards the chord of $\begin{smallmatrix}6\\4\\3\end{smallmatrix}$ or the $\begin{smallmatrix}6\\5\end{smallmatrix}$; and if the third be sharp, the minor mode is indicated.



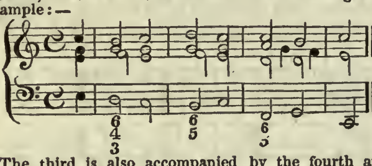
A chord is said to have four real parts when it contains four sounds without octaves or unisons: a concord can only have three real parts. When the second is attended by the fourth and fifth, either the fifth or the fourth must be prepared; and it becomes the chord of the fifth and sixth at the resolution of the second by the bass.



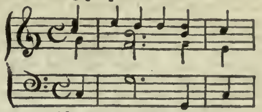
The second accompanied with the sixth and fourth is a chord of four real parts, three of them forming a common chord above the bass, which being the discord must be resolved by a descent to the next degree: the sharp fourth usually ascends, but it sometimes remains stationary, . This chord with the minor second, perfect fourth, and minor sixth, is produced by adding a minor semitone below any common chord with a major third; and also by placing a note one tone below the imperfect common chord, a major second, perfect fourth, and minor sixth; but in all these the second is resolved by descent. The extreme sharp second with the sharp fourth and major sixth is a tone and major semitone below the imperfect common chord. The second major with a perfect fourth and minor seventh retards the common chord with a major third by an appoggiatura in the bass; thus, . The minor second, perfect fourth, and minor seventh retard the common chord with a minor third in a similar manner, . The second is also accompanied with the fourth and sharp seventh, which, when introduced upon a resting bass, allow all the intervals when struck to ascend, . When, however, the

bass moves, it is usual to prepare the upper parts, . The fourth may indeed be used without preparation; but it falls to the resolution. Both the major and minor sixth are used in the chord with or without preparation; but they fall to the fifth, by which the common chord preserves its fulness, . The second may or may not fill up the chord. If the fifth is taken in the chord for the fifth part, it is suspended, and may or may not be in the preceding chord. You obtain the last sixth perfect by it, and retain four single parts in the places where the second is omitted, . The second accompanied with the fourth, fifth, and seventh, , by some is called the chord of the eleventh, the fourth being the representative of that interval, which is always perfect, as well as the fifth; but the second and seventh are major. Accompanied by the seventh, sixth, and fourth, the second is called the chord of the thirteenth, in which the thirteenth is figured by the sixth, which may be either major or minor, . When the second is accompanied by the fifth, , the latter must be always perfect; but the second may be either major or minor.

The third major or minor, , is an agreeable concord; of which it is to be noted that two minor thirds in succession are better than two majors, but mixed thirds in succession are most pleasant to the ear; indeed an octave of major thirds is extremely unpleasant. It is best to begin a regular ascent with a major third, and a descent with a minor, ; and in two parts it is not well to end in a third above the key note. The third is accompanied by a fourth and sixth, , and is generally called the small sixth. That species of it wherein the third is minor, the fourth perfect, and the sixth major, is elegant in effect, as the seventh, from which it is derived. The following is an example:—

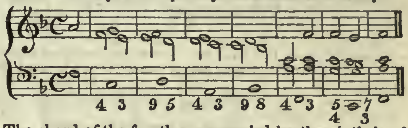


The third is also accompanied by the fourth and seventh; but when the third or the tenth is at the top of the chord, it is generally followed by the $\begin{smallmatrix}9\\7\\4\end{smallmatrix}$, which fourth, seventh, and ninth ought all to descend to the resolution; thus, . The third accompanied by the sixth and seventh is generally followed by the chord of the seventh; hence the sixth is the only interval wanting preparation.

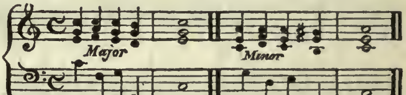


The fourth should not be used alone: it should be associated with the sixth and octave; thus, 

Accompanied by the fifth, the fourth is a discord much used. When introduced on a resting bass, it resolves into the third; and its effect is so similar to that of the ninth, that they are frequently introduced alternately.



The chord of the fourth accompanied by the sixth is of great use in harmonical progressions; and when preceded by the common chords to the key note and fourth of the key, and succeeded by the common chords to the fifth of the key and the key note, forms one of the terminations to a musical period called the fourth and sixth cadence; thus,



When the seventh accompanies the fourth, and that is followed by the chord of the third, fifth, and seventh, either the fourth or seventh, or both, should be in some part of the chord preceding it. In the following example both the fourth and seventh are prepared and resolved:—

When, however, the chord of the fourth and seventh is followed by the fourth, sixth, and eighth, it is frequently used without preparation in either of the positions. The fourth and seventh descend to the resolution, and generally resolve after each other.

The interval of the sharp fourth, which has been before mentioned, is a minor semitone more than the perfect fourth, and a major semitone less than the perfect fifth. Its natural resolution is that the bass shall fall a degree, and the upper part rise one, by which the two parts meet in a minor sixth. It is of very great use in modulation, as you can, by introducing it upon the key note, always change the mode you are in, as in the following examples:—  In four parts the sixth and second are taken with it.

The interval of the imperfect fifth is a minor semitone less than the perfect fifth, and a major semitone more than the perfect fourth. In using this chord the highest note falls and the lowest one rises, so that they meet in a major third; thus, . In four parts it is accompanied by a third and sixth, .

The fifth is the next interval which we have to consider; of this we have already said that two fifths cannot follow each other, except by contrary motion. From the fifth to the unison is good by oblique motion, and also by contrary motion, one part moving a single degree; but by similar motion it is bad. From a fifth to either of the thirds is allowed by all the motions, but it is best by the oblique; next to the oblique, the best way to the third minor is by contrary motion, and to the third major by similar motion, and both by single degrees. A false fifth may succeed a perfect fifth, provided it be also immediately succeeded by a third and by contrary motion,
